PART II.

DISEASES OF HORSES WITH THE METHODS OF CURE.

Before we enter upon theſe particulars we ſhall give

General Directions with regard to the Management of Horſes.

It ought to be laid down as a general rule, to give horſes as few medicines as poſſible; and by no means to comply with the ridiculous cuſtom of ſome, who are frequently bleeding, purging, and giving balls, though their horſes be in perfect health, and have no indication that requires ſuch treatment. Proper management in their feeding, exerciſe, and dreſſing, will alone cure many diſorders, and prevent moſt; for the ſimplicity of a horſe's diet, which chiefly conſiſts of grain and herbage, when good in kind, and diſpenſed with judgment, ſecures him from thoſe complicated diſorders which are the general effects of intemperance in the human body. As hay is ſo material an article in a horſe's diet, great care ſhould be taken to procure the beſt: when it is not extraordinary, the durſt ſhould be well ſhook out before it is put in the rack; for ſuch hay is very apt to breed vermin.

Bran ſcalded is a kind of panada to a ſick horſe: but nothing is worſe than a too frequent uſe of it, either dry or ſcalded; for it relaxes and weakens the bowels too much. Oats, well ripened, make a more hearty and durable diet than barley, and are much better ſuited to the conſtitutions of Britiſh horſes. The ſalt marſhes are good paſture for horſes who have been ſurfeited, and indeed for many other diſorders: they purge more by dung and urine than any other paſture, and make afterwards a firmer fleſh; their water is for the moſt part blackiſh, and of courſe, as well as the graſs, ſaturated with ſalts from the ſea water. A ſummer's graſs is often neceſſary; more particularly to horſes who have been worked hard, and have ſtiff limbs, ſwelled legs, or windgalls. Horſes whoſe feet have been impaired by quittors, bad ſhoeing, or any other accidents, are alſo beſt repaired at graſs. Thoſe lameneſſes particularly require turning out to graſs, where the muſcles or tendons are contracted or ſhrunk; for by the continual gentle exerciſe in the field, with the aſſiſtance of a pattin ſhoe on the oppoſite foot, the ſhortened limb is kept on the ſtretch, the waſted parts are reſtored to their ordinary dimenſions, and the limb again recovers its uſual tone and ſtrength.

Horſes may be kept abroad all the year, where they have a proper ſtable or ſhed to ſhelter them from the weather, and hay at all times to come to. So treated, they are ſeldom ſick; their limbs are always clean and dry; and, with the allowance of corn, will hunt, and do more buſineſs than horſes kept conſtantly within doors. When horſes loſe their fleſh much in ſoiling, they ſhould in time be taken to a more ſolid diet: for it is not in ſoiling as in grazing; where, though a horſe loſes his fleſh at firſt, yet, after the graſs has purged him, he ſoon grows fat. Young horſes who have not done growing, muſt be indulged more in their feeding, than thoſe come to their maturity; but if their exerciſe is ſo little as to make it neceſſary to abridge their allowance of hay, a little freſh ſtraw ſhould conſtantly be put in their racks, to prevent their nibbling the manger, and turning cribbiters; they ſhould alſo be ſometimes ſtrapped back in order to cure them of this habit. It is obvious to every one, what care ſhould be taken of a horſe after violent exerciſe, that he cool not too faſt, and drink no cold water, &c.

When a horſe comes out of a dealer's hands, his cloathing muſt be abated by degrees, and care taken to put him in a moderately warm ſtable; otherwiſe the ſudden tranſition would be attended with the worſt conſequences.

Horſes who ſtand much in ſtable, and are well fed, require bleeding now and then; eſpecially when their eyes look heavy, dull, red, and inflamed; as alſo, when they feel hotter than uſual. Young horſes ſhould be bled when they are ſhedding the teeth, as it takes off thoſe feeveriſh heats they are then ſubject to. But the caſes that chiefly require bleeding, are colds, fevers of moſt kinds, falls, bruiſes, hurts of the eyes, ſtrains, and all inflammatory diſorders, &c. It is right to bleed a horſe, when he begins to grow fleſhy at graſs, or at any other time when he looks heavy: and it is generally proper to bleed before purging. Let your horſe always be bled by meaſure, that you may know what quantity you take away: two quarts are always enough at one time; when you repeat it, allow for the diſorder and the horſe's conſtitution. Let the blood, when cold, be carefully examined, both as to colour and conſiſtence, whether black, florid, ſizey, &c.

Purging is often neceſſary in groſs full horſes, in ſome diſorders of the ſtomach, liver, &c. but ſhould be directed with caution. Before a purge is given to any horſe, it is neceſſary ſome preparation ſhould be made for it, in order to render the operation more ſafe and efficacious: thus a horſe that is full of fleſh ſhould firſt be bled, and at the ſame time have his diet lowered for a week, eſpecially thoſe that have been pampered for ſale; ſeveral maſhes of ſcalded bran ſhould alſo previouſly be given, in order to open the bowels, and unload them of any indurated excrement, which ſometimes proves an obſtacle to the working of the phyſic, by creating great ſickneſs and griping. Let it be remembered, that a horſe is purged with difficulty; that the phyſic generally lies 24 hours in the guts before it works; and, that the tract of bowels it has to paſs through, is above 30 yards; and lying horizontally; conſequently reſinous and other improper drugs may, and often do, by their violent irritations, occaſion exceſſive gripings and cold ſweats, ſhave off the very mucus or lining of the guts, and bring on inflammations, which often terminate in mortifications, and death. It is remarkable too, that the ſtomach and guts of a horſe are but thin, compared to ſome other animals of the ſame bulk, and therefore muſt be more liable to inflammation and irritation. Horſes kept much in the ſtable, who have not the proper benefit of air and exerciſe in proportion to their food, ſhould in ſpring have a mild purge or two after a previous preparation by bleeding, lowering their diet, and ſcalded maſhes. Horſes of a watery conſtitution, who are ſubject to ſwelled legs, that run a ſharp briny ichor, cannot have the cauſes removed any way ſo effectually as by purging. The firſt purge you give to a horſe ſhould be mild, in order to know his conſtitution. It is a miſtaken notion, that if a proper prepared purge does not work to expectation, the horſe will be injured by it, for though it does not paſs by ſtool, its operation may be more efficacious as an alterative to purify the blood, and it may paſs by urine or other ſecretions. Purges ſhould be given early in the morning upon an empty ſtomach: about three or four hours after the horſe has taken it, he ſhould have a feed of ſcalded bran; and a lock or two of hay may then be put into his rack. The ſame day give him two more maſhes; but ſhould he refuſe warm meat, he may be allowed raw bran. All his water ſhould be milk warm, and have a handful of bran ſqueezed in it; but if he refuſes to drink warm water, give it him without bran. During the working, a horſe ſhould drink plentifully; but, if he will not drink warm water, he muſt be indulged with cold, rather than not drink at all.

We ſhall here inſert ſome general forms of purges.

Take ſocotorine aloes ten drams, jalap and ſalt of tartar each two drams, grated ginger one dram, oil of cloves 30 drops; make them into a ball with ſyrup of buckthorn.

Or the following, which has an eſtabliſhed character among ſportſmen.

Take aloes from ten drams to an ounce and an half, myrrh and ginger powdered each half an ounce, ſaffron and oil of aniſeed each half a dram.

Mr. Gibſon recommends the following:

Take ſocotorine aloes ten drams, myrrh finely powdered half an ounce, ſaffron and freſh jalap in powder of each a dram; make them into a ſtiff ball with ſyrup of roſes, then add a ſmall ſpoonful of rectified oil of amber.

The ſocotorine aloes ſhould always be preferred to the Barbadoes or plantation aloes: though the latter may be given to robuſt ſtrong horſes; but even then ſhould always be prepared with the ſalt or cream of tartar, which by opening its parts, prevents its adheſion to the coats of the ſtomach and bowels; from whence horrid gripings, and even death itſelf has often enſued. This caution is well worth remarking, as many a horſe hath fallen a ſacrifice to the neglect of it.

The following purging drink may be given with the utmoſt ſafety; it may be quickened, or made ſtronger by adding an ounce more ſenna, or two drams of jalap.

Take ſenna two ounces; infuſe it in a pint of boiling water two hours, with three drams of ſalt of tartar; pour off, and diſſolve in it four ounces of Glauber's ſalts, and two or three of cream of tartar.

This laſt phyſic is cooling, eaſy, and quick in its operation; and greatly preferable in all inflammatory caſes to any other purge, as it paſſes into the blood, and operates alſo by urine. When horſes loſe their appetites after purging, it is neceſſary to give them a warm ſtomach drink made of an infuſion of camomile flowers, anniſeeds, and ſaffron: or the cordial ball may be given for that purpoſe. Should the purging continue too long, give an ounce of diaſcordium in an Engliſh pint of Port-wine; and repeat it once in 12 hours if the purging continues. Plenty of gum-arabic water ſhould alſo be given; and in caſe of violent gripes, fat broth glyſters, or tripe liquor, ſhould be often thrown up, with 100 drops of laudanum in each.

The arabic ſolution may be thus prepared:

Take of gum arabic and tragacanth of each four ounces, juniper berries and carraway ſeeds of each an ounce, cloves bruiſed half an ounce; ſimmer gently in a gallon of water, till the gums are diſſolved: give a quart at a time in half a pail of water; but if he will not take it freely this way, give it him often in a horn.

When a purge does not work, but makes the horſe ſwell, and refuſe his food and water, which is ſometimes the effect of bad drugs or catching cold, warm diuretics are the only remedy; of which the following are recommended:

Take a pint of white wine, nitre one ounce: mix with it a dram of camphire, diſſolved in a little rectified ſpirit of wine; then add two drams of oil of juniper, and the ſame quantity of unrectified oil of juniper, and the ſame quantity of unrectified oil of amber, and four ounces of honey or ſyrup of marſhmallows.

When a horſe ſwells with much phyſic, do not ſuffer him to be rode about till he has ſome vent; but rather lead him gently in hand till ſome evacuation is obtained. As it is obſerved, that horſes more willingly take ſweet and palatable things than thoſe that are bitter and of an ill taſte, care ſhould be taken that the latter be given in balls, and that their drinks be always contrived to be as little nauſeous as poſſible, and ſweetened either with honey or liquorice. Thoſe that are prepared with groſs powders are by no means ſo agreeable to a horſe, as thoſe made by infuſion; as the former often clam the mouth, irritate the membranes about the palate and throat, and frequently occaſion the cough they are intended to prevent. Balls ſhould be of an oval ſhape, and not exceed the ſize of a pullet's egg: when the doſe is larger, it ſhould be divided into two; and they ſhould be dipt in oil, to make them ſlip down the eaſier. As we have given ſome general forms of purges, we ſhall obſerve the ſame rule in regard to glyſters, with ſome few cautions and remarks. Some writers on this ſubject recommend, previous to the adminiſtration of glyſters in coſtive diſorders, the paſſing of a ſmall hand well oiled up the horſes fundament, in order to bring out any hardened dung, which otherwiſe would be an obſtacle to the glyſter's paſſage. But we do not approve of this practice. A bag and pipe of a proper form is to be preferred to a ſyringe, which throws up the glyſter with ſo much force, that it often ſurpriſes a horſe, and makes him reject it as faſt as it goes in; whereas the liquor, when preſſed gently from the bag, gives him no ſurpriſe or uneaſineſs, but paſſes eaſily up into the bowels, where it will ſometimes remain a long time, and be extremely uſeful, by cooling and relaxing them; and will ſometimes incorporate ſo with the dung, as not eaſily to be diſtinguiſhed from the other contents of the guts.

Purging Glyſter. — TAKE two or three handfuls of marſhmallows, ſenna one ounce, bitter apple half an ounce, bay berries and anniſeeds bruiſed each an ounce, ſalt of tartar half an ounce; boil a quarter of an hour in three quarts of water; pour off, and add four ounces of ſyrup of buckthorn, and half a pint of oil.

This glyſter will purge a horſe pretty briſkly; and may be given ſucceſsfully, when an immediate diſcharge is wanting; eſpecially in ſome fevers with inflamed lungs, or other diſorders, which require ſpeedy relief.

Rowelling. — There ſeems to be no remedy ſo much made uſe of, and ſo little underſtood by farriers in general, as rowels; for which reaſon we ſhall endeavour to ſet the whole affair in a clearer light than hitherto it has appeared in. We ſhall begin, then, by deſcribing rowelling; which is an artificial vent made between the ſkin and fleſh, in order to unload and empty the veſſels in general, and thereby relieve particular parts when too much oppreſſed by a fulneſs or redundancy. The general and abſurd reaſoning of farriers on the effects and uſe of rowelling, in ſome meaſure makes theſe remarks the more neceſſary, as it is too notorious how impertinently they talk on this ſubject: for in ſhort, with them, a rowel is to draw off all the bad and corrupt humours from the blood by a ſort of magic. It is neceſſary to obſerve, that the matter generally diſcharged by a rowel, is nothing more than an ouzing from the extremities of the veſſels divided in the making of it; in fact, then, it is blood, which loſes its colour, by being ſhed out of the veſſels, by the warmth of the part, and by its confinement. If this is granted, it will evidently appear, that the good effects enſuing from this operation muſt be owing to a gradual depletion or emptying of the veſſels in general; by which means the ſurcharge or load on a particular part is taken off and removed, and impurities or bad juices (generally called humours) run off with the good in proportion to their quantity in the blood. Thus, to lean hide-bound horſes, and thoſe of a dry hot conſtitution, the diſcharge, by depriving the conſtitution of ſo much blood and fluids, is daily exhauſting the ſtrength of the animal; and may be productive of bad conſequences, by defrauding the conſtitution of a neceſſary fluid. But in diſorders from fulneſs, attended with acrimony or ſharpneſs of the juices, and with defluxions on the eyes, lungs, or any part of conſequence; the gradual diſcharge, brought on by theſe means, will contribute to leſſen the fulneſs on the parts affected, and give the veſſels an opportunity of recovering their tone, while evacuating and alterative medicines are doing their office. It may be neceſſary, however, to obſerve, that there is a wonderful communication between the veſſels of the cellular membrane under the ſkin, which remarkably appears, by inflating thoſe of ſheep, calves, &c. by the butchers: hence, probably, it is, that ſome diſorders of this integument are ſo apparently relieved by iſſues, or rowels, without our having any recourſe to that general depletion of the veſſels, we have juſt obſerved, to account for it; and hence, alſo, may be deduced their utility, ſometimes in draining off any extravaſated fluids which may lodge between the interſtices of the muſcles, after violent ſtrains of the ſhoulder; alſo in diſcharging ſuch vicious or ſharp fluids as are thrown on the membranes, and occaſion thoſe flying pains and lameneſſes which we find are often removed by this local remedy.

With reſpect to the diſeaſes incident to the horſe, by claſſing together thoſe which bear a reſemblance to each other, and of courſe require a ſimilar mode of treatment, we ſhall preſerve a due order of arrangement, as well as render the ſubject more intelligible to the reader.

CLASS I.

SECT. I. *Strains.*

All violent ſtrains of the ligaments, which connect the bones together, eſpecially thoſe of the thigh, require time, and turning out to graſs, to a perfect recovery. External applications can avail but little here, the parts affected lying too deep, and ſo ſurrounded with muſcles that medicine cannot penetrate to them. The ſooner, in theſe caſes, a horſe is turned out to graſs, the better; as the gentle motion in the field will prevent the ligaments and joint-oil from thickening, and of courſe the joint itſelf from growing ſtiff. When a horſe's ſhoulder is overſtrained, he does not put out that leg as the other; but, to prevent pain, ſets the ſound foot hardily on the ground to ſave the other; even though he be turned ſhort on the lame ſide, which motion tries him the moſt of any. When trotted in hand, inſtead of putting his leg forward in a right line, he forms a circle with the lame leg; and when he ſtands in the ſtable, that leg is advanced before the other. In order to cure this lameneſs, firſt bleed him; and let the whole ſhoulder be well bathed three times a-day with hot verjuice or vinegar, in which may be diſſolved a piece of ſoap; but if the lameneſs continues without ſwelling, or inflammation, after reſting two or three days, let the muſcles be well rubbed for a conſiderable time, to make them penetrate, with good opodeldoch, or either of the following mixture:

TAKE camphorated ſpirit of wine, two ounces; oil of turpentine, one ounce; this proportion will prevent the hair coming off. Or, Take the beſt vinegar, half a pint; ſpirit of vitriol, and camphorated ſpirit of wine, of each two ounces.

When the ſhoulder is very much ſwelled, it ſhould be fomented with woollen cloths (large enough to cover the whole) wrung out of hot verjuice and ſpirit of wine; or a fomentation prepared with a ſtrong decoction of wormwood, bay-leaves, and roſemary, to a quart of which may be added half a pint of ſpirit of wine. Where poultices can be applied, they are at firſt undoubtedly very effectual, after bathing with hot vinegar or verjuice; and are to be preferred greatly to cold charges, which, by drying ſo ſoon on the part, keep it ſtiff and uneaſy: let them be prepared with oatmeal, rye flour, or bran boiled up in vinegar, ſtrong beer or red wine lees, with lard enough to prevent their growing ſtiff; and when by theſe means the inflammation and ſwelling are brought down, bathe the part twice a-day with either of the above mixtures, opodeldoch, or camphorated ſpirit of wine; and roll the part three or four inches, both above and below, with a ſtrong linen roller, of about two fingers width; which contributes not a little to the recovery, by bracing up the relaxed tendon; and perhaps is more to be depended on than the applications themſelves. Strains of the back ſinews are very common; and are eaſily diſcovered by the ſwelling, which extends ſometimes from the back-ſide of the knee down to the heel, but for the moſt part the horſe ſets that foot before the other. The tendon ſhould be well bathed three or four times a-day with hot vinegar; and if much ſwelled, apply the poultices above recommended; and when the ſwelling is down, bathe with the mixtures above, or with camphorated ſpirit of wine and oil of amber, in which is diſſolved as much camphor as the ſpirits will take up; and roll up the tendon with a proper bandage, or laced ſtocking; which laſt, properly fitted to the limb, might be wore to great advantage, not only in theſe ſort of injuries, but in moſt others, where there is a diſpoſition to the greaſe, or other ſwelling of the limbs, from weak and relaxed fibres. Curriers ſhavings wetted with vinegar have been found uſeful for this purpoſe; as have alſo tar and ſpirit of wine; but where the tendons have ſuffered by repeated injuries of this kind, the caſe will demand bliſtering, and proper reſt. Strains of the knees and paſterns ariſe frequently from kicks or blows: if they are much ſwelled, apply firſt the poultices; and when the ſwelling is abated, bathe with the above. Many writers recommend firing in this caſe as well as others. But it is a practice we can by no means approve, as we heartily concur with Mr. Taplin in opinion, that this truly diſagreeable and diſtreſſing alternative ſhould never be adopted, till all the more gentle applications have repeatedly failed in effect.

SECT. II. *Wind-galls.*

A wind-gall is a flatulent ſwelling, which yields to the preſſure of the finger, and recovers its ſhape on the removal thereof: the tumour is viſible to the eye, and often ſeated on both ſides of the back ſinew, above the fetlocks, on the fore-legs, but moſt frequently on the hind-legs; though they are met with in various parts of the body, wherever membranes can be ſo ſeparated, that a quantity of air and ſeroſities may be included within their duplicatures. When they appear near the joints and tendons, they are generally cauſed by ſtrains, or bruiſes on the ſinews, or the ſheath that covers them; which, by being overſtretched, have ſome of their fibres ruptured; whence probably may ouze out that fluid which is commonly found with the included air; though, where theſe ſwellings ſhew themſelves in the interſtices of large muſcles, which appear blown up like bladders, air alone is the chief fluid; and theſe may ſafely be opened, and treated as a common wound. On the firſt appearance of wind-galls, their cure ſhould be attempted by reſtringents and bandage; for which purpoſe, let the ſwelling be bathed twice a-day with vinegar, or verjuice alone; or let the part be fomented with a decoction of oak-bark, pomegranate, and alum boiled in verjuice, binding over it, with a roller, a woollen cloth ſoaked in the ſame. Some, for this purpoſe, uſe red-wine lees, others curriers ſhavings wetted with the ſame, or vinegar, bracing the part up with a firm bandage. If this method, after a proper trial, ſhould not be found to ſucceed, authors have adviſed the ſwelling to be pierced with an awl, or opened with a knife: but mild bliſtering has in general the preference given to theſe methods; the included fluids being drawn off, the impacted air diſperſed, and the tumour gradually diminiſhed.

SECT. III. *Spavins.*

Theſe are of two ſpecies, denominated the blood and the bone ſpavin. A blood-ſpavin is a ſwelling and dilatation of the vein that runs along the inſide of the hough, forming a little ſoft ſwelling in the hollow part, and is often attended with a weakneſs and lameneſs of the hough. The cure ſhould be firſt attempted with the reſtringents and bandage above recommended, which will contribute greatly to ſtrengthen all weakneſſes of the joints, and frequently will remove this diſorder if early applied: but if by theſe means the vein is not reduced to its uſual dimenſions, the ſkin ſhould be opened, and the vein tied with a crooked needle and wax-thread paſſed underneath it, both above and below the ſwelling, and the turgid part ſuffered to digeſt away with the ligatures: for this purpoſe, the wound may be daily dreſſed with turpentine, honey, and ſpirit of wine, incorporated together.

Without entering into the cauſe of the bone ſpavin, which is a bony excreſcence, or hard ſwelling, growing on the inſide of the hough of a horſe's leg, we ſhall content ourſelves with deſcribing the different kinds thereof by their ſymptoms, and then enter on their cure. If a fulneſs on the fore-part of the hock comes upon hard riding, or any other violence, which threatens a ſpavin; in that caſe, ſuch coolers and repellers are proper, as are recommended in ſtrains and bruiſes. Thoſe happening to colts and young horſes are generally ſuperficial, and require only the milder applications; for it is better to wear them down by degrees, than to remove them at once by ſevere means. Various are the preſcriptions for the bliſtering ointment; but the following, on proper experience, ſtands well recommended by Mr. Gibſon.

Take nerve and marſh-mallow ointment, of each two ounces; quickſilver, one ounce, thoroughly broke, with an ounce of Venice turpentine; Spaniſh flies powdered, a dram and a half; ſublimate, one dram; oil of origanum, two drams.

The hair is to be cut as cloſe as poſſible, and then the ointment applied pretty thick over the part; this ſhould be done in the morning, and the horſe kept tied up all day without any litter till night; when he may be untied, in order to lie down; and a pitch or any ſticking plaſter may be laid over it, and bound on with a broad tape or bandage to keep all cloſe. After the bliſter has done running, and the ſcabs begin to dry and peel off, it may be applied a ſecond time, in the ſame manner as before; this ſecond application generally taking greater effect than the firſt, and in colts and young horſes makes a perfect cure. When the ſpavin has been of long ſtanding, it will require to be renewed, perhaps, five or ſix times: but after the ſecond application, a greater diſtance of time muſt be allowed, otherwiſe it might leave a ſcar, or cauſe a baldneſs; to prevent which, once a-fortnight or three weeks is often enough: and it may in this manner be continued ſix or ſeven times, without the leaſt blemiſh, and will generally be attended with ſucceſs. But the ſpavins that put out on older or full-aged horſes are apt to be more obſtinate, as being ſeated more inward; and when they run among the ſinuoſities of the joint, they are for the moſt part incurable, as they then lie out of the reach of applications, and are arrived to a degree of impenetrable hardneſs.

SECT. IV. *Splents.*

Theſe are hard excreſcences that grow on the ſhank bone, and are of various ſhapes and ſizes. Some horſes are more ſubject to ſplents than others; but young horſes are moſt liable to theſe infirmities, which often wear off and diſappear of themſelves. Few horſes put out ſplents after they are ſeven or eight years old, unleſs they meet with blows or accidents. A ſplent that ariſes in the middle of the ſhank bone is not dangerous; but thoſe that ariſe on the back part of this bone, when they grow large and preſs againſt the back ſinew, always cauſe lameneſs or ſtiffneſs, by rubbing againſt it; the others, except they are ſituated near the joints, ſeldom occaſion lameneſs. As to the cure of ſplents, the beſt way is not to meddle with them, unleſs they are ſo large as to disfigure a horſe, or are ſo ſituated as to endanger his going lame. Splents in their infancy, and on their firſt appearance, ſhould be well bathed with vinegar, or old verjuice; which, by ſtrengthening the fibres, often put a ſtop to their growth; for the membrane covering the bone, and not the bone itſelf, is here thickened; and in ſome conſtitutions purging, and afterwards diuretic drinks, will be a great means to remove the humidity and moiſture about the limbs, which is what often gives riſe to ſuch excreſcences. Various are the remedies preſcribed for this diſorder; the uſual way is to rub the ſplent with a round ſtick or the handle of a hammer, till it is almoſt raw, and then touch it with oil of origanum. Others lay on a pitch plaſter, with a little ſublimate, or arſenic, to deſtroy the ſubſtance; ſome uſe oil of vitriol; ſome tincture of cantharides: but Taplin objects to all theſe methods, and obſerves that the only expectation of cure without anxiety and difficulty, is to be careful in obſerving ſuch appearances in their early ſtate; and then ſeeing that friction is uſed twice a day for a conſiderable time, with the utmoſt force of the hand, with a portion of the following liniment, leaving a pledget of tow wet with the ſame, bound on pretty firm, with two yards of wide tape as a roller:

Take camphorated ſpirits of wine and ſpirits of turpentine, of each two ounces (a quarter of a pound) mixt together. Or, oil of origanum and ſpirits of turpentine, each half an ounce; camphorated ſpirits of wine, two ounces.

If theſe repellants fail, he recommends the following method: Procure two ounces of the ſtrongeſt mercurial ointment, and let the ſize of a hazel nut be rubbed in upon the part affected, every night and morning till the whole is conſumed, uſing the roller each night, and taking it off in the morning. He adds, if this does not ſucceed, the beſt and moſt ſpeedy method will be immediate extirpation, by making a longitudinal inciſion (without *bruiſing, hammering*, &c. as recommended by ſome) through the integuments, diſſecting and extracting the ſubſtance, compleating the cure by taking up a couple of ſtitches, and treating it as a ſuperficial wound. The ſame author further obſerves, that Bartlet's ſyſtem of purging balls and diuretic drinks, may be adopted by thoſe whoſe credulity can conceive that a courſe of purgatives and diuretics will contribute to the removal of corns and warts from the feet and hands of the human ſpecies.

CLASS II.

SECT. V. *Greaſe.*

In order to treat this diſorder with ſome propriety, we ſhall conſider it as ariſing from two different cauſes: a fault or relaxation in the veſſels, or a bad diſpoſition in the blood and juices. We muſt here obſerve, that the blood and juices or humours, (for there are always ſome in the beſt ſtate of blood) are brought to the extreme parts by the arteries, and returned by the veins; in which latter, the blood is to riſe in perpendicular columns, to return the circulating fluids from the extremities; hence ſwellings in the legs of horſes may eaſily be accounted for, from a partial ſtagnation of the blood and juices in the finer veſſels, where the circulation is moſt languid; and eſpecially when there is want of due exerciſe, and a proper muſcular compreſſion on the veſſels, to puſh forward the returning blood, and propel the inert and half-ſtagnating fluids through their veſſels; in ſhort, the blood in ſuch caſes cannot ſo readily aſcend as deſcend, or a greater quantity is brought by the arteries than can be returned by the veins. The greaſe then, conſidered in this light, muſt be treated as a local complaint, where the parts affected are alone concerned, the blood and juices being yet untainted, and in good condition: or as a diſorder where they are both complicated; but when it is an attendant on ſome other diſtemper, as the farcy, yellows, dropſy, &c. ſuch diſeaſes muſt firſt be cured before the greaſe can be removed. In the former caſe, moderate exerciſe, proper dreſſing, cleanlineſs, and external application, will anſwer the purpoſe; in the latter, internals muſt be called in to our aſſiſtance, with proper evacuations. When a horſe's heels are firſt obſerved to ſwell in the ſtable, and ſubſide or go down on exerciſe; let care be taken to waſh them very clean every time he comes in, with ſoap-ſuds, chamber-ley, or vinegar and water; which, with proper rubbing, will frequently prevent, or remove, this complaint; or let them be well bathed twice a-day with old verjuice, or the following mixture, which will brace up the relaxed veſſels; and if rags dipped in the ſame are rolled on, with a proper bandage, for a few days, it is moſt likely the ſwellings will ſoon be removed by this method only, as the bandage will ſupport the veſſels till they have recovered their tone. To anſwer this end, alſo, a laced ſtocking made of ſtrong canvas or coarſe cloth, neatly fitted to the part, would be found extremely ſerviceable, and might eaſily be contrived by an ingenious mechanic.

Take rectified ſpirit of wine, four ounces; diſſolve in it half an ounce of camphor; to which add wine-vinegar, or old verjuice, ſix ounces; white vitriol, diſſolved in a gill of water, one ounce; mix together, and ſhake the phial when uſed.

But if cracks or ſcratches are obſerved, which ouze and run, let the hair be clipped away, as well to prevent a lodgment (which becomes ſtinking and offenſive by its ſtay), as to give room for waſhing out dirt, or gravel, which, if ſuffered to remain there, would greatly aggravate the diſorder. When this is the caſe, or the heels are full of hard ſcabs, it is neceſſary to begin the cure with poultices, made either of boiled turnips and lard, with a handfull of linſeed powdered; or oatmeal and rye-flour, with a little common turpentine and hogs lard, boiled up with ſtrong-beer grounds or red-wine lees. The digeſtive ointment being applied to the ſores for two or three days, with either of theſe poultices over it, will, by ſoftening them, promote a diſcharge, unload the veſſels, and take down the ſwellings; when they may be dried up with the following:

Take white vitriol and burnt alum, of each two ounces: Ægyptiacum, one ounce; lime-water, a quart or three pints: waſh the ſores with a ſponge dipped in this, three times a-day; and apply the common white ointment ſpread on tow, to an ounce of which may be added two drams of ſugar of lead.

We would recommend the nitre-balls given to the quantity of two ounces a-day, for a month or ſix weeks, mixed up with honey, or in his feeds; take the following alſo for that purpoſe.

Yellow roſin, four ounces; ſalt of tartar, and ſal prunella, of each two ounces; Venice ſoap, half a pound; oil of juniper, half an ounce; make into balls of two ounce weight, and give one every morning.

If the diuretic balls ſhould not ſucceed, they muſt be changed for the antimonial and mercurial alteratives, but turning a horſe out in a field, where he has a hovel or ſhed to run to at pleaſure, would greatly contribute to quicken the cure, and indeed would in general effect it alone; but if this cannot be complied with, let him be turned out in the day-time. If the horſe is not turned out, a large and convenient ſtall is neceſſary, with good dreſſing and care.

SECT. VI. *Running Thruſhes.*

A Running Thruſh (or Fruſh), is a diſcharge of a fetid, and ſometimes ichorous, matter, from the cleft in the middle of the frog, affecting one, frequently both, and in ſome caſes all the four feet. But, generally, the fore-feet are moſt ſubject to this diſeaſe. To explain this more particularly, there is, in the middle of the frog, a cleft or opening, by which the heels in a natural ſtate have a ſmall degree of contraction and expanſion, eſpecially when the horſe treads or preſſes his heel upon the ground, the frog then expands; when, therefore, a horſe is ſhoed with concave or hollow ſhoes, the heels are deprived of that power of expanſion, being conſtantly confined in a contracted ſtate by the reſiſtance from the outer edges of the concave ſhoe, by which the frog is preſſed or ſqueezed on both ſides, by the cruſt of the heels being brought nearer to or almoſt into contact with one another. Hence pain, inflammation, an obſtruction of the blood, &c. (in the fleſhy ſubſtance of the frog), and of courſe that waſting and rottenneſs of its external covering, which, falling off in pieces, leaves the quick almoſt bare: the new frog, growing in detached pieces, never acquires the ſolidity of the former; and hence that rawneſs and tenderneſs which ever afterwards remain, and that extreme ſenſibility of pain when any hard ſubſtance touches that part of the foot, and of courſe ſubjects the horſe to frequent lameneſs. But in thoſe hoofs which are wide and open at the heels, where the complaint is recent, one or both the fore-feet only being affected, and where there is reaſon to ſuſpect that it proceeds from the uſe of concave or hollow ſhoes, or keeping the hoofs too hot, dry, and hard, it may be compleated with eaſe and ſafety, by laying aſide the uſe of concave ſhoes, waſhing the frogs clean after exerciſe, and dreſſing them with Mel Egyptiacum, made as follows:

Mel Egyptiacum. Verdigris in fine powder, two ounces; honey ſix ounces; vinegar, four ounces; boil them on a gentle fire till they have acquired a reddiſh colour.

But at the ſame time, recourſe muſt be had to internal remedies by way of revulſion, as purging or diuretic medicines, bleeding being firſt premiſed: if the former is made choice of, twice or thrice will be ſufficient, repeated at proper intervals; but if the latter which ſeems preferable, they may be continued for ſometime with great ſafety, without loſing one day's work of the horſe. In horſes of a groſs habit of body, eſpecially the heavy draught kind, running thruſhes ſometimes degenerate into what is commonly called a canker. In this caſe, the horny ſubſtance of the frog is ſoon thrown off; the fleſhy parts grow to an immoderate ſize, the luxuriant ſubſtance or ſpongy fleſh having a great number of papillæ, or tubercles of a pale red, and ſometimes variegated and tinged with blood; attended with a copious diſcharge of a thin ichorous fetid humour, having a moſt offenſive ſmell. If its progreſs be not ſpeedily ſtopt, the fleſhy ſole, from its vicinity, becomes likewiſe affected; the horny ſide rots, decays, and falls off; the whole foot turns into a kind of quag or bog, (in warm weather full of maggots, which it is almoſt impoſſible to prevent, even with the moſt corroſive dreſſings); the tendons become likewiſe affected, the bones carious, the hoof falls off, and the horſe is rendered uſeleſs. As to external applications, the firſt thing neceſſary to be done, is to pare down the cruſt till it is lower than the fungus, or growth of the canker, and to remove any hard pieces of the hoof or ſole wherever it preſſes upon the tender parts; the circular part of the cruſt ſhould be ſurrounded and kept ſoft with an emollient poultice. For dreſſings, the mildeſt eſcharotic powders may be firſt tried, as the following:

Take burnt alum powdered, two ounces; blue vitriol powdered one ounce.

But, when it degenerates into the laſt ſpecies mentioned above, affecting the fleſhy ſole, &c. the ſtrongeſt corroſive applications will then be neceſſary, and ſometimes hardly ſufficient to keep down the luxuriancy of the fungus. The cauſtic oils are found preferable, as ol. vitriol. aqua fortis, butter of antimony: either of theſe may be applied once every day; otherwiſe, if neglected dreſſing too long, or to every other day, which is the common practice, the great humidity and moiſture iſſuing from the fungus ſo weaken the force of the ſtrongeſt oils, that they have little or no effect: when theſe ſharp dreſſings ſeem to gain upon the canker, it may be dreſſed with equal parts of red precipitate and burnt alum pounded and mixed together, till ſuch time as the new ſole begins to grow; the purging or diuretic medicines being given at proper intervals till the cure is compleated.

SECT. VII. *Sand-cracks.*

As ſand and gravel are eaſily admitted into chinks, or cracks; where, being accumulated and pent up, they irritate and inflame the parts, whereby matter is formed underneath the hoof, which cauſes lameneſs, and which not unfrequently breaks out at the coronet, producing the moſt inveterate ulcers, which become extremely difficult to heal, on account of the ſinus or fiſtula branching out in different directions underneath the hoof. Therefore, horſes with this defect ſhould be carefully obſerved, and when the thick hardened edges of the chinks or cracks grow too high, by which it is ſo much the deeper, and, of courſe, lodges the greater quantity of ſand, &c. theſe edges ſhould be raſped, or pared with a crooked knife, till the ſeam diſappears. But wherever there remains a blackneſs, or appearance of gravel, that part muſt be traced farther; always obſerving, if poſſible, to avoid drawing blood. The chink or crack thus made ſmooth and equal, no ſand or gravel can lodge in it; and, as the parts will be tender, it will be neceſſary to apply an emollient poultice for ſome days, till the tenderneſs wear off. If the inflammation has been great, and matter formed in the crack, or the parts wounded by the knife in cutting its hardened edges, proud fleſh may riſe and jet out. In this caſe, the hard parts of the hoof near it are to be removed, a digeſtive poultice applied, and, when the inflammation is abated, the proud fleſh may be touched with the following corroſive powder:

Take blue vitriol burnt, two drams; corroſive ſublimate, one dram; rubbed into powder.

Sand cracks are generally the effect of flight or ſuperficial wounds upon the coronet, and grow gradually downwards towards the baſis of the hoof, and at laſt are cut or raſped off in the ſhoeing: when they occaſion lameneſs from lodging ſand or gravel, they muſt be treated in the manner already mentioned.

SECT. VIII. *Surfeits.*

Surfeits ariſe from various cauſes; but are commonly the effects of ſome diſeaſes not attended to, or that have been ill cured. Taplin, with apparent reaſon, attributes ſurfeits in a great meaſure to ſuffering horſes to drink immoderately of cold water when in a violent perſpiration, and the blood of courſe in the higheſt degree of circulation. A horſe is ſaid to be ſurfeited, when his coat ſtares, and looks ruſty and dirty, though proper means have not been wanting to keep him clean. The ſkin is full of ſcales and dander, and lies thick and meally among the hair, and is conſtantly ſupplied with a freſh ſucceſſion of the ſame, for want of due tranſpiration. Some horſes have hurdles of various ſizes, like peas or tares; ſome have dry fixed ſcabs all over their limbs and bodies; others a moiſture, attended with heat and inflammation; the humours being ſo ſharp, and violently itching, that the horſes rub ſo inceſſantly, as to make themſelves raw. Some have no eruptions at all; but an unwholeſome look, and are dull, ſluggiſh, and lazy: ſome appear only lean and hide bound; others have flying pains and lameneſs, reſembling a rheumatiſm: ſo that in the ſurfeits of horſes, we have almoſt all the different ſpecies of the ſcurvy and other chronical diſtempers. The following method is uſually attended with ſucceſs in the dry ſpecies. Firſt take away three or four pounds of blood, and then give the following mild purge, which will work as an alterative, and ſhould be repeated once a-week or ten days for ſome time.

Take ſocotorine aloes ſix drams or one ounce, gum guaiacum half an ounce, diaphoretic antimony and powder of myrrh, of each two drams; make into a ball with ſyrup of buckthorn.

In the intermediate days, an ounce of the following powder ſhould be given, morning and evening, in his feeds:

Take native cinnabar, or cinnabar of antimony, finely powdered, half a pound; crude antimony, in fine powder, four ounces; make into 16 doſes for eight days.

This medicine muſt be repeated till the horſe coats well, and all the ſymptoms of ſurfeit diſappear. The wet ſurfeit, which is no more than a moiſt running ſcurvy, appears on different parts of the body of a horſe, attended ſometimes with great heat and inflammation; the neck oftentimes ſwells ſo in one night's time, that great quantities of a hot briny humour iſſue forth, which, if not allayed, will be apt to collect on the poll or withers, and produce the poll evil or fiſtula. This diſeaſe alſo frequently attacks the limbs, where it proves obſtinate and hard to cure, and in ſome horſes ſhows itſelf ſpring and fall. In this caſe bleed plentifully, avoid externally all repellers, and give cooling phyſic twice a week; as, four ounces of lenitive electuary, with the ſame quantity of cream of tartar; or the latter, with four ounces of Glauber's ſalts, quickened, if thought proper, with two or three drams of powder of jalap, diſſolved in water gruel, and given in a morning faſting. After three or four of theſe purges, two ounces of nitre made into a ball with honey may be given every morning for a fortnight; and if attended with ſucceſs, repeat it for a fortnight longer. The powders above mentioned may be alſo given with the horſe's corn; or a ſtrong decoction of guaiacum ſhavings or logwood may be given alone to the quantity of two quarts a-day. Theſe, and indeed all alterative medicines, muſt be continued for a long time where the diſorder proves obſtinate. The diet ſhould be cool and opening, as ſcalded bran or barley; and if the horſe is hide bound, an ounce of fenugreek ſeeds ſhould be given in his feeds for a month or longer; and, as this diſorder often proceeds from worms, give the mercurial phyſic too, and afterwards the cinnabar powders, as before directed. But as in general it is not an original diſeaſe, but a ſymptom only of many, in the cure regard muſt be had to the firſt cauſe: thus, as it is an attendant on ſurfeits, fevers, worms, &c. the removal of this complaint muſt be variouſly effected.

SECT. IX. *Mange.*

In a mangy horſe the ſkin is generally tawny, thick, and full of wrinkles, eſpecially about the mane, the loins, and tail; and the little hair that remains in thoſe parts ſtands almoſt always ſtraight out or briſtly; the ears are commonly naked and without hair, the eye and eye-brows the ſame; and when it affects the limbs, it gives them the ſame aſpect: yet the ſkin is not raw, nor peels off, as in the hot inflamed ſurfeit. Where this diſtemper is caught by infection, if taken in time it is very eaſily cured: and we could recommend a ſulphur ointment as moſt effectual for that purpoſe, rubbed in every day. To purify and cleanſe the blood, give antimony and ſulphur for ſome weeks after. There are a great variety of external remedies for this purpoſe.

Take of the weak mercurial ointment half a pound; ſulphur vivum four ounces; white hellebore (in powder) and oil of tartar, each one ounce. To ſoften the ointment add a proper quantity of olive oil. But when this diſorder is contracted by low feeding, and poverty of blood, the diet muſt be mended, and the horſe, properly indulged with hay and corn. The following ointments are effectually uſed for this diſorder rubbed into the parts affected every day:

Take powdered brimſtone, train oil, and tar, of each equal quantities; to which may be added ginger, or white hellebore. Or, Take ſulphur vivum half a pound, crude ſal armoniac one ounce, hogs lard or oil, a ſufficient quantity to form into an ointment.

SECT. X. *The Farcin or Farcy.*

The farcy is properly a diſtemper of the blood veſſels, which generally follows the tract of the veins, and, when inveterate, thickens their coats and integuments, ſo that they become like ſo many chords. At firſt, one or more ſmall ſwellings, or round buds like grapes or berries, ſpring out over the veins, and are often exquiſitely painful to the touch; in the beginning they are hard, but ſoon turn into ſoft bliſters, which when broke diſcharge an oily or bloody ichor, and turn into very foul and ill-diſpoſed ulcers. In ſome horſes it appears on the head only; in ſome on the external jugular; in others on the plate-vein, and runs downwards on the inſide of the fore-arm towards the knee, and very often upwards towards the briſket: in ſome the farcy ſhews itſelf on the hind-parts, about the paſterns, and along the large veins on the inſide of the thigh, riſing upwards into the groin, and towards the ſheath; and ſometimes the farcy makes its appearance on the flanks, and ſpreads by degrees towards the lower belly, where it often becomes very troubleſome. This diſtemper, being of an inflammatory nature, and in a particular manner affecting the blood-veſſels, muſt neceſſarily require large bleeding, particularly where the horſe happens to be fat and full of blood. This always checks the beginning of a farcy, but is of ſmall ſervice afterwards; and if a horſe is low in fleſh, the loſs of too much blood ſometimes proves injurious. After bleeding, let the horſe have four ounces of cream of tartar and lenitive electuary: which may be given every other day for a week, to cool the blood and the body: and then give nitre three ounces a-day for three weeks or a month, and anoint the buds or ſwellings with the following ointment twice a-day:

Take ointment of elder four ounces, oil of turpentine two ounces, ſugar of lead half an ounce, white vitriol powder two drams; mix together in a gally-pot.

When the farcin affects the large blood veſſels, the cure is more difficult; but let it always be attempted early: therefore, on the plate, thigh, or neck veins appearing chorded, bleed immediately on the oppoſite ſide, and apply the following to the corded vein:

Take oil of turpentine in a pint bottle ſix ounces, oil of vitriol three ounces; drop the oil of vitriol into the oil of turpentine by little at a time, otherwiſe the bottle will burſt; when it has done ſmoaking, drop in more oil of vitriol, and ſo on till all is mixed.

This mixture is one of the beſt univerſals in the beginning of a farcy; but where it is ſeated in looſe fleſhy parts, as flanks or belly, equal parts of the oil of vitriol and turpentine are neceſſary. Rub the parts firſt with a woollen cloth, and then apply ſome of the mixture over the buds, and wherever there is any ſwelling, twice a day. Give the cooling phyſic every other day, and then apply ſome of the mixture over the buds, and wherever there is any ſwelling, twice a day. Give the cooling phyſic every other day, and then three ounces of nitre every day for ſome time. The following balls are proper in every ſtate of the farcy; and when the diſtemper has been in its infancy, before the ſkin was much defaced, has often cured it in a week or two, by giving them only once or twice a day: but in an old farcy they ſhould be given for two or three months together.

Take of native cinnabar, or cinnabar of antimony, eight ounces; long bithwort and gum guiacum powdered, of each four ounces: make into a paſte with honey, and form into balls of the ſize of a large walnut, and roll them into liquorice powder.

Before we cloſe this ſection, it is proper to lay down the ſymptoms of an incurable farcy, that the owners of ſuch horſes may ſave themſelves unneceſſary expence and trouble in their endeavours to obtain a cure. When a farcy, by improper applications, or by neglect, has ſpread and increaſed, or after long continuance reſiſted the medicines above recommended; if freſh buds are continually ſpouting forth, while the old ones remain foul and ill-conditioned; if they riſe on the ſpines of the back and loins; if the horſe grows hide-bound, and runs at the noſe; if abſceſſes are formed in the fleſhy parts between the interſtices of the large muſcles; if his eyes look dead and lifeleſs; if he forſakes his food, and ſcours often, and his excrements appear thin and of a blackiſh colour; if the plate or thigh vein continues large and chorded after firing and other proper applications; theſe ſymptoms denote the diſtemper to have penetrated internally, and that it will degenerate into an incurable conſumption: it is moſt probable alſo that the whole maſs of fluids are tainted, and become irremediable by art.

CLASS IV.

SECT. XI. *Poll-Evil.*

The poll-evil is an abſceſs near the poll of a horſe, formed in the ſinuſes between the poll-bone and the uppermoſt vertebræ of the neck. If it proceeds from blows, bruiſes, or any external violence, at firſt bathe the ſwelling often with hot vinegar; and if the hair be fretted off with an ouzing through the ſkin, make uſe of two parts of vinegar, and one of ſpirit of wine; but if there be an itching, with heat and inflammation, the ſafeſt way is to bleed, and apply poultices with bread, milk, and elder flowers: this method, with the aſſiſtance of phyſic, will frequently diſperſe the ſwelling and prevent this evil. But when the tumour is critical, and has all the ſigns of matter, the beſt method then is to forward it by applying ripening poultices, till it comes to maturity, and burſts of itſelf: or if opened with a knife, great care ſhould be taken to avoid the tendinous ligament that runs along the neck under the mane; when matter is on both ſides, the opening muſt be made on each ſide, and the ligament remain undivided. If the matter flows in great quantities, reſembles melted glue, and is of an oily conſiſtence, it will require a ſecond inciſion, eſpecially if any cavities are diſcovered by the finger or probe; theſe ſhould be opened by the knife, the orifices made depending, and the wound dreſſed with the common digeſtive of turpentine, honey, and tincture of myrrh, and, after digeſtion, with the precipitate ointment; or waſh with the following made hot, and fill up the cavity with tow ſoaked in it:

Take vinegar or ſpirit of wine half a pint, white vitriol diſſolved in ſpring-water half an ounce, tincture of myrrh four ounces.

This may be made ſharper by adding more vitriol; but if the fleſh is very luxuriant, it ſhould firſt be pared down with a knife before the application. Taplin reprobates the practice of ſcalding in this diſeaſe, as the farriers term it, with as much ſeverity as he does that of firing in other caſes; and recommends in the firſt ſtage of it, fomentation with warm vinegar, rubbing upon the part affected immediately after about an ounce of camphorated ſpirits of wine, and then bandaging over it, a double flannel dipped in vinegar, warm as bfeore. Should the diſeaſe reſiſt this mode of treatment, he diſſuades from farther attempts by repellents to oppoſe the progreſs of nature; and recommends every means to promote ſuppuration.

SECT. XII. *Fiſtula.*

Bruiſes on the withers frequently impoſthumate, and for want of care turn fiſtulous. They ariſe often from pinches of the ſaddle, and ſhould be treated in their early ſtate with repellers; for this purpoſe bathe the tumour well with hot vinegar three or four time a-day; if that does not ſucceed, an ounce of oil of vitriol may be put to a quart of vinegar, or half an ounce of white vitriol diſſolved in a little water, and added to the ſame quantity. Theſe are generally very effectual repellers for this purpoſe in horſes, and will frequently prevent impoſthumation; when the ſwelling is attended with heat, ſmarting, and little hot watery pimples, the following mixture will then be more proper to bathe with:

Take two ounces of crude ſal ammoniac, boiled in a quart of lime-water; where that cannot be had, a handful of pearl or wood aſhes may be boiled in common water; pour off the decoction when ſettled, and mix with it half a pint of ſpirit of wine; anoint the part afterwards with linſeed oil, or elder ointment, to ſoften and ſmooth the ſkin.

But when the ſwellings are critical, the conſequence of a fever ſettled on this part, you muſt avoid the repelling method, and aſſiſt in bringing the ſwelling to matter, by means of ſuppurating poultices: experienced practitioners adviſe, never to open theſe tumours till they break of themſelves; for if they are opened before they are ripe, the whole ſore will be ſpongy, and diſcharge a bloody ichor, which ſoon degenerates into a ſordid ulcer. But take care to enlarge the openings, and pare away the lips, that your dreſſings may be applied eaſily; and avoid the ligament which runs along the neck to the withers; if a gathering forms on the oppoſite ſide, open it in the ſame manner; but take care they incline downwards, for the ſake of depending orifices, and letting the matter flow off eaſily. For the method of dreſſing, we muſt refer to the preceding Section; and if the bones ſhould be foul, they muſt be dreſſed with tincture of myrrh till they ſcale off; if the fungus is very troubleſome, and the diſcharge oily, yellow, and viſcid, pledgets, ſoaked in the following, made hot, have been found very effectual, bathing the ſwelling round with ſpirit of wine and vinegar.

Take half an ounce of blue vitriol diſſolved in a pint of water; oil of turpentine, and rectified ſpirit of wine, of each four ounces; white-wine vinegar, ſix ounces; oil of vitriol and Ægyptiacum, of each two ounces.

When the cavities are truly fiſtulous, the calloſities muſt be cut out, where it can be done, with a knife: and the remainder deſtroyed by corroſives, viz. precipitate, burnt alum, and white vitriol, as we ſhall obſerve in the following ſection.

SECT. XIII. *Ulcers.*

We ſhall not here enter into a deſcription of each particular ſpecies of ulcers, but only lay down ſome directions for their general treatment; by which means we ſhall avoid the uſual prolixity of authors on this ſubject, and yet give ſo general an idea of the nature of ulcers, as we hope will be ſufficiently inſtructive both of the application, and of the proper remedy to each. It may be neceſſary to obſerve, that we may often in vain purſue the beſt methods of cure by external applications, unleſs we have recourſe to proper internal remedies; for as all ulcers, difficult to heal, proceed from a particular indiſpoſition of the blood and juices, before the former can be brought into any order, the latter muſt be corrected by alteratives and ſweetening medicines. The firſt intention in the cure of ulcers is bringing them to digeſt, or diſcharge a thick matter; which will, in general, be effected by the green ointment, or that with precipitate; but ſhould the ſore not digeſt kindly by theſe means, but diſcharge a gleety thin matter, and look pale, you muſt then have recourſe to warmer dreſſings, ſuch as balſam, or oil of tupentine, melted down with your common digeſtive, and the ſtrong-beer poultice over them; it is proper alſo in theſe kinds of ſores, where the circulation is languid, and the natural heat abated, to warm the part, and quicken the motion of the blood, by fomenting it well at the time of dreſſing; which method will thicken the matter, and rouſe the native heat of the part, and then the former dreſſings may be re-applied. If the lips of the ulcer grow hard or callous, they muſt be pared down with a knife, and afterwards rubbed with the cauſtic. Where ſoft fungous fleſh begins to riſe, it ſhould carefully be ſuppreſſed in time, otherwiſe the cure will go on but ſlowly; if it has already ſprouted above the ſurface, pare it down with a knife, and rub the remainder with a bit of cauſtic; and to prevent its riſing again, ſprinkle the ſore with equal parts of burnt alum and red precipitate; or waſh with the ſublimate water, and dreſs with dry lint even to the ſurface, and then roll over a compreſs of linen as tight as can be borne, for a proper degree of preſſure, with mild applications, will always cauſe theſe ſpongy excreſcences to ſubſide, but without bandage the ſtrongeſt will not ſo well ſucceed. If theſe ſhould not ſucceed, the following, which is of a ſharp and cauſtic nature, is recommended on Mr. Gibſon's experience.

Take of Roman vitriol half an ounce; diſſolve in a pint of water; then decant and pour off gently into a large quart-bottle; add half a pint of camphorated ſpirit of wine, the ſame quantity of the beſt vinegar, and two ounces of Egyptiacum.

This mixture is alſo very ſucceſsfully applied to ulcerated greaſy heels, which it will both cleanſe and dry up. Theſe ſinuſes, or cavaties, frequently degenerate into fiſtulæ, that is, grow pipey, having the inſide thickened, and lined, as it were, with a horny callous ſubſtance. In order to their cure, they muſt be laid open, and the hard ſubſtance all cut away; where this is impracticable, ſcarify them well, and truſt to the precipitate medicine made ſtrong, rubbing now and then with cauſtic, butter of antimony, or equal parts of quickſilver and aquafortis. Where the cure does not properly ſucceed, mercurial phyſic ſhould be given, and repeated at proper intervals: and to correct and mend the blood and juices, the antimonial and alterative powders, with a decoction of guaiacum and lime waters, are proper for that purpoſe.

SECT. XIV. *Wounds in general.*

In all freſh wounds made by cutting inſtruments, there is nothing more required than bringing the lips of the wound into contact by future or bandage, provided the part will allow of it; for on wounds of the hips, or other prominent parts, and acroſs ſome of the large muſcles, the ſtitches are apt to burſt on the horſe's lying down and riſing up in the ſtall. In ſuch caſes, the lips ſhould not be brought cloſe together; one ſtitch is ſufficient for a wound two inches long: but in large wounds, they ſhould be at an inch or more diſtance; and if the wound is deep in the muſcles, care ſhould be taken to paſs the needles proportionably deep, otherwiſe the wound will not unite properly from the bottom. Should the wound bleed much from an artery divided, the firſt ſtep ſhould be to ſecure it, by paſſing a crooked needle underneath, and tying it up with a waxed thread; if the artery cannot be got at this way, apply a button of lint or tow to the mouth of the bleeding veſſels, dipped in a ſtrong ſolution of blue vitriol, ſtyptic water, oil of vitriol, or hot oil of turpentine, powdered vitriol, or colcothar, &c. and remember to apply it cloſe to the mouth of the bleeding veſſels, and take care that it is kept there by proper compreſs and bandage till an eſchar is formed; otherwiſe it will elude your expectations, and frequently alarm you with freſh bleedings. In a memoir preſented to the Royal Academy of Sciences by M. La Foſſe, he gives an account of the ſucceſs he had met with in ſtopping the bleedings of very conſiderable arteries in horſes, by the application of the powder of puff-balls, the arteries cicatrizing by this means only, without any ſucceeding hæmorrhage. The lycoperdon, or puff-ball, was made uſe of for this purpoſe in human ſubjects, about 170 years ago, by Felix Wurtz, a famous old ſurgeon in Germany; but he does not ſeem to have thought of truſting to it in ſuch conſiderable arteries as M. La Foſſe mentions, viz. thoſe of the leg and thigh, the bleedings from which divided veſſels he ſtopt in a few minutes by the uſe of this powder only. The agario of the oak may alſo be uſed for this purpoſe, where it can be retained by a proper bandage. Theſe applications, as indeed all ſtyptics ſeem to act by conſtringing the extremity of the veſſel, or choaking it up, till a grume of blood is formed internally, which plugs up the orifice; and has been found to adhere to it ſo as to conſtitute one body with the veſſel. We avoid ſetting down any famous receipts for freſh wounds, whether ointments, or Friar's balſams; being well aſſured, that, in a healthy ſound conſtitution, nature furniſhes the beſt balſam, and performs herſelf the cure, which is ſo often attributed to the medicine; when it is otherwiſe, and the blood is deprived of its balſamic ſtate, as will appear from the aſpect of the wound and its manner of healing, it muſt be rectified by proper internal medicines, before a good foundation for healing can be laid by any external application whatever. The lips of the wound then being brought together by the needle or bandage, it needs only to be covered with rags dipped in brandy, or a pledget of tow ſpread with the wound ointment; (ſee *Tumours*) the directions in the preceding ſections being obſerved and the wounded part kept as much as poſſible from motion. Punctured wounds from thorns, or any other accidents, ſhould be treated in the ſame manner; applying the beer or bread and milk poultice over the dreſſing, till ſome ſigns of digeſtion appear; and fomenting the part well every day. This method is alſo very ſucceſsfully uſed to thoſe ſwellings which often ariſe on the neck from bleeding; the ſores being ſprinkled with precipitate, and burnt alum powdered, to fetch out the core, or fungus, which choaks up the orifice. The uſual method is to introduce a piece of vitriol, or ſublimate, which often brings on a plentiful diſcharge, fetches out the core, and makes a cure; but it is often with the loſs of the vein, and it ſometimes leaves a large ſwelling and impoſthumation.

CLASS V.

SECT. XV. *Tumours.*

Tumours, or ſwellings, ariſe either from external injuries, or internal cauſes. Swellings cauſed by external accidents, as blows and bruiſes, ſhould at firſt be treated with reſtringents; thus, let the part be bathed frequently with hot vinegar or verjuice; and, where it will admit of bandage, let a flannel wetted with the ſame be rolled on: if by this method the ſwelling does not ſubſide, apply, eſpecially on the legs, a poultice with red wine lees, ſtrong-beer grounds, and oatmeal, or with vinegar, oil, and oatmeal: either of theſe may be continued twice a day, after bathing, till the ſwelling abates; when, in order to diſperſe it entirely, the vinegar ſhould be changed for camphorated ſpirit of wine, to four ounces of which may be added one of ſpirit of ſal armoniac; or it may be bathed with a mixture of two ounces of crude ſal armoniac boiled in a quart of chamber ley twice a-day, and rags dipped in the ſame may be rolled on. Fomentation made by boiling wormwood, bay leaves and roſemary, and adding a proper quantity of ſpirits, are often of great ſervice to thin the juices, and fit them for tranſpiration; eſpecially if the injury has affected the joints. But in bruiſes, where the extravaſated blood will not by theſe means be diſperſed, the ſhorteſt way is to open the ſkin, and let out the grumes. Critical tumours, or ſwellings, which terminate fevers, ſhould by no means be diſperſed; except when they fall on the paſtern or coffin joint, ſo as to endanger them: in this caſe the diſcutient fomentation, under the Article *Strain*, ſhould be applied three or four times a-day, and a cloth or flannel frequently wrung out of the ſame ſhould be bound on, in order to keep the joint continually breathing. But if the ſwelling fixes under the jaws, behind the ears, on the poll, withers, or in the groins and ſheath, &c. it ſhould be encouraged and forwarded by ripening poultices wherever they can be applied; oatmeal boiled ſoft in milk, to which a proper quantity of oil and lard is added, may anſwer this purpoſe; or the poultice recommended in the Section of *Strangles*; theſe muſt be applied twice a-day, till the matter is perceived to fluctuate under the fingers, when it ought to be let out; for which purpoſe, let the tumour be opened with a knife or ſtrong lancet, the whole length of the ſwelling, if it can be done ſafely; for nothing contributes ſo much to a kind healing, as the matter's having a free diſcharge, and the opening's being big enough to dreſs to the bottom. Pledgets of tow, ſpread with black or yellow baſilicon, or the wound ointment, and dipped in the ſame, melted down with a fifth part of oil of turpentine,

pentine, ſhould be applied to the bottom of the ſore, and filled up lightly with the ſame, without cramming: it may be thus dreſſed once or twice a-day, if the diſcharge is great, till a proper digeſtion is procured; when it ſhould be changed for pledgets ſpread with the red precipitate ointment, applied in the ſame manner. Should the ſore not digeſt kindly, but run a thin water and look pale, foment, as often as you dreſs, with the above fomentation; and apply over your dreſſing the ſtrong-beer poultice, and continue this method till the matter grows thick, and the ſore florid. The following ointments will generally anſwer your expectations in all common caſes; and may be prepared without, as well as with, the verdigreaſe.

Take Venice turpentine and bees-wax of each a pound, oil of olives one pound and a half, yellow roſin 12 ounces; when melted together, two or three ounces of verdigreaſe, finely powdered, may be ſtirred in, and kept ſo till cold, to prevent its ſubſiding.

Take of yellow baſilicon or the above ointment, without verdigreaſe, four ounces; red precipitate, finely powdered, half an ounce: mix them together cold with a knife or ſpatula.

It may be neceſſary to obſerve here, that the cures of moſt ſores are effected by the ſimpleſt methods; and that it is often of much more conſequence to know how to dreſs a ſore, than what to dreſs it with. And in this conſiſts indeed the chief art of this branch of ſurgery: for the moſt eminent in that profeſſion have long ſince diſcovered, that variety of ointments and ſalves are unneceſſary in the cure of moſt wounds and ſores; and they have accordingly diſcarded the greateſt part formerly in repute for that purpoſe; repeated obſervations having taught them, that, after the digeſtion, nature is generally diſpoſed to heal up the wound faſt enough herſelf; and that the ſurgeon's chief care is to prevent a luxuriancy, commonly called proud fleſh; which all ointments, wherein lard or oil enters, are but too prone to encourage, as they keep the fibres too lax and ſupple; and which dry lint alone, early applied, as eaſily prevents, by its abſorbing quality, and light compreſſion on the ſprouting fibres. As ſoon then as a good digeſtion is procured (which is known by the thickneſs and whiteneſs of the matter diſcharged, and the florid red colour at the bottom of the ſore) let the dreſſings be changed for the precipitate medicine; or the ſore may be filled up with dry lint, alone, or dipped in lime water with a little honey and tincture of myrrh, or brandy, about a fifth part of the latter to one of the former: a pledget of lint, dipped in this mixture, ſhould alſo be applied to the bottom of the ſore, which ſhould be filled up with others to the ſurface or edges, but not crammed in too hard, as before obſerved, nor yet applied too looſely. By this method, the ſore would incarn, or heal up properly, and ſoft ſpongy fleſh would be prevented or ſuppreſſed in time; whereas when ointments or ſalves are too long continued, a fungus, or proud fleſh, is thereby ſo encouraged in its growth, that it requires ſome time to deſtroy and eat it down again: a proper compreſs of cloth, and a linen roller, is abſolutely neceſſary, both for this purpoſe, and to ſecure on the dreſſings, wherever they can conveniently be applied.

SECT. XVI. *Warbles. Sitfaſt.*

Warbles are ſmall hard tumours under the ſaddle-part of the horſe's back, occaſioned by the heat of the ſaddle in travelling, or its uneaſy ſituation. A hot greaſy diſh-clout, at firſt frequently applied, will ſometimes remove them. Camphorated ſpirits of wine are alſo very effectual for this purpoſe to diſperſe them, to which a little ſpirit of ſal armoniac may be added. The repellers above-mentioned are ſucceſsfully applied in theſe caſes; and if you are obliged to work the horſe, take care your ſaddle is nicely chambered. Mr. Taplin relinquiſhes the idea of applying the hot greaſy diſh-clout, recommended by Bracken, from the difficulty and inconvenience of procuring a piece of fat beef, or gammon of bacon, in ſome countries, and to ſome pockets, and recommends the following ſubſtitute as more eaſily obtained.

Take extract of ſaturn half an ounce; camphorated ſpirits of wine, two ounces; ſoft water, quarter of a pint. Mix the extract with the ſpirits, by ſhaking them well together, and then add the water. Uſe this till the tumour is diſpelled.

A ſit-faſt proceeds generally from a warble, and is the horſe's hide turned horny; which, if it cannot be diſſolved and ſoftened by rubbing with the mercurial ointment, muſt be cut out, and treated then as a freſh wound.

CLASS VI.

SECT. XVII. *Colds.*

By taking cold, we mean that the pores and outlets of the ſkin (which in a natural healthy ſtate of body are continually breathing out a fine fluid, like the ſteam ariſing from hot water, or ſmoke from fire) are ſo far ſhut up, that theſe ſteams, or perſpirable matter, not having a free paſſage through them, are hindered from going off in the uſual manner; the conſequence of which is, their recoiling on the blood, vitiating its quality, overfilling the veſſels, and affecting the head, glands, or kernels of the neck and throat, the lungs, and other principal parts. To enumerate the various cauſes of colds would be endleſs; the moſt uſual are, riding horſes till they are hot, and ſuffering them to ſtand in that condition where the air is cold and piercing; removing a horſe from a hot ſtable to a cold one, and too ſuddenly changing his cloathing, whence it is that horſes often catch ſuch ſevere colds after they come out of dealers hands; and by not being carefully rubbed down when they come in hot off journeys. The ſigns of a horſe's catching cold, are a cough, heavineſs and dullneſs, which affect him more or leſs in proportion to the ſeverity of it; the eyes are ſometimes moiſt and watery, the kernels about the ears and under the jaws ſwell, the noſe gleets, and he rattles in his breathing; and when the cold is violent, the horſe will be feveriſh, his flanks work, and he will both loath his hot meat and refuſe his water. When theſe laſt ſymptoms are attended with a ſlimy mouth, ears, and feet cold, and a great inward ſoreneſs, there is danger of a bad fever. But when the horſe coughs ſtrong, ſnorts after it, is but little off his ſtomach, pricks up his ears, and moves briſkly in his ſtall, dungs and ſtales freely, his ſkin feels kindly, and his coat does not ſtare, he is in no danger, and there will be no occaſion for medicines of any kind; but you ſhould bleed him about two quarts, keep him warm, and give him feeds of ſcalded bran, with as much warm water as he will drink, in order to dilute his blood. If the diſorder ſhould increaſe, the horſe feel hot, and refuſe his meat, bleed him, if ſtrong, two quarts more; and if you are not ſatisfied without giving medicines, avoid, as you would poiſon, a farrier's drench; (which is generally compoſed of ſome hot, nauſeous powders, given in a quantity of ale; which too often increaſes the fever by overheating the blood, and palls the horſe's ſtomach by its loathſomneſs:) and inſtead of it, infuſe two ounces of anniſeed, with a dram of ſaffron, in a pint and a half of boiling water; pour off the clear liquor, and diſſolve in it four ounces of honey, to which may be added four ſpoonfuls of ſallad-oil; this drink may be given every night; or one of the following balls, provided there is no fever, in which caſe it always will be more eligible to give two or three ounces of nitre or ſalt prunella every day in his feeds or water till it is removed; but ſhould the horſe be inclined to coſtiveneſs, remember that his body ſhould be kept open by emollient glyſters, or cream of tartar diſſolved in his water, to the quantity of three or four ounces a-day.

Pectoral Horſe-ball. Take of the freſh powders of anniſeed, elicampane, carraway, liquorice, turmerick, and flour of brimſtone, each three ounces; juice of liquorice four ounces, diſſolved in a ſufficient quantity of mountain; ſaffron powdered half an ounce, ſallad-oil and honey half a pound, oil of anniſeed one ounce; mix together with wheat-flour enough to make them into paſte.

Theſe balls conſiſt of warm opening ingredients; and, given in ſmall quantities, about the ſize of a pullet's egg, will encourage a free perſpiration; but, in caſe of a fever, ſhould be cautiouſly continued. They are much more efficacious, and in all caſes ſuperior to the farriers drenches, if diſſolved in a pint of warm ale. This ſimple method, with good nurſing and hot maſhes, warm water and cloathing, eſpecially about the head and throat, which promotes the running at the noſtrils, will anſwer the moſt ſudden colds; and when the horſe feeds heartily, and ſnorts after coughing, moderate exerciſe every day will haſten his recovery. To a horſe loaded with fleſh, a rowel may ſometimes be neceſſary, as may alſo a gentle purge or two to ſome, when the diſtemper is gone off.

SECT. XVIII. *Cough, and Aſthma.*

The conſequence often of the preceding diſorders injudiciouſly treated, are ſettled habitual coughs; which frequently degenerate into aſthmas and broken wind. Nothing has more perplexed practitioners than the cure of ſettled coughs; the cauſe of which, perhaps, has been their want of attention to the different ſymptoms which diſtinguiſh one cough from another; for without ſtrict obſervance thereof, it is impoſſible to find out the true method of cure. Thus, if a horſe's cough is of long ſtanding, attended with loſs of appetite, waſting of fleſh, and weakneſs, it denotes a conſumption; and that the lungs are full of knotty, hard ſubſtances, called tubercles, which have often been diſcovered on diſſection. If the horſe is full of fleſh, bleed him plentifully; if low in fleſh, more ſparingly; which may occaſionally be repeated, on very great oppreſſions and difficulty of breathing, in proportionate quantities. As mercurial medicines are found remarkably uſeful in theſe caſes, give a mercurial ball, with two drams of calomel, over night, and a common purge next morning: or the following, which his recommended by Mr. Gibſon.

Take gum-galbanum, ammoniacum, and aſafœtida, of each two drams, fine aloes one ounce, ſaffron one dram, oil of anniſeed two drams, oil of amber one dram; with honey enough to form into a ball.

They may be repeated at proper intervals, with the uſual cautions. In the intermediate days, and for ſome time after, the following ball may be given every morning.

Take of the pectoral or cordial ball one pound, balſam of Peru half an ounce, balſam of ſulphur anniſated one ounce, flowers of benjamin half an ounce, honey as much as is ſufficient to form them into a paſte; give the ſize of a pigeon's egg every morning. Exerciſe in a free open air is very ſerviceable, and the diet ſhould be moderate.

The following alſo will be found a uſeful remedy in obſtinate dry coughs.

Take gum ammoniacum, ſquills, and Venice ſoap, of each four ounces ; balſam of ſulphur with anniſeeds one ounce ; beat up into a maſs, and give as the former.

Before we cloſe this ſection, it may be neceſſary to obſerve here, that ſome young horſes are ſubject to coughs on cutting their teeth ; their eyes alſo are affected from the ſame cauſe. In theſe caſes always bleed ; and if the cough is obſtinate, repeat it, and give warm maſhes ; which, in general, are alone ſufficient to remove this complaint.

SECT. XIX. *Broken Wind.*

Thoſe who are acquainted with this diſeaſe muſt own that it may be reckoned among the incurable diſtempers of horſes ; and that all the boaſted pretenſions to cure are vain and frivolous, ſince the utmoſt ſkill can amount to no more than now and then palliating the ſymptoms and mitigating their violence. We ſhall therefore lay down ſuch methods as may probably prevent this diſorder, when purſued in time. But if they ſhould not ſucceed, we ſhall offer ſome remedies and rules to mitigate its force, and make a horſe as uſeful as poſſible under this malady. It is uſual, before a broken wind appears, for a horſe to have a dry obſtinate cough, without any viſible ſickneſs or loſs of appetite ; but, on the contrary, a diſpoſition to foul feeding, eating the litter, and drinking much water. The following balls are to be taken for ſome time, which have been found extremely efficacious in removing obſtinate coughs.

TAKE aurum moſaicum, finely powdered, eight ounces ; myrrh and elicampane, powdered, each four ounces ; anniſeeds and bay berries, each an ounce ; ſaffron, half an ounce ; make into balls with oxymel ſquils.

The aurum moſaicum is made of equal parts of quickſilver, tin, ſal armoniac, and ſulphur. We give this medicine as ſtrongly recommended by Mr. Gibſon ; but how far the aurum moſaicum may contribute to its efficacy, may perhaps be juſtly diſputed : as a ſubſtitute in its room, therefore, for this purpoſe, we recommend the ſame quantity of powdered ſquils, or gum ammoniadum, or equal parts of each. Broken winded horſes ſhould eat ſparingly of hay, which as well as their corn may be wetted ; as this will make them leſs craving after water. The following alterative ball may be given once a-fortnight or three weeks : and as it operates very gently, and requires no confinement but on thoſe days it is given (when warm meat and water are neceſſary), it may be continued for two or three months.

TAKE ſocotorine aloes ſix drams ; myrrh, galbanum, and ammoniacum, of each two drams ; bay-berries half an ounce : make into a ball with a ſpoonful of oil of amber, and a ſufficient quantity of ſyrup of buckthorn.

SECT. XX. *Conſumption.*

When a conſumption proceeds from a defect in a horſe's lungs or any principal bowel, the eyes look dull ; the ears and feet are moſtly hot ; he coughs ſharply by fits ; ſneezes much, and frequently groans with it ; his flanks have a quick motion ; he gleets often at the noſe, and ſometimes throws out a yellowiſh curdled matter, and he has little appetite to hay, but will eat corn, after which he generally grows hot. As to the cure, one of the principal things is bleeding in ſmall quantities (a pint, or pint and half, from ſome horſes is ſufficient), which ſhould be repeated as often as the breath is more than ordinarily oppreſſed. Pectorals may be given to palliate preſent ſymptoms ; but as diſſections have diſcovered both the glands of the lungs and meſentery to be ſwelled, and often indurated, the whole ſtreſs lies on mercurial purges, and the following ponderous alteratives, given intermediately.

TAKE native cinnabar, or cinnabar of antimony, one pound, powdered very fine, and add the ſame quantity of gum guaiacum and nitre ; give the horſe an ounce of this powder twice a day, wetting his feeds.

The ſpring graſs is often extremely ſerviceable ; but the ſalt marſhes are to be preferred, and to be more depended on than medicines ; for great alterations are thereby made in the blood and juices, and no ſmall benefit ariſes from open air and proper exerciſe.

CLASS VII.

SECT. XXI. *Fevers.*

The ſymptoms of a fever are, great reſtleſſneſs ; the horſe ranging from one end of his rack to the other ; his flanks beat ; his eyes are red and inflamed ; his tongue parched and dry ; his breath is hot, and ſmells ſtrong ; he loſes his appetite, and nibbles his hay, but does not chew it, and is frequently ſmelling to the ground ; the whole body is hotter than ordinary, (though not parched, as in ſome inflammatory diſorders ;) he dungs often, little at a time, uſually hard, and in ſmall bits ; he ſometimes ſtales with difficulty, and his urine is high coloured ; and he ſeems to thirſt, but drinks little at a time, and often ; his pulſe beats full and hard, to fifty ſtrokes and upwards in a minute. The firſt intention of cure is bleeding, to the quantity of two quarts, if the horſe is ſtrong and in good condition ; then give him a pint of the following drink, four times a day ; or an ounce of nitre, mixed up into a ball with honey, may be given thrice a day, inſtead of the drink, and waſhed down with three or four horns of any ſmall liquor.

TAKE of baum, ſage, and commomile flowers, each a handful, liquorice-root ſliced half an ounce, ſalt prunel or nitre three ounces ; ſalt of worm-wood half an ounce ; infuſe in two quarts of boiling water ; when cold, ſtrain off, and ſqueeze into it the juice of two or three lemons, and ſweeten with honey.

His diet ſhould be ſcalded bran, given in ſmall quantities ; which if he refuſes, let him have dry bran ſprinkled with water : put a handful of picked hay into the rack, which a horſe will often eat when he will touch nothing elſe ; his water need not be much warmed, but ſhould be given often and in ſmall quantities : his cloathing ſhould be moderate ; too much heat and weight on a horſe being improper in a fever, which ſcarce ever goes off in critical ſweats (as thoſe in the human body terminate), but by ſtrong perſpiration. The various and irregular ſymptoms that attend this ſlow fever, require great ſkill to direct the cure, and more knowledge of the ſymptoms of horſes diſeaſes than the generality of gentlemen are acquainted with. The experienced farrier ſhould therefore be conſulted and attended to, in regard to the ſymptoms ; but very ſeldom as to the application of the remedy, which is generally above their comprehenſion ; though it may be readily ſelected, by duly attending to the above obſervations. The true reaſons, perhaps, why ſo many horſes miſcarry in fevers, are, that their maſters, or doctors, will not wait with patience, and let nature have fair play ; that they generally neglect bleeding ſufficiently at firſt ; and are conſtantly forcing down ſugar ſops, or other food, in a horn, as if a horſe muſt be ſtarved in a few days if he did not eat : then they ply him twice or thrice a day with hot medicines and ſpirituous drinks, which (excepting in a very few caſes) muſt be extremely pernicious to a horſe, whoſe diet is naturally ſimple, and whoſe ſtomach and blood, unaccuſtomed to ſuch heating medicines, muſt be greatly injured, and without doubt are often inflamed by ſuch treatment. Before we cloſe this ſection on fevers, it may be no improper hint to the curious to take notice, that a horſe's pulſe ſhould more particularly be attended to than is cuſtomary, as a proper eſtimate may thereby be made both of the degree and violence of the fever preſent, by obſerving the rapidity of the blood's motion, and the force that the heart and arteries labour with to propel it round. The higheſt calculation that has been made of the quickneſs of the pulſe in a healthy horſe, is, that it beats about forty ſtrokes in a minute ; ſo that in proportion to the increaſe above this number, the fever is riſing, and if farther increaſed to above fifty the fever is very high.

SECT. XXII. *Worms.*

Authors have deſcribed three different ſorts of worms that affect horſes, viz. Botts, which young horſes are often troubled with in the ſpring ; the Rotundi, or thoſe reſembling earth-worms ; and the Aſcarides, or thoſe about the ſize of the largeſt ſewing needle, with flat heads. The ſymptoms of worms are various. The botts that many horſes are troubled with in the beginning of the ſummer, are always ſeen ſticking on the ſtrait gut, and are often thurſt out with the dung ; with a yellowiſh coloured matter, like melted ſulphur ; they are no ways dangerous there ; but are apt to make a horſe reſtleſs and uneaſy, and rub his breech againſt the poſts. For the cure of botts in the ſtomach, calomel ſhould firſt be given in large quantities, and repeated at proper intervals ; Æthiops mineral, or ſome of the under-mentioned forms, may be given afterwards. But botts in the ſtrait gut may be cured by giving the horſe a ſpoonful of ſavin, cut very ſmall, once or twice a-day in his oats or bran, moiſtened ; and three or four cloves of garlick may be added to advantage. Give alſo an aloetic purge between whiles ; the following ſtands recommended.

TAKE fine ſocotorine aloes, ten drams ; freſh jalap, one dram ; ariſtolochia, or birthwort, and myrrh powdered, of each two drams ; oil of ſavin and amber, of each one dram ; ſyrup of buckthorn enough to form into a ball.

As the ſource of worms in general proceeds from a vitiated appetite and a weak digeſtion, recourſe muſt firſt be had to mercurials, and afterwards to ſuch things as are proper to ſtrengthen the ſtomach, promote digeſtion, and, by deſtroying the ſuppoſed ova, prevent the regeneration of theſe animals. Thus, two drams of calomel may be given with half an ounce of diapente, and mixed up with conſerve of wormwood, over-night ; and the next morning the above purge ; theſe may be repeated ſix or eight days. Or the following mercurial purge may be given, which will be leſs troubleſome, and no leſs efficacious.

TAKE crude quick-ſilver two drams, Venice turpentine half an ounce ; rub the quick-ſilver till no gliſtening appears : then add an ounce of aloes, a dram of grated ginger, 30 drops of oil of ſavin, and a ſufficient quantity of ſyrup of buckthorn to make a ball.

One of theſe balls may be given every ſix days, with the uſual precautions in regard to mercurial phyſic ; and the following powder intermediately.

TAKE powdered tin and Æthiops mineral of each half an ounce ; give every night in a maſh, or among his corn.

CLASS VIII.

SECT. XXIII. *Strangles.*

The ſtrangles is a diſtemper to which colts and young horſes are ſubject ; and begins with a ſwelling between the jaw-bones, which ſometimes extends to the muſcles of the tongue ; and is attended with ſo great heat, pain, and inflammation, that ſometimes, till matter is formed, the horſe ſwallows with the utmoſt difficulty.

culty. When it ariſes among the glands, and divides into ſeveral tumours, the cure is generally tedious, as it breaks in different places; and when it forms upwards on the wind-pipe and gullet, there is ſometimes danger of ſuffocation, unleſs the ſwelling ſoon breaks. But the moſt dangerous kind is, when, beſides the above ſymptoms, the horſe runs at the noſe; this is by ſome called the baſtard ſtrangles. As this diſorder ſeems to be critical, the moſt approved method is to aſſiſt nature in bringing the ſwellings to maturity, by keeping them conſtantly moiſt with ointment of marſhmallows, and covering the head and neck with a warm hood. But as all ſwellings in glandular parts ſuppurate ſlowly, the following poultice may be applied hot twice a-day.

> TAKE leaves of marſhmallows ten handfuls, white-lily root half a pound, linſeed and fenugreek-ſeed bruiſed of each four ounces: boil them in two quarts of water till the whole is pulpy; and add four ounces of ointment of marſhmallows, and a ſufficient quantity of hogs-lard, to prevent its growing ſtiff and dry.

In five or ſix days, by theſe means, the matter is generally formed, and makes its way through the ſkin; and if the diſcharge is made freely and with eaſe, the opening need not be enlarged; but ſhould be dreſſed with the following oitment ſpread on tow, ſtill continuing the poultice over it to promote the digeſtion, and prevent any remaining hardneſs.

> TAKE roſin and burgundy pitch of each a pound and a half, honey and common turpentine each eight ounces, yellow wax four ounces, hogs lard one pound, verdigreaſe finely powdered one ounce; melt the ingredients together, but do not put in the verdigreaſe till removed from the fire; and it ſhould be ſtirred in by degrees, till the whole is grown ſtiff and cool.

If the fever and inflammation run high, and the ſwelling be ſo ſituated as to endanger ſuffocation, a moderate quantity of blood muſt be taken away, and the remainder diluted with plenty of water gruel, or warm water, maſhes, &c. The running at the noſe which often attends the ſtrangles is dangerous, eſpecially if it continues after they have ripened and broke, as the horſe will be greatly weakened thereby. To prevent this waſte and decay, give him every day for ſome time an ounce of Jeſuit's bark; or a ſtrong decoction of guaiacum ſhavings, which hath been found extremely beneficial in reſtraining theſe glandular diſcharges when too liberal, and in drying up ulcers of all kinds in horſes. If a hardneſs remains after the ſores are healed up, they may be anointed with the mercurial ointment; and when the horſe has recovered his ſtrength, purging will be neceſſary. The vives or ives differ from the ſtrangles only in this; that the ſwellings of the kernels under the ears of the horſe, (which are the parts at firſt chiefly affected), ſeldom gather, or come to matter, but by degrees perſpire off and diſperſe by warm cloathing, anointing with the marſhmallow ointment, and a moderate bleeding or two. But ſhould the inflammation continue notwithſtanding thoſe means, a ſuppuration muſt be promoted by the methods before recommended in the ſtrangles. When theſe ſwellings appear in an old or full-aged horſe, they are ſigns of great malignity, and often of an inward decay as well as forerunners of the glanders. The mercurial ointment above-mentioned, may be prepared thus:

> TAKE of crude mercury or quickſilver one ounce, Venice turpentine half an ounce; rub together in a mortar till the globules of the quickſilver are no longer viſible; then add two ounces of hogs-lard.

SECT. XXIV. *Glanders.*

The matter, diſcharged from the noſtrils of a glandered horſe, is either white, yellow, or greeniſh, ſometimes ſtreaked or tinged with blood; when the diſeaſe is of long ſtanding, and the bones are fouled, the matter turns blackiſh, and becomes very fetid; and is always attended with a ſwelling of the kernels or glands under the jaws; in every other reſpect the horſe is generally healthy and ſound, till the diſtemper has been of ſome continuance. It is always a bad ſign when the matter ſticks to the inſide of the noſtrils like glue or ſtiff paſte; when the inſide of the noſe is raw, and looks of a livid or lead colour; when the matter becomes bloody, and ſtinks, and when it looks of an aſh-colour. But when only a limpid fluid is firſt diſcharged, and afterwards a whitiſh matter, the gland under the jaw not increaſing, and the diſorder of no long continuance, we may expect a ſpeedy cure; for in this caſe, which ariſes from taking cold after a horſe has been overheated, the pituitary membrane is but ſlightly inflamed, the lymph in the ſmall veſſels condenſed, and the glands overloaded, but not yet ulcerated. But Mr. De la Foſſe, the king of France's Farrier, after examining by diſſection the carcaſes of glandered horſes, and making a ſtrict ſcrutiny into the ſtate of the viſcera, aſſiſted for that purpoſe by ingenious and expert anatomiſts, for ten years together, affirms this diſeaſe to be altogether local; and that the true ſeat of it is in the pituitary membrane which lines the partition along the inſide of the noſe, the maxillary ſinuſes or cavities of the cheek bones on each ſide the noſe, and the frontal ſinuſes or cavities above the orbits of the eyes. But on nicely examining the heads of ſuch horſes, he found the cavities above mentioned more or leſs filled with a viſcous ſlimy matter, and the membrane which lines both them and the noſtrils inflamed, thickened, and corroded with ſordid ulcers, which in ſome caſes had eat into the bones. He obſerves, that when glandered horſes diſcharged matter from both noſtrils, both ſides of the membrane and cavities were affected; but when they ran at one noſtril only, that ſide only was found diſtempered. It is remarked by La Foſſe, that the ſublingual glands, or the kernels ſituated under the jaw-bone, which are always ſwelled in this diſtemper, do not diſcharge their lymph into the mouth, as in man, but into the noſtrils; and that he conſtantly found their obſtruction agreed with the diſcharge: if one gland only was affected, then the horſe diſcharged from one noſtril only; but if both were, then the diſcharge was from both. He alſo adopts the plan of trepanning theſe cavities, and taking out a piece of bone, by which means the parts affected may be waſhed with a proper injection, and in fine the ulcers deterged, healed, and dried up. There are different ſpecies of the glanders, ſo the cure of the middle kinds may firſt be attempted by injections and fumigations: thus, after taking cold, ſhould a horſe for 15 or 20 days diſcharge a limpid fluid or whitiſh matter from one or both noſtrils, the glands under the jaw rather growing harder than diminiſhing, we may expect it will degenerate into a true glanders. To prevent which, after firſt bleeding, and treating him as we have directed for a cold, let an emollient injection, prepared with a decoction of linſeed, marſhmallows, elder, camomile flowers, and honey of roſes, or ſuch like, be thrown up as faſt as poſſible with a ſtrong ſyringe, and repeated three times a day; ſhould the running not leſſen or be removed in a fortnight by the uſe of this injection, a reſtringent one may now be prepared with tincture of roſes, lime water, &c. and the noſtrils fumigated with the powders of frankincenſe, maſtich, amber, and cinnabar, burnt on an iron heated for that purpoſe; the fume of which may eaſily be conveyed through a tube into the noſtrils.

M. de la Foſſe, to whoſe opinion much deference has been paid by ſucceeding writers, diſtinguiſhes ſeven different kinds of glanders; and in order to ſupport this doctrine, cites a variety of ſymptoms, though the diſeaſe ariſes from one general cauſe, which is purulent corroſive matter diſcharged from the noſtrils, which, by being ſuffered to continue for a conſiderable time, brings ulceration on the parts where it is lodged. So that we cannot acquieſce with M. de la Foſſe's opinion in this particular, any more than in that of trepanning, which is not only a moſt painful operation, but alſo attended with ſuch trouble and expence; that admitting recovery, it muſt be an extraordinary horſe to compenſate the account. And we cannot but agree with Taplin in opinion, that when the diſeaſe is arrived to ſuch a pitch, that notwithſtanding every medicinal effort, the whole carcaſe is emaciated, and the frame ſinking under univerſal depreſſion, the firſt loſs will be ultimately beſt in a reſignation of the hide to the collar-maker, and the remains to the hounds. Nor can we refrain from concurring with the very facetious remark of that author; on the cruelty of dooming three horſes to death which had been trepanned, ſyringed, and completely cured by M. La Foſſe, "in twenty-ſix days," unleſs we are to conceive the poſſibility of "putting them to death" on the twenty-ſixth day, to avoid their natural diſſolution on the twenty-ſeventh.

SECT. XXV. *Staggers, and Convulſive Diſorders.*

FARRIERS generally include all diſtempers of the head under two denominations, viz. ſtaggers and convulſions, wherein they always ſuppoſe the head primarily affected. But in treating theſe diſorders, we ſhall diſtinguiſh between thoſe that are peculiar to the head, as having their ſource originally thence; and thoſe that are only concomitants of ſome other diſeaſe. In an apoplexy a horſe drops down ſuddenly, without other ſenſe or motion than a working at his flanks. All that can be done is to empty the veſſels as ſpeedily as poſſible, by ſtriking the veins in ſeveral parts at once, bleeding to three or four quarts; and to raiſe up the horſe's head and ſhoulders, ſupporting them with plenty of ſtraw. If he ſurvives the fit, cut ſeveral rowels; give him night and morning glyſters prepared with a ſtrong decoction of ſenna and ſalt, or the purging glyſter mentioned in the directions; blow once a-day up his noſtrils a dram of powder of aſarabacca, which will promote a great diſcharge; afterwards two or three aloetic purges ſhould be given; and to ſecure him from a relapſe, by attenuating and thinning his blood, give him an ounce of equal parts of antimony and crocus metallorum for a month; or, which is preferable, the ſame quantity of cinnabar of antimony and gum guaiacum. As to the other diſorders of the head, ſuch as lethargy or ſleeping evil, epilepſy or falling-ſickneſs, vertigo, frenzy, and madneſs, convulſions, and paralytical diſorders, as they are moſt of them to be treated as the apoplexy and epilepſy, by bleeding and evacuations, with the alteratives there directed, we ſhall wave treating of them ſeparately, but mention ſome particular rules to diſtinguiſh them, according to the plan we laid down, and then offer ſome general remedies for the ſeveral purpoſes.

In an epilepſy, or falling ſickneſs, the horſe reels and ſtaggers, his eyes are fixed in his head, he has no ſenſe of what he is doing, he ſtales and dungs inſenſibly, he runs round and falls ſuddenly; ſometimes he is immoveable, with his legs ſtretched out as if he was dead, except only a quick motion of his heart and lungs, which cauſes a violent working of his flanks; ſometimes he has involuntary motions, and ſhaking of his limbs, ſo ſtrong, that he has not only beat and ſpurned his litter, but the pavement with it; and with theſe alternate ſymptoms a horſe has continued more than three hours, and then has as ſurpriſingly recovered: at the going off of the fit, he generally foams at the mouth, the foam being white and dry, like what comes from a healthful horſe when he champs on the bit. But in all kinds of gripes, whether they proceed from diſorders in the guts, or retention of urine, a horſe is often up and down, rolls and tumbles about; and when he goes to lie down, generally makes ſeveral motions with great ſeeming carefulneſs, which ſhews he has a ſenſe of his pain; and if he lays ſtretched out for any time, it is generally but for a ſhort ſpace.

The lively deſcription of that univerſal cramp or convulſion, called by ſome the ſtag-evil, which ſeizes all the muſcles of the body at once, and locks up the jaws, ſo that it is impoſſible almoſt to force them open is thus deſcribed. When a horſe is ſeized, his head raiſed with his noſe towards the rack, his ears pricked up, and his tail cocked, looking with eagerneſs as an hungry horſe when hay is put down to him, or like a high ſpirited horſe when he is put upon his mettle; inſomuch that thoſe who are ſtrangers to ſuch things, when they ſee a horſe ſtand in this manner, will ſcarce believe any thing of conſequence ails him: but they are ſoon convinced, when they ſee other ſymptoms come on apace, and that his neck grows ſtiff, cramped, and almoſt immoveable: and if a horſe in this condition lives a few days, ſeveral knots will ariſe on the tendinous parts thereof, and all the muſcles both before and behind will be ſo much pulled and cramped, and ſo ſtretched, that he looks as if he was nailed to the pavement, with his legs ſtiff, wide, and ſtradling; his ſkin is drawn ſo tight on all parts of the body, that it is almoſt impoſſible to move it; and if trial be made to make him walk, he is ready to fall at every ſtep, unleſs he be carefully ſupported; his eyes are ſo fixed with the inaction of the muſcles, as give him a deadneſs in his looks; he ſnorts and ſneezes often, pants continually with ſhortneſs of breadth; and this ſymptom increaſes continually till he drops down dead; which generally happens in a few days, unleſs ſome ſudden and very effectual turn can be given to the diſtemper. In all theſe caſes the horſe ſhould firſt be bled plentifully, unleſs he is low in fleſh, old, or lately come off any hard continued duty; then you muſt be more ſparing of his blood: afterwards give the following ball.

Take aſa fœtida half an ounce, Ruſſia caſtor powdered two drams, valerian root powdered one ounce; make into a ball with honey and oil of amber.

This ball may be given twice a day at firſt; and then once waſhed down with a decoction of miſletoe or valerian ſweetened with liquorice or honey: an ounce of aſa fœtida may be tied up in a piece of ſtrong coarſe linen rag, and put behind his grinders to champ on. The laxative purges and emollient glyſters ſhould be given intermediately to keep the body open; but when the former balls have been taken a week or ten days, the following may be given once a day with the valerian decoction.

Take cinnabar of antimony ſix drams; aſa fœtida half an ounce, ariſtolochia, myrrh, and bay berries, of each two drams; make into a ball with treacle and oil of amber.

Repeated frictions are extremely ſerviceable in all convulſive diſorders, and often prevent their being jaw ſet; they ſhould be applied with unwearied diligence every two or three hours, where-ever any ſtiffneſs or contractions in the muſcles appear; for a horſe in this condition never lies down till they are in ſome meaſure removed. In paralytic diſorders, where the uſe of a limb or limbs is taken away, the internals above recommended ſhould be given, in order to warm, invigorate, and attenuate the blood; and the following ſtimulating embrocation ſhould be rubbed into the parts affected.

Take oil of turpentine four ounces, nerve ointment and oil of bays of each two ounces, camphor rubbed fine one ounce, rectified oil of amber three ounces, tincture of cantharides one ounce.

With this liniment the parts affected ſhould be well bathed for a conſiderable time, to make it penetrate; and when the hind parts chiefly are lame, the back and loins ſhould be well rubbed with the ſame. To the medicines above recommended, may be added ſnake root, contrayerva, muſtard feed, horſe radiſh root ſteeped in ſtrong beer, or wine where it can be afforded.

CLASS IX.

SECT. XXVI. *Colics, or Gripes.*

There ſeems to be no diſtemper ſo little underſtood by the common farriers, as the colic or gripes in horſes, one general remedy or method ſerving them in all caſes: but as this diſorder may be produced by very different cauſes, the method of cure muſt alſo vary: otherwiſe the intended remedy, injudiciouſly applied, will not only aggravate the complaint, but make it fatal. We ſhall divide this diſorder into three different ſpecies; the flatulent or windy, the bilious or inflammatory, and the dry gripes; each of which we ſhall diſtinguiſh by their different ſymptoms, and then point out the proper remedies. The flatulent or windy colic is thus known. The horſe is often lying down, and as ſuddenly riſing; when the gripes are violent, he will have convulſive twitches, his eyes are turned up and his limbs ſtretched out as if dying, his ears and feet being alternately very hot and cold; he falls into profuſe ſweats, and turns his head frequently to his flanks; falls down, rolls about and often turns on his back. This laſt ſymptom proceeds from a ſtoppage of urine that almoſt always attends this ſort of cholic, which may be increaſed by a load of dung preſſing on the neck of the bladder. Theſe are the general ſymptoms of cholic and gripes from wind, drinking cold water when hot, and when the perſpirable matter is retained, or thrown on the bowels by catching cold; in all which caſes they are violently diſtended. Cribbing horſes are more particularly ſubject to this complaint, by reaſon they are conſtantly ſucking in great quantities of air. The following ball and glyſter ſeldom fail of giving relief in theſe caſes.

Take Straſburgh or Venice turpentine, and juniper-berries pounded, of each half an ounce; ſalt-prunella or ſalt-petre, an ounce; oil of juniper, one dram; ſalt of tartar, two drams; make into a ball with any ſyrup: it may be given whole, and waſhed down with a decoction of juniper-berries, or a horn or two of ale.

If the horſe does not break wind, or ſtale plentifully, he will find no relief: therefore in an hour or two give him another ball, and add to it a dram of ſalt of amber; which may be repeated a third time, if found neceſſary. During the fit the horſe may be walked and trotted gently; but ſhould by no means be harraſſed beyond his ability, or dragged about till he is jaded. The following glyſter may be given, between the balls, or alone, and repeated occaſionally.

Take camomile flowers two handfuls; anniſe, coriander, and fennel ſeeds, of each an ounce; long pepper half an ounce; boil in three quarts of water to two; and add Daffy's elixir, or gin, half a pint; oil of amber half an ounce, and oil of camomile eight ounces.

The next ſpecies of colic we ſhall deſcribe, is the bilious or inflammatory; which beſides moſt of the preceding ſymptoms, is attended with a fever, great heat, panting, and dryneſs of the mouth; the horſe alſo generally throws out a little looſe dung, with a hot ſcalding water; which, when it appears blackiſh, or of a reddiſh colour, and fetid ſmell, denotes an approaching mortification. In this caſe the horſe ſhould immediately have an emollient glyſter, with two ounces of nitre diſſolved in it, thrown up twice a-day, to cool the inflamed bowels; plenty of gum-arabic water ſhould be taken, and a pint of the following drink given every two or three hours till ſeveral looſe ſtools are procured, and then it ſhould be given only night and morning till the diſorder is removed.

Take ſenna three ounces, ſalt of tartar half an ounce: infuſe in a quart of boiling water an hour or two; then ſtrain off, and add two ounces of lenitive electuary, and four of Glauber's ſalts.

If this diſorder is not removed by theſe means, but the inflammation and fever increaſe, attending with a diſcharge of the fleſh coloured water above deſcribed, the event will moſt probably be fatal: and the chief thing to be depended on now, muſt be a ſtrong decoction of Jeſuit's bark, given to the quantity of a pint every three hours, with a gill of red port wine. A quart of the ſame may be uſed for a glyſter, with two ounces of Venice turpentine, diſſolved with the yolks of two eggs, an ounce of diaſcordium, and a pint of red wine, and given twice a day: if the horſe recovers, give two or three mild rhubarb purges. The laſt we ſhall deſcribe is the dry gripes, or the cholic, which ariſes often from coſtiveneſs; it is diſcovered by the horſe's frequent and fruitleſs motion to dung, the blackneſs and hardneſs of the dung, the frequent and quick motion of his tail, the high colour of his urine, and his great reſtleſſneſs and uneaſineſs. An emollient glyſter ſhould be thrown up twice a day; and the above purging drink given, till the bowels are unloaded, and the ſymptoms removed. The diet for a horſe in the gripes, ſhould be ſcaled bran, warm water-gruel, or white water, made by diſſolving four ounces of gum-arabic in a quart of water, and mixing it with his other water. From this diviſion of gripes and colics, with their different treatment, it appears how abſolutely neceſſary it is they ſhould be well underſtood, in order to be managed ſkilfully; it is plain too, that violent hot medicines ſhould in every ſpecies of this diſorder be guarded againſt, and given with great caution and diſcretion, even in the firſt kind of flatulent colic, where indeed they can only be wanted; yet too often, when prepared by the farriers with oil of turpentine, geneva, pepper, brine, &c. they even increaſe that diſorder, by ſtimulating the neck of the bladder, too forcibly heating the blood, and inflaming the bowels, till a mortification is brought on them. Theſe are, in general, the conſtant appearances of horſes that die of this diſorder; whoſe bowels being examined for that purpoſe, have been found inflamed, full of red and livid ſpots, ſometimes quite black, criſped with extreme heat, and rotten.

SECT. XXVII. *Scouring and Looſeneſs.*

It is ſometimes a nice matter to form a proper judgment when to controul or encourage a looſeneſs; but theſe general rules may be a direction: if a healthy full horſe, on taking cold, or upon hard riding, overfeeding, eating unwholeſome food, or in a ſlight fever, ſhould have a moderate purging, by no means think of ſtopping it; but rather encourage it with an open diet and plenty of warm gruel; but if it continues long, with gripings, the mucus of the bowels coming away, and the horſe loſing his appetite and fleſh, it is then high time to give him proper medicines: if he voids great quantities of ſlime and greaſy matter, give him the following drench, and repeat it every other day for three times.

TAKE lenitive electuary and cream of tartar of each four ounces, yellow roſin finely powdered one ounce; and four ounces of ſweet oil: mix with a pint of water-gruel.

The following alterative ball alone has been found ſucceſsful for this purpoſe when given twice a-week, with ſcalded bran and warm gruel.

TAKE ſocotorine aloes half an ounce, diapente one ounce; make into a ball with the juice of Spaniſh liquorice diſſolved in water, and a ſpoonful of oil of amber.

To this may be added two drams of myrrh, and a dram of ſaffron, and (where it can be afforded) half an ounce of rhubarb. When the purging is attended with a fever, rhubarb ſhould firſt be given to the quantity of half an ounce, with an ounce and half of lenitive electuary; at night, after the working, give half an ounce or more of diaſcordium in a pint of red wine mulled with cinnamon; and repeat it every day, and the rhubarb-ball once in two or three. But if the diſtemper increaſes, the horſe's flanks and belly looks full and diſtended, and he appears griped and in pain; let this glyſter be given, and this quantity of diaſcordium increaſed an ounce in his night-drink.

TAKE camomile flowers one handful, red roſes half a handful, pomegranate and baulauſtines of each an ounce; boil in two quarts of water to one; ſtrain off, and diſſolve in it two or three ounces of diaſcordium, and one of mithridate; to which may be added a pint of port-wine: repeat it once a-day.

If the flux continues violent, give an ounce of rock-alum, with an ounce and a half of bole, twice a-day; or, diſſolve double this quantity with two ounces of diaſcordium, and the cordial ball, in two quarts of hartſhorn drink; to which may be added a pint of port: and give the horſe, three or four times a-day a pint of this drink. For this purpoſe alſo a ſtrong decoction of oak-bark may be given, with either of the above remedies, and to the ſame quantity; even by itſelf, it will be found on trial no inconſiderable remedy. The bloody-flux is a diſtemper horſes are not very ſubject to; however, as it ſometimes does occur, whenever blood is diſcharged, attended with gripings and great pain in the bowels, if the flux is not ſpeedily reſtrained, the horſe probably may be ſoon loſt; we recommend therefore the following glyſter and drink for that purpoſe.

TAKE oak-bark four ounces, tormentil-root two ounces, burnt hartſhorn three ounces: boil in three quarts of forge-water to two; ſtrain off, and add two ounces of diaſcordium, four ounces of ſtarch, and half a dram of opium.

SECT. XXVIII.

Diſorders of the Kidneys, Bladder, Strangury, &c.

The ſigns of the kidneys being hurt or affected are, a weakneſs of the back and loins, difficulty of ſtaling, faintneſs, loſs of appetite, and deadneſs in the eyes; the urine is thick, foul, and ſometimes bloody, eſpecially after a violent ſtrain. A horſe diſeaſed in his kidneys can ſeldom back, that is, move ſtraight backwards, without pain, which is viſible as often as he is put to the trial: the ſame thing is obſervable indeed in horſes whoſe backs have been wrung and wrenched; but with this difference, that in the latter there is ſeldom any defect or alteration in the urine, except that it is higher coloured. Bleeding is the prime remedy, and that plentifully, in order to prevent inflammation; and the more ſo, if a fever attends a difficulty in ſtaling, for then we may ſuſpect the kidneys already inflamed. A rowel in the belly has been found uſeful; and the following balls may be given twice or thrice a-day, with a pint of marſhmallow decoction, in which half an ounce of gum arabic is diſſolved, with an ounce of honey.

TAKE Locatellus-balſam one ounce, ſpermaceti ſix drams, ſal prunella half an ounce; mix into a ball with honey: if the urine is bloody, add half an ounce of Japan earth.

Should the fever continue, bleed largely, give emollient glyſters, and the cooling opening drink. If the urine paſſes with difficulty and pain, notwithſtanding theſe means, give this ball, and repeat it twice or thrice a day till the horſe ſtales freer and without pain, his urine become of a right conſiſtence, and free from any purulent ſediment.

TAKE balſam of capivi or Straſburg turpentine, and Venice ſoap, of each one ounce, nitre ſix drams, myrrh powdered two drams; make into a ball with honey, and waſh it down with the marſh-mallow decoction.

As a ſuppreſſion of urine ariſes ſometimes from an inflammation of the kidneys, ſo at others, from a paralytic diſorder, diſabling them in their office of ſeparating the urine from the blood: in this latter caſe, the bladder is uſually empty, ſo that a horſe will make no motion to ſtale; and if he continues a few days in this condition, his body will ſwell to a great degree, break out in blotches all over, and death will ſoon cloſe the ſcene. If the complaint is not removed by thoſe means, rub the horſe's reins well with two parts of oil of turpentine, and one of oil of amber; and apply a poultice of garlic, horſe radiſh, muſtard ſeed, camphor, and green ſoap, ſpread on thick cloth over them. Give the horſe alſo two drams of calomel over night, and a moderate purge the next morning. Theſe perhaps are the chief and beſt remedies that can be given in this generally fatal diſorder. When the ſtrangury in a horſe does not ariſe from wind, or dung preſſing on the neck of the bladder (as was obſerved in the ſection on Cholics), the cauſe is from inflammation, or too long a retention of the urine. Such horſes make frequent motion to ſtale, ſtand wide and ſtraddling, are full, and have their flanks diſtended. In this caſe bleed largely; give the following drink, and repeat it every two hours, for two or three times, till the horſe is relieved.

TAKE Venice turpentine, broke with the yolk of an egg, one ounce, nitre or ſal prunella ſix drams, half a pint of ſweet oil, and a pint of wine.

If this drink ſhould not have the deſired effect, the diuretic ball above mentioned may be given in the ſame manner, omitting the myrrh. Give the horſe plenty of the marſhmallow decoction: in a quart of which diſſolve an ounce of nitre and gum arabic, and two of honey. Horſes ſubject to a diabetes, or profuſe ſtaling, if old, or of a weak conſtitution, are ſeldom cured; they ſoon loſe their fleſh and appetite, grow feeble, their coat ſtaring, and they die rotten. Of a young horſe there are more hopes; but he muſt not be indulged with too much water, or moiſt food.

CLASS XI.

SECT. XXIX. *Diſeaſes of the Eyes.*

In order to make the diſorders of the eyes well underſtood, we ſhall conſider them as ariſing from different cauſes; external injuries affecting the globe of the eye; and from internal cauſes affecting the humours within the globe. We ſhall conſider alſo the eye as naturally weak from a bad conformation.

In all recent diſorders of the eye from external injuries, ſuch as blows, bites, &c. attended with a ſwelling of the lid, and a running from the eye, you muſt firſt ſponge the part often with cold ſpring-water and vinegar; and if much ſwelled, bleed immediately, and apply over it a poultice made of the pulps of roaſted or boiled apples, cleared from their ſeeds and huſks; or of conſerve of roſes and vinegar, with a little bole, and the white of an egg. When the ſwelling is abated, either of the following waſhes will complete the cure.

TAKE white vitriol half an ounce, ſugar of lead two drams; diſſolve in a pint of ſpring water; to which may occaſionally be added, when the rheum is very great, and inflammation removed, half an ounce of tutty or compound powder of ceruſs.

Let the eye and eyelid be bathed three or four times a day with a clean ſponge dipped in this waſh; or it may be applied with a feather, leaving a few drops on the eye. When the veins under the eye have been turgid, opening them with a lancet has often been found ſucceſsful. Mr. Gibſon, from his own experience, recommends the following, with which alone he has ſucceeded in many caſes.

TAKE two drams of roſe-buds, infuſe them in half a pint of boiling water: when cold, pour off the infuſion, and add to it twenty grains of ſugar of lead.

This is to be uſed as the former, but the quantity of ſugar of lead may occaſionally be increaſed. Sometimes from the violence of the inflammation, repeated blows, and external injuries, the coats of the eye ſhall loſe their tranſparency, thicken and turn white or of a dead-colour; in the latter caſe, the horſe has ſome glimmering of light; in the former, he is blind while the eye continues in this ſtate. If the horſe be fleſhy and of a groſs conſtitution, bleeding may be repeated; let his diet be ſcalded bran or barley: avoiding for ſome days oats, beans, or any thing hard to chew. A cooling opening drink, ſhould be given every other day, which will anſwer better than aloetic purges. Let it be remembered, it has long been obſerved in practice, that the eye in its firſt ſtate of inflammation is ſo very tender, that the eye-waters prepared with tutty and other powders aggravate the diſorder; conſequently, during this ſtate, the tinctures of vegetables and ſolutions of ſalts are greatly preferable. When the humours of the eye are thickened, and the diſorder is within the globe, ſharp external applications are not only uſeleſs, but extremely detrimental by the irritation they occaſion, and conſequently ſhould be avoided. In all caſes of this ſort, whether moon-eyes, which are only cataracts forming, or in confirmed ones attended with a weeping; general evacuations, with internal alteratives, can only take place.

In order to render this Syſtem as complete as poſſible, ſix plates are introduced. The firſt contains the Oſteology; the ſecond repreſents in three figures the external muſcles, with the membrana carnoſa, ligaments, &c. The four laſt contain the firſt, ſecond, third and fourth Layers of Muſcles. I have made the anatomical deſcriptions as copious as the limits of the work would admit. The methods of treatment and recipes are chiefly ſelected from the works of Bartlet, Bracken, Gibſon, La Foſſe and Taplin, which I have attentively peruſed, and in ſome inſtances altered, excepting thoſe of Taplin, which appeared to me too judicious to admit of emendation. Thoſe who wiſh to inveſtigate the ſubject ſtill further, I cannot refer to a better guide than that author.

JOHN ROBERTS,
Surgeon and Apothecary.

ACTON.

Previous to the author's commencement of this Syſtem, at his deſire I took a review of all the works upon Farriery, illuſtrated with plates and anatomical deſcriptions, but could only find thoſe of Snape and Gibſon; which were ſo indifferent, that I could not introduce them; and being unwilling that a ſubject of ſuch importance ſhould be paſſed over unnoticed, have cauſed ſix plates *to be engraved from accurate and maſterly deſigns, which I truſt will do me credit, and give ſatisfaction to my ſubſcribers.*

C. COOKE.

FARTHING, a ſmall Engliſh copper coin, amounting to one fourth of a penny. It was anciently called fourthing, as being the fourth of the integer or penny.

FASCE', in heraldry, the ſame as BARRY.

FASCETS, in glaſs making, the irons thruſt into the mouths of the bottles when made to remove into the annealing tower.

FASCIA, in architecture, a broad liſt, fillet, or band, particularly uſed in architraves and pedeſtals. See FILLET in Syſtem of *Architecture*, on the principles of the Art.

FASCIA *Lata*, in anatomy, a muſcle of the leg, called alſo muſculus membranoſus, for which ſee Syſtem of ANATOMY, Part III. Sect. XIII.

FASCIALIS, in anatomy, a muſcle of the leg, called alſo SARTORIUS; for which ſee Syſtem of ANATOMY, Part III. Sect. XIII.

FASCINATION denotes a ſort of witchcraft, ſuppoſed to operate by the influence either of the eye or the tongue.

FASCINES, in fortification, faggots, are ſmall branches of trees, or bavins, bound up in bundles, which, being mixed with earth, ſerve to fill up ditches, to ſcreen the men, make the parapets of trenches, &c. Some of them are dipped in melted pitch or tar; and, being ſet on fire, ſerve to burn the enemy's lodgments, or other works.

FASHION. The word is French, *façon*, which ſignifies *making*. Faſhion is particularly uſed among artificers, for the trouble, time, and labour, employed in a piece of work, particularly of ſilver or gold.

FAST, a ſpace of time wherein a perſon takes little or no food. For the advantages of faſting with regard to health, ſee ABSTINENCE. The Bramins never bleed their ſick, but make them faſt.

FAST, is peculiarly uſed for an abſtinence on account of religion, or a ſpace of time wherein the church prohibits the uſe of food, or at leaſt reſtrains it to certain kinds, and to certain hours. Faſting has been practiſed by moſt nations from the remoteſt antiquity. The Jews obſerved faſts from their firſt eſtabliſhment. Moſes appointed one ſolemn faſt before the feaſt of expiation; and others were inſtituted by ſeveral prophets on different occaſions. The Egyptians, Phoenicians, and Aſſyrians, neighbours to the Jews, had their faſts, as alſo the Greeks. The faſt of the Ninivites, occaſioned by the preaching of the prophet Jonas, is too well known to be inſiſted on.

Faſting muſt have been very ſacred at Rome, ſince we find it practiſed by kings and emperors. Numa Pompilius, Julius Cæſar, Auguſtus, Veſpaſian, and others, we are told, had their ſtated faſt days; and Julian the Apoſtate was ſo exact in this obſervance as even to outdo the prieſts themſelves, and the moſt rigid philoſophers. In a word, every country, nation, and religion, have had at all times their prieſts, druids, gymnoſophiſts, and philoſophers, who diſtinguiſhed themſelves by their frugality, auſterity, and abſtinence.

The Turks are ſo ſcrupulous on the point of faſting, that they will not at thoſe times ſo much as take the ſmell of any perfume by the noſe. They hold that odours themſelves break faſt. If they bathe, it is forbid to put the head under water for fear of ſwallowing any of it; and as for women, they are forbid to bathe at all on faſt-days, for a reaſon peculiar to the ſex.

Though faſting is not poſitively enjoined by Chriſt or his apoſtles, a practice prevailed among the firſt Chriſtians of joining abſtinence with their prayers, eſpecially when they were engaged in affairs of extraordinary importance. But in the moſt ancient times we find no mention of any public and ſolemn faſts, except upon the anniverſary of Chriſt's crucifixion. However, in proceſs of time, days of faſting were gradually introduced, firſt by cuſtom, and afterwards by poſitive appointment; though it is not certain what thoſe days were, nor whether they were obſerved in the firſt century.

The ancient catholics allowed of no obligatory or commanded faſts beſide that preceding Eaſter, ſince called Lent; the terms of which were to forbear eating till the evening. The other faſts obſerved were only of devotion; ſuch were the fourth and ſixth feriæ; i. e. Wedneſdays and Fridays. This Lent faſt was called ſtation. Beſides theſe, there were occaſionally faſts enjoined by the biſhops, &c. See ABSTINENCE and LENT.

FAST *Days* are thoſe appointed by public authority, to be obſerved by faſting and humiliation.

FASTI, in antiquity, the Roman calendar; wherein the ſeveral days of the years, with their feaſts, games, and other ceremonies were expreſſed. The Romans had their greater and leſſer faſti. The great faſti were called the faſti of the magiſtrates; and the leſſer, the faſti calendares.

FAT, in an animal body, a white, oily, concrete ſubſtance, collected in little membranous loculi or cells in divers parts of the body, ſerving to keep the parts warm, to ſoften and temper the acids of the aliments in the maſs of blood, and probably for the nouriſhment and reparation of the human body. See Syſtem of ANATOMY, Part I. Sect. VII.

Too much fat is uſually attended with heavineſs and drowſineſs, not only from the unwieldineſs of an overgrown body, but from the ſtuffing of the cavities and thorax alone, which ſometimes obſtructs the expanſion of the diaphragm and lungs, and produces a dyſpnoea, or an orthopnoea; and it is likewiſe probable that the abundance of fatty or oily particles returned into the blood, and implicating the more ſubtle and active parts, may hinder the neceſſary ſecretions of the brain. See CORPULENCY.

FATE, *fatum*, denotes an inevitable neceſſity depending upon a ſuperior cauſe. The word is formed *a fando*, from ſpeaking; and primarily implies the ſame with *effatum*, viz. a word or decree pronounced by God; or a fixed ſentence whereby the Deity has preſcribed the order of things, and allotted to every perſon what ſhall befall him. The Greeks called it ειμάρμενη, as it were a chain or neceſſary ſeries of things indiſſolubly linked together. It is alſo uſed to expreſs a certain unavoidable deſignation of things, by which all agents, both neceſſary and voluntary, are ſwayed and directed to their ends. The Rev. Mr. Madan introduces the following remarks on this ſubject, in the notes on his book of Hymns, page 140.

"We are glad of an opportunity to reſcue this ſignificant word out of the hands of the Infidels, who uſe it together with luck, fortune, chance, deſtiny, to promote their favourite ſcheme of excluding the particular providence of the wiſe diſpoſer of all events from the government of the affairs of men. But the word Fate (Fatum) ſignifies what is ſpoken, from the Latin word Fari to ſpeak. Fate then eminently relates to what has been ſpoken by the moſt High God: So *Minutius Felix*, that able lawyer and great ſcholar in St. Cyprian's time, ſays, *Nihil aliud eſt Fatum quam quod de unoquoque Noſtrum Deus Fatus eſt*. Fate is nothing elſe than what God hath ſpoken, concerning every one of us. Even the Heathens had this idea of it; for, ſays Statius, *Fatum eſt quod Dii Fantur*. Fate is that which the gods ſpeak."

FATHER, a term of relation denoting a perſon who hath begot a child. See PARENT and CHILD.

Natural FATHER, is he who has illegitimate children.

FATHER, in theology, is uſed in ſpeaking of the Firſt Perſon of the Trinity.

FATHER is alſo uſed in ſpeaking of ſpiritual and moral things. Thus, Abraham is called the "father of the faithful."

FATHER, in church hiſtory, is applied to ancient authors who have preſerved in their writings the traditions of the church. Thus St. Chryſoſtom, St. Baſil, &c. are called Greek fathers, and St. Auguſtine and St. Ambroſe, Latin fathers. No author who wrote later than the 12th century is dignified with the title of father.

FATHER, is alſo a title of honour given to prelates and dignitaries of the church, to the ſuperiors of convents, to congregations of eccleſiaſtics, and to perſons venerable for their age or quality. Thus we ſay, the right reverend father in God, the father-general of the Benedictines, the fathers of the council of Nice, father of his country, &c.

FATHOM, a long meaſure containing ſix feet, taken from the utmoſt extent of both arms when ſtretched into a right line. The fathom is uſed at ſea in eſtimating the length of cables and other ſhip ropes, with the depths and ſoundings of the ſea; as alſo in mines, quarries, wells, and works of fortification.

FATNESS. See CORPULENCY. It is obſerved, that for one fat perſon in France or Spain, there are an hundred in England and Holland. This is ſuppoſed to be from the uſe of new malt liquors, more than from the difference of climates or degrees of perſpiration. Indolence may cauſe fatneſs in ſome few conſtitutions: but, in general, thoſe who are diſpoſed to this habit will be fat in ſpite of every endeavour to the contrary, but that of deſtroying health.

FAUNS, FAUNI, among the ancients, were a ſpecies of demi gods inhabiting the foreſts; called alſo *Sylvans*, *Sylvani*, and little differing from the Satyrs.

FAWN, among hunters, is a buck or doe of the firſt year, or the young one of the buck's breed in its firſt year.

FEAL was anciently uſed for faithful; hence the tenants by knights ſervice uſed to ſwear to their lords to be feal and leal; that is, *faithful* and *loyal*.

FEALTY, an oath formerly taken at the admittance of every tenant, to be true to his lord, while he holds his land.

Fealty ſpecial was with us performed either by freemen or villains. By 17 Ed. II. ſtat. 2. the form of this oath is appointed, and as now obſerved it is as follows: "I A B. will be to you "my lord C. true and faithful, and bear to you fealty and faith for "the lands and tenements which I hold of you; and I will "truly do and perform the cuſtoms and ſervices that I ought to "do to you. So help me God."

FEAR, in ethics, is the apprehenſion of ſome evil likely to befal us, attended with a deſire of avoiding it. This paſſion has been found to leſſen perſpiration and urine.

FEAST, or FESTIVAL, in a religious ſenſe, is a day of feaſting and thankſgiving. Among the ancients, feaſts were inſtituted upon various accounts, but eſpecially in memory of ſome favourable interpoſition of providence. Thus, the Jews had their feaſt of paſſover, pentecoſt, and tabernacles; the Greeks their cerealia, panathenæa, &c. and the Romans their ſaturnalia, ambarvalia, &c. See PASSOVER, CEREALIA, &c.

In the ancient Chriſtian church, beſides the high feſtivals of Chriſtmas, Eaſter, Pentecoſt, Annunciation, &c. there were others inſtituted in honour of the apoſtles and martyrs: all which are retained by the church of England. See the articles CHRISTMAS, EASTER, &c. In the church of Rome, there are double, half-double, and ſimple feaſts almoſt without number. The name of double feaſts is given to ſuch whoſe ſervice is fuller and more ſolemn than the reſt, which likewiſe conſtitutes the difference between the others; the churches being embelliſhed, and the altars adorned, according to the rank which each ſaint holds in his reſpective church. All high feſtivals have an octave, conſiſting of the feaſt itſelf, and the ſeven following days. In Italy, certain feſtivals are celebrated ſolely by lovers. When a lover wants to give his miſtreſs the higheſt teſtimony of his gallantry, he immediately makes her the idol of his devotion: procuring veſpers, and even maſſes, to be ſaid to her honour. For this purpoſe he makes choice of the feſtival of ſome ſaint whoſe name ſhe bears; and though the ſaint has the ſame name, they manage matters ſo, that the devotion of the feſtival is plainly relative to the lover's miſtreſs. The four quarterly feaſts, or ſtated times, whereon rent on leaſes is uſually reſerved to be paid, are Lady-day, or the annunciation of the bleſſed virgin Mary, the 25th of March; the nativity of St. John the Baptiſt, held on the 24th of June; the feaſt of St. Michael the arch-angel, on the 29th of September; and Chriſtmas, or rather on St. Thomas the Apoſtle, on the 21ſt of December.

FEAST is alſo uſed for a banquet, or a ſumptuous meal, without any immediate view to religion. It has been often obſerved by authors, that there is no nation in the world comes near the Engliſh in the magnificence of their feaſts. Thoſe made at our coronations, inſtallments, conſecrations, &c. tranſcend the belief of all foreigners; and yet it is doubted whether thoſe now in uſe are comparable to thoſe of our forefathers. The Perſians never diſcourſe and deliberate on their moſt important affairs but in the middle of their feaſts.

FEATHER, in phyſiology, a general name for the covering of birds: it being common to all the animals of this claſs to have their whole body, or at leaſt the greateſt part of it, covered with feathers or plumage. Feathers make a conſiderable article of commerce. Thoſe from Somerſetſhire are eſteemed the beſt, and thoſe from Ireland the worſt. Eider is imported from Denmark, the ducks that ſupply it being inhabitants of Hudſon's bay, Greenland, and Norway. Our own Iſlands weſt of Scotland breed numbers of theſe birds, and might turn out a profitable branch of trade to the poor inhabitants. Hudſon's bay alſo furniſhes very fine feathers, ſuppoſed to be of the gooſe kind. The down of the ſwan is brought from Dantzic. The ſame place alſo ſends us great quantities of the feathers of the cock and hen. The London poulterers ſell a great quantity of the feathers of thoſe birds, and of ducks and turkies: thoſe of ducks being a weaker feather, are inferior to thoſe of the gooſe; and turkies feathers are the worſt of any. The beſt method of curing feathers is to lay them in a room, in an expoſure to the ſun: and when dried, to put them in bags, and beat them well with poles to get the dirt off.

Geeſe are plucked in ſome parts of Great Britain five times in the year; the firſt plucking is at Lady-day for feathers and quills; and the ſame is renewed for feathers only four times more between that and Michaelmas.

Feathers ſeem to be only productions and expanſions of the laſt extreme fibrillæ of the cutis; and hence, upon ſtripping off the cutis, the feathers are likewiſe always taken away; juſt as the leaves and fruit follow, upon peeling the bark of a tree: add, that feathers as well as hairs ariſe out of pores in the cutis: which pores are not merely apertures or foramina, but a kind of vaginulæ, wove of the fibres of the ſkin, which terminate in the oſcula or anaſtomoſes of the internal fibres of the feather.

Dr. Derham has ſeveral obſervations on the mechaniſm of the vanes or webs of the feathers as they preſent themſelves to the microſcope by which the wonderful care and accuracy of the Creator in ſo ſmall a part are excellently illuſtrated.

FEAZING, at ſea, is the ravelling out of the cable or any great rope at the ends.

FEBRIFUGE, an appellation given to ſuch medicines as mitigate or remove a fever.

FEBRUARY, in chronology, the ſecond month of the year, reckoning from January, firſt added to the calendar of Romulus by Numa Pompilius. February derives its name from *Februa*, a feaſt held by the Romans in this month, in behalf of the manes of the deceaſed: at which ceremony ſacrifices were performed, and the laſt offices were paid to the ſhades of the defunct. February, in a common year, conſiſts only of 28 days: but in the Biſſextile year, it has 29, on account of the intercalary day added that year.

FECULENT, or FÆCULENT, is applied to the blood and other humours, when they abound in fæces or dregs, or have not the proper and uſual degree of purity.

FECUNDITY, or FOECUNDITY, fertility, or that quality of a thing which denominates it fruitful. The fecundity of divers plants is very extraordinary. M. Dodart has an expreſs diſcourſe on this ſubject, in the Memoirs of the Academy of Science; wherein he ſhews, that at a moderate computation, an elm, one year with another, yields 329,000 grains or ſeeds, each of which, if properly lodged, would grow up into a tree: now an elm ordinarily lives 100 years, conſequently, in the courſe of its life it produces near 33,000,000 ſeeds, all which ariſe from one ſingle ſeed. He ſhews farther, that the ſame elm by frequently cutting off its head, &c. might be brought to produce 15,840,000,000 ſeeds, and conſequently, that there are ſo many actually contained in it.

FEE, FEUD, FEUDUM, FEODUM, or FIEF, an eſtate, land, tenement, lordſhip, or the like, held of a ſuperior lord, on condition of fealty, homage, or other acknowledgment. The term fee is properly applied to lands and tenements, which we hold in perpetual right, on condition of an acknowledgment of ſuperiority in a higher lord. See TENURE. The writers on this ſubject divide all lands and tenements wherein a man has a perpetual eſtate to him and his heirs into allodium and feudum.

Allodium is defined to be a man's own land, which he poſſeſſes merely in his own right, without acknowlegement of any ſervice or payment of any rent to another; and this is his property in the higheſt degree.

The origin of fees in England, Camden carries as far back as the time of Alexander Severus. That prince having built a wall in the North of England to prevent the incurſions of the Picts, he ſome time after began to neglect the defence thereof, and gave, as Lampridius, in Vita Alex. Severi, aſſures us, the lands conquered from the enemy to thoſe of his captains and ſoldiers, whom that author calls *limitarios duces, & milites*; i. e. captains and ſoldiers of the frontiers; but it was on this condition, that their heirs ſhould continue in the ſervice, and that the lands ſhould never deſcend to private perſons; i. e. to ſuch as did not bear arms. That prince's reaſon was, that people, who in ſerving defended their own, would ſerve with a great deal more zeal than any others. Such, according to Camden, was the riſe of fees in our nation, Britan. p. 651. However, the feudal polity originally derived from the northern nations, and gradually eſtabliſhed on the continent of Europe, was not univerſally received in England, though ſome traces of it may be diſcerned in the times of the Saxons, who were firmly ſettled in this iſland, as early as the year 600, and incorporated with the national conſtitution till the reign of William the Norman; and this was done not by the mere arbitrary will and power of the conquerory but by the univerſal conſent of the common council of the kingdom, in the ſame principle of ſelf-ſecurity which had before induced the other nations of Europe to adopt it. The æra of formally introducing the feudal tenures by law was probably the latter end of the year 1086, when the king was attended by all his nobility at Sarum, and all the principal land-holders ſubmitted their lands to the yoke of military tenure, became the king's vaſſals, and did homage and fealty to his perſon. This ingraftment of the feudal tenures and other cuſtoms of Normandy upon the ancient Saxon laws of Edward the Confeſſor produced a different political ſyſtem in this country, and changed both power and property in many reſpects; for thoſe hereditary eſtates of the Saxon nobility and gentry which were allodial, and not ſubject to any feudal ſervice, were converted into feuds, and other lands, which were of a feudal nature, and holden by military ſervice, having been granted only at will, or for a certain number of years, or at moſt for life or lives, and the grants of which were called benefices, were made hereditary fiefs. The feudal rights claimed in conſequence of this eſtabliſhment by the king over his tenants, and by them over theirs, were conſiderably mitigated by the charter of Henry II. See MAGNA *Charta*. Lord Littleton's Hiſt. of King Henry II. vol. i. p. 59. &c. vol. iii. p. 97, &c. Blackſtone's Comm. vol. ii. chap. 4.

It ſhould be obſerved, that our Engliſh lawyers do very rarely (of late years eſpecially) uſe the word fee in this its primary original ſenſe in contradiſtinction to allodium or abſolute property, but generally uſe it to expreſs the continuance or quantity of an eſtate; ſo that a fee in general ſignifies an eſtate of inheritance, being the higheſt and moſt extenſive intereſt that a man can have in a feud. Blackſtone's Comm. vol. ii. p. 106.

In the ſtat. 37 Hen. VIII. cap. 16. *fee* is alſo uſed for lands veſted in the crown; but it is from ignorance of the import of the word; for fee cannot be without fealty ſworn to a ſuperior; but the king owns fealty to no ſuperior but God alone. Fee is divided in our laws into *fee-abſolute*, called alſo *fee-ſimple*, and *fee-conditional*, alſo called *fee-tail*.

FEE *Simple*, *feudum ſimplex*, is that whereof we are ſeiſed to us and our heirs for ever. Or it denominates an abſolute inheritance, clear of any condition, limitation, or reſtriction to particular heirs, but deſcendible to the heirs general, whether male or female, lineal or collateral. It is a general rule, that the word *heirs* is neceſſary in the grant or donation, in order to make a fee or inheritance: but this rule does not extend to deviſes by will, nor to fines and recoveries conſidered as a ſpecies of conveyance, nor to creation of nobility by writ, though in creations by patent, the word *heirs* muſt be inſerted; nor to grants of lands to ſole corporations and their ſucceſſors; nor finally, to the caſe of the king, in whom a *fee-ſimple* will veſt, without the words heirs or ſucceſſors in the grant.

FEE *Tail*, *feutum taliatum*, is that whereof we are ſeiſed with limitation to us and the heirs of our body. *Fee-tail* is of two kinds, *general* and *ſpecial*. *Fee-tail general*, is where lands and tenements are given to a man and the heirs of his body begotten. So that if a man ſeiſed of ſuch land by ſuch gift may marry one or more wives, and have no iſſue by them, and at length marry another, by whom he hath iſſue, this iſſue ſhall inherit the land. *Fee tail ſpecial*, is where a man and his wife are ſeiſed of lands to them and the heirs of their two bodies; where, in caſe the wife die without iſſue, and he marry another by whom he have iſſue, this iſſue cannot inherit the land, and therefore it is called ſpecial tail. This *fee-tail ſpecial* has its origin from the ſtat. in Weſtm. 2. 13 Edw. I. cap. 1. Before that ſtatute, all land given to a man and his heirs, either general or ſpecial, was reputed in the nature of a fee; and therefore ſo firmly held to him, that, any limitation notwithſtanding, he might alienate it at pleaſure: for redreſs of which inconvenience the ſtatute provides, that if a man gives lands in fee, limiting the heirs to whom it ſhall deſcend, with a reverſion to himſelf and his heirs for default of ſuch former heirs, the form and meaning of the gift ſhall be obſerved.

Fee alſo ſignifies a reward or ordinary due given a perſon for the execution of his office, or the performance of his part in his reſpective art or ſcience. Thus, the lawyer, barriſter, and phyſician, are ſaid to have their fees; i. e. conſiderations for the pains taken with the client or patient. If a perſon refuſe to pay an officer his due fees, the court will grant an attachment againſt him, to be committed till the fees are paid: and an attorney may bring an action of the caſe for his fees againſt the client that retained him in his cauſe. Fees alſo denote ſettled perquiſites or allowances paid to public officers by perſons who have buſineſs with them.

FEELERS, antennæ, in natural hiſtory, are the horns, as they are uſually called, upon the heads of inſects. See Syſtem of Entomology. Scientific Deſcription.

FEELING, touching, one of the external ſenſes, whereby we acquire the ideas of ſolid, hard, ſoft, rough, hot, cold, wet, dry, or other tangible qualities; as alſo of diſtance, itching, pain, &c. Feeling is the groſſeſt, but at the ſame time the moſt extenſive of our ſenſes, having more objects than all the reſt taken together: and ſome even reduce all the other ſenſes to this one of feeling.

Some naturaliſts will have it in all the parts that have nervous fibres, which extends it to the ſkin, fleſh, muſcles, membranes, and parenchymas; others reſtrain it to the ſkin or cutis; it being obſerved, that only thoſe parts covered with a cutis have properly the faculty of touching, or perceiving tangible qualities. But what part of the cutis to aſſign immediately for this office is again diſputed. Some will have it the membranous parts; others the carnous; and others the medullary part, derived from the nerves. Malpighi, and after him all our lateſt and beſt authors, hold the immediate organ of the ſenſe of feeling to be the pyramidal papillæ under the ſkin.

Theſe papillæ are little, ſoft, medullary, nervous prominences, lodged every where immediately under the cuticula. They are formed of the ſubcutaneous nerves, which, for this purpoſe, firſt lay aſide their outer membrane, and are left exceedingly ſoft and ſenſible; are continually moiſtened by a thin ſubtle humor, and only covered over and defended by the cuticle or ſcarf- ſkin.

Feeling, then, is thus affected: the tip of the finger for inſtance, being applied to an object to be examined, by that intention of the mind the papillæ are emitted or elevated, and being lightly rubbed over the ſurface of the object, a motion is impreſſed on them, which being thence propagated by the nerves communicating with them to the common ſenſory, excites the perception of heat, cold, hardneſs, or the like. Hence we ſee why feeling becomes painful when the cuticle is worn off, burn, macerated, &c. and why, when the cuticle becomes thick, hard, callous, or cicatrized, &c. the ſenſe of feeling is loſt; elſe whence the numbneſs impreſſed by the torpedo? why that exquiſite painfulneſs under and at the roots of the nails? &c.

FEINT, in fencing, a falſe attack, or a ſhew of making a ſtroke or puſh in one part, with deſign to bring the enemy to guard that part, and leave ſome other part unguarded where the ſtroke is really intended. Feints are either ſingle or double, high or low, without or within, &c. in prime, in tierce, in quart, in demi, and in the whole circle; of one, two, or three meaſures. The ſimple feint is a mere motion of the wriſt, without ſtirring the foot, &c. See Treatiſe on the Art of Fencing.

FELIS, the cat, a genus of quadrupeds belonging to the order of feræ, the characters of which are theſe: the fore-teeth are equal: the molares or grinders have three points: the tongue is furniſhed with rough ſharp prickles, and pointing backwards; and the claws are ſheathed, and retractile. This genus comprehends ſeven genera, viz. The *leo*, or loin. The largeſt lions are from eight to nine feet in length, and from four to ſix feet high: thoſe of a ſmaller ſize are generally about 5½ feet long, and about 3½ high. A lion taken young, and brought up among domeſtic animals, will eaſily be accuſtomed to live and ſport with them: that he is mild and careſſing to his maſter, eſpecially when he is young, and that, if his natural ferocity ſometimes breaks out, it is rarely turned againſt thoſe who have been kind to him. But, as his paſſions are impetuous and vehement, it is not to be expected that the impreſſions of education will at all times be ſufficient to balance them; for this reaſon it is dangerous to let him ſuffer hunger long, or to vex him by ill-timed teazings; bad treatment not only irritates him, but he remembers it long, and meditates revenge. On the other hand, he is exceedingly grateful, and ſeldom forgets benefits received. He has been often obſerved to diſdain weak or inſignificant enemies, to deſpiſe their inſults, and to pardon their offenſive liberties. When led into captivity, he will diſcover ſymptoms of uneaſineſs, without anger or peeviſhneſs: on the contrary, his natural temper ſoftens, he obeys his maſter, careſſes the hand that gives him food, and ſometimes gives life to ſuch animals as are thrown to him alive for prey: by this act of generoſity he ſeems to conſider himſelf as for ever bound to protect them: he lives peaceably with them; allows them a part, and ſometimes the whole, of his food; and will rather ſubmit to the pangs of hunger, than fill his ſtomach with the fruit of his beneficence. We may likewiſe obſerve, that the lion is not a cruel animal; he kills rather from neceſſity than choice, never deſtroying more than he eats; and whenever his appetite is ſatisfied, he is mild and peaceable.

The aſpect of the lion does not detract from the noble and generous qualities of his mind. His figure is reſpectable; his looks are determined; his gate is ſtately; and his voice is tremendous. In a word, the body of the lion appears to be the beſt model of ſtrength joined to agility. The force of his muſcles is expreſſed by his prodigious leaps and bounds, often 20 feet at once; by the briſk motion of his tail, a ſingle ſweep of which is ſufficient to throw a man to the ground; by the eaſe with which he moves the ſkin of his face, and particularly of his forehead; and, laſtly, by the faculty of erecting and agitating the hair of his main when irritated.

Lions are very ardent in their amours; when the female is in ſeaſon, ſhe is often followed by eight or ten males, who roar inceſſantly, and enter into furious engagements, till one of them completely overcomes the reſt, takes peaceable poſſeſſion of the female, and carries her off to ſome ſecret receſs. The lioneſs brings forth her young in the ſpring, and produces but once every year.

All the paſſions of the lion, the ſoft paſſion of love not accepted, are exceſſive; the love of offspring is extreme: the lioneſs is naturally weaker, leſs bold, and more gentle than the lion; but ſhe becomes perfectly rapacious and terrible when ſhe has young. Then ſhe exhibits more courage than the male; ſhe regards no danger; ſhe attacks indifferently men and all other animals, kills them, and carries them to her young ones, whom ſhe thus early inſtructs to ſuck their blood and tear their fleſh. She generally brings forth in the moſt ſecret and inacceſſible places: and, when afraid of a diſcovery, ſhe endeavours to conceal the traces of her feet, by returning frequently on her ſteps, or rather by effacing them with her tail; and, when the danger is great, ſhe carries off her young, and conceals them ſomewhere elſe. But, when an actual attempt is made to deprive her of her young, ſhe becomes perfectly furious, and defends them till ſhe be torn to pieces.

The lion ſeldom goes abroad in the middle of the day; he goes in the evening and night, in queſt of prey. He is afraid of fire, and never approaches the artificial fires made by the ſhepperds for the protection of their flocks; he does not trace other animals by the ſcent, but is obliged to truſt to his eyes. Many hiſtorians have even miſrepreſented him as incapable of finding out his prey; but that he is obliged to the jackal, an animal of exquiſite ſcent, in order to provide for him, and that this animal either accompanies or goes before him for this purpoſe. The jackal is a native of Arabia, Libya, &c. and, like the lion, lives upon prey: perhaps ſometimes he follows the lion, but it is with a view to pick up what he leaves behind, not to provide for him; for, being a ſmall and feeble animal, he ought rather to fly from than to ſerve the lion.

The lion, when hungry, will attack any animal that preſents itſelf: but he is ſo very formidable, that all endeavour to avoid his rencounter; this circumſtance often obliges him to conceal himſelf, and lie in wait till ſome animal chances to paſs. He lies ſquat on his belly in a thicket; from which he ſprings with ſuch force and velocity, that he often ſeizes them at the firſt bound. He endures hunger longer than thirſt; he ſeldom paſſes water without drinking, which he does by lapping like a dog. For his ordinary ſubſiſtance, he requires about 15 pounds of raw fleſh each each day. They put a live animal above a deep pit covered with light ſubſtances, and thus decoy him into the ſnare.

The tiger is more ferocious, cruel, and ſavage than the lion. Although gorged with carnage, his thirſt for blood is not appeaſed; he ſeizes and tears in pieces a new prey with equal fury and rapacity, the very moment after devouring a former one; he lays waſte the country he inhabits; he neither dreads the aſpect nor the weapons of men; puts to death whole troops of domeſtic animals; and attacks young elephants, rhinoceros, and ſometimes even braves the lion himſelf. The tiger ſeems to have no other inſtinct but a conſtant thirſt after blood, a blind fury which knows no bounds or diſtinction, and which often ſtimulates him to devour his own young, and to tear the mother in pieces for endeavouring to defend them. He lies in wait on the banks of rivers, &c. where the heat of the climate obliges other animals to repair for drink. Here he ſeizes his prey, or rather multiplies his maſſacres; for he no ſooner kills one animal, than he flies with equal fury upon the next, with no other view but to plunge in his head into their bodies and drink their blood. However, when he kills a large animal, as a horſe or a buffalo, he ſometimes does not tear out the entrails on the ſpot; but, to prevent any interruption, he drags them off to the wood, which he performs with incredible ſwiftneſs. This is a ſufficient ſpecimen of the ſtrength of this rapacious animal.

Neither force, reſtraint, nor violence, can tame the tiger. He is equally irritated with good as with bad treatment: he tears the hand which nouriſhes him with equal fury as that which adminiſters blows: he roars and his enraged at the ſight of every living creature. Almoſt every natural hiſtorian agrees in this horrible character. The Pardus, or Panther, is about the ſize of a large dog, and has a great reſemblance to a domeſtic cat. The tongue is rough, and remarkably red; the teeth are ſtrong and ſharp; the ſkin is exceedingly beautiful, being of a yellow colour, variegated with roundiſh black ſpots, and the hair is ſhort.

The panther inhabits Africa, from Barbary to the remoteſt parts of Guinea. It has a cruel and ferocious aſpect; his motions are briſk and lively. He is not ſo perfectly ungovernable as the tiger; but, notwithſtanding all attempts to render him obedient and tractable, he may rather be ſaid to be ſubdued than tamed; for he never entirely loſes his natural ferocity. The panther, according to Buffon, is no where to be found but in Africa, and the regions of the Indies.

The onca, or once, is leſs than the panther; the tail is longer; the hair is likewiſe longer, and of a whitiſh grey colour. The once is eaſily tamed; he lies in wait for the approach of animals, and then darts upon them unawares. He leaps ſo nimbly, that he eaſily clears a ditch or a wall ſeveral feet high; beſides, he often climbs trees, waits till ſome animal paſſes, and inſtantly leaps upon them. This method of catching their prey, is practiſed by the panther and leopard, as well as by the once. The once inhabits Barbary, Perſia, Hyrcania, and China; from which laſt place the ſkins are brought into Ruſſia, and ſold for 20s. a piece.

The pardalis, or leopard, differs from the panther and the once, in the beauty of his colour, which is a lively yellow, with ſmaller ſpots than thoſe of the two latter, and diſpoſed in groups. He is larger than the once, and leſs than the panther. The leopard inhabits the Eaſt Indies; one kept ſome years ago in the Tower, ſeemed a good natured animal.

The lynx is about 2½ feet long and 15 inches high. He has a great reſemblance to the cat; but his ears are longer, and his tail is much ſhorter; his hair is ſtreaked with yellow, white, and black colours. The lynx is an inhabitant of Muſcovy, Poland, Canada, &c. His eyes are brilliant, his aſpect is ſoft, and his air is gay and ſprightly: like the cat, he covers his urine with earth; he howls ſomething like the wolf, and is heard at a conſiderable diſtance; he does not run like the dog or wolf, but walks and leaps like a cat, he purſues his prey even to the tops of the trees; neither wild cats nor ſquirrels can eſcape him; he lies in wait for ſtags, goats, hares, &c. and darts ſuddenly upon them.

The Catus, or cat, wild, and domeſtic. The cat in its ſavage ſtate is three or four times as large as the houſe cat; the head larger, and the face flatter. The teeth and claws are tremendous: its muſcles very ſtrong, as being formed for rapine: the tail is of a moderate length, but very thick, marked with alternate bars of black and white, the end always black: the hips and hind part of the lower joints of the leg, are always black: the fur is very ſoft and fine. The general colour of theſe animals is of a yellowiſh white, mixed with a deep grey: theſe colours, though they appear at firſt ſight confuſedly blended together, yet on a cloſe inſpection will be found to be diſpoſed like the ſtreaks on the ſkin of the tiger, pointing from the back downwards, riſing from a black liſt that runs from the head along the middle of the back to the tail. The tame or domeſtic cat is ſo well known, that it does not require deſcription.

The cat is found in almoſt every country in the world; and all the varieties in their appearance may be reaſonably enough attributed to the climates which produce them. The cat of Angora, is a variety with long hair, of a ſilvery whiteneſs, and ſilky texture; very long, eſpecially about the neck, where it forms a fine ruff: the hair on the tail very long and ſpreading: it is a large variety, found about Angora, the ſame country which produces the fine haired goat. It degenerates after the firſt generation in this climate.

FELLING *of Timber*. Many circumſtances are well known and conſtantly obſerved in the felling of timber for building, which, though to a haſty obſerver they might appear trifling, yet prove, on experience, to be of the utmoſt conſequence. One thing obſerved by Mr. De Buffon, which very greatly increaſes the ſolidity and ſtrength of timber, is, that the trees intended to be felled for ſervice ſhould firſt be ſtripped of their bark, and ſuffered to ſtand and die upon the ſpot before the cutting. The ſappy part or blea of the oak, becomes by this means as hard and firm as the heart; and the real ſtrength and denſity of the wood has been proved, by many experiments, to be greatly increaſed by it: nor is this a practice of any detriment to the proprietor, ſince the remaining ſtumps of theſe trees ſend up their young ſhoots as vigorouſly as if they had been cut down in their natural condition.

When any tree is to be cut down for timber, the firſt thing to be taken care of is a ſkilful diſbranching of ſuch limbs as may endanger in its fall; many trees are utterly ſpoiled for want of a previous care of this kind. In arms of timber that are very great, it is always neceſſary to chope or ſink in them cloſe to the bole, and then, meeting it with downright ſtrokes, it will be ſevered from the tree without ſplitting. In felling the tree, take care always to cut it as cloſe to the ground as poſſible, unleſs it is intended to be grubbed up: and the doing that is of advantage both to the timber, and to the wood; for timber is never ſo much valued, if it be known to grow of old ſtocks.

FELLOWSHIP, *Company*, or *Partnerſhip*, in arithmetic, is a rule of great uſe in balancing accounts amongſt merchants, and owners of ſhips; where a number of perſons putting together a general ſtock, it is required to give every one his proportional ſhare of loſs, or gain. See Syſtem of ARITMETIC, Article XIV.

FELO *de ſe*, is he that commits felony, by willingly and deliberately killing himſelf. See SELF-*Murder*.

FELONY, in common law, any capital offence, perpetrated with an evil intention. Though capital puniſhment does by no means enter into the true idea and definition of felony, the true criterion of which is forfeiture; for in all felonies which are puniſhable with death, the offender loſes all his lands in fee-ſimple, and alſo all his goods and chattels; but in ſuch as are not ſo puniſhable, his goods and chattels only. In a ſtricter ſenſe, felony denotes all capital crimes below treaſon. Felony includes ſeveral ſpecies of crimes, whoſe puniſhment is the ſame, viz. death; ſuch as petit-treaſon, murder, theft, homicide, ſodomy, rape, wilful burning of houſes, receiving of ſtolen goods; breach of priſon, reſcue and eſcape, after one is arreſted or impriſoned for felony, and divers others found in the ſtatutes, which are daily making crimes felony, that were not ſo before. Felony by the common law is againſt the life of a man, as murder, manſlaughter, felo de ſe, ſe defendendo, &c. againſt a man's goods, ſuch as larceny and robbery; againſt his habitation, as arſon and burglary; and againſt public juſtice, or breach of priſon. Piracy, robbery, or murder upon the ſeas, are felonies puniſhable by the civil law, and alſo by ſtatute.

Felony is eaſily diſtinguiſhed from treaſon. From leſſer crimes it is diſtinguiſhed by this, that its puniſhment is death, though not univerſally; for petty-larceny, i. e. ſtealing of a thing under the value of twelve-pence, is felony, according to Brook, though the crime be not capital, but only a loſs of goods. The reaſon Brook gives for its being felony is that the indictment runs, *felonice capit.*

FELT, a kind of ſtuff, either of wool alone, or of wool and hair; neither ſpun, croſſed, nor woven, but deriving all its conſiſtence from its being wrought, and fulled with lees and ſize, and afterwards faſhioned on a block or mould, by help of fire and water. Caſtors, camels, and coneys hair, lambs, and ſheeps wool, &c. are the moſt uſual ingredients of felts; and hats of all kinds are the works they are chiefly employed in. The felt intended for a hat, being ſufficiently fulled, and prepared, is reduced into one piece, ſomewhat in the figure of a large funnel; in which ſtate it remains ready to be put into form, and become a hat.

FEMALE, FÆMINA, a term peculiar to animals, ſignifying that ſex which conceives and generates its young within itſelf. See SEX and GENERATION.

FEMALE is alſo applied, figuratively, to things without life, from the reſemblance they bear to the females of animals. Thus we ſay: *Female-ſcrew*, *female-flower*, *female-plant*.

FEMININE, or FOEMININE, in grammar, one of the genders of nouns. The feminine gender is that which denotes the noun or name to belong to a female. In the Latin, the *feminine* gender is formed of the maſculine, by altering its termination, particularly by changing *us* into *a*. Thus, of the maſculine *bonus equus*, *a good horſe*, is formed the *feminine*, *bona equa*, *a good mare*; ſo, of *parvus homo*, *a little man*, is formed *parva fæmina*, *a little woman*, &c. In French the *feminine* gender is expreſſed, not by a different termination, but a different article: thus, *le* is joined to a male, and *la* to a female.

In Engliſh, we are generally more ſtrict, and expreſs the difference of ſex, not by different terminations, nor by different particles, but different words; as *boar* and *ſow*, *boy* and *girl*, *brother* and *ſiſter*, &c. though ſometimes the *feminine* is formed by varying the termination of the male into *eſs*; as in *abbot*, *abbeſs*, &c.

FEMME *Covert*, in law, a married woman. See COVERTURE.

FEMME *Sole*, an unmarried woman, whoſe debts, contracted before marriage, become thoſe of her huſband after it. A femme ſole merchant, is where a woman, in London, ſues a trade alone, without her huſband; on which account ſhe ſhall be charged without him.

FEMUR, or OS FEMORIS, in anatomy the thigh-bone. See Syſtem of ANATOMY, for deſcription Part II. for repreſentation ſee Plate of OSTEOLOGY *Fig.* 1. letter *a*.

FEN, a kind of wet land, or rather moraſs. Fens are of two ſorts: the firſt of a boggy conſiſtence, compoſed of water and earth intermixed; ſcarce firm enough to ſuſtain the tread of a man. See DRAINING, Sect. XIX. Syſtem of *Agriculture*.

FENCE, in agriculture, is a hedge, ditch, walk, or bank, made round fields, woods, gardens, &c.

FENCING, the art of making a proper uſe of the ſword; as well for attacking the enemy as for ſelf-defence.

TREATISE ON THE ART OF FENCING.

WHEN the Goths had introduced the cuſtom of ſingle combat, the art of defence became a neceſſary ſtudy: it was confined to certain rules, and academies were inſtituted to train up youth in the practice of them. Of late years it has been highly eſteemed throughout Europe; and to ſuch a degree of eminence has it attained in the Eaſt Indies, that Pyrard aſſures us none but princes and noblemen are allowed to teach it. They wear a badge of cognizance on their right arms, called in their language *eſaru*; which is put on with great ceremony, like the badges of our orders of knighthood, by the kings themſelves. This accompliſhment is now in higher repute in England than ever; where it is univerſally admitted an eſſential part of polite education, and a generous ardour prevails amongſt the youth of the higheſt rank, to excel in the cultivation of it.

Notwithſtanding the prejudices which ſome have imbibed againſt it, liberal minds can never view it in a diſadvantageous light, but on the contrary, when the many advantages to be derived from it are duly conſidered, muſt eſteem the theory and practice of it objects worthy their purſuit. It produces an eaſy and graceful deportment, a bold and martial air; and inſpires a manly confidence and animation. Every exerciſe in general has it's advantages, and concurs in accompliſhing one general effect. But none can give elegance and freedom in a greater degree than that of fencing, becauſe in it every part of the body is continually in action, and to crown all, it brings and confirms health, the moſt invaluable bleſſing of life. It alſo enables thoſe who practice it to purſue other exerciſes with greater facility. Though the cuſtom of deciding points of honour is not ſo frequent in this country, as in moſt foreign parts, men of faſhion, ſoldiers, and travellers of every denomination, find many advantages from the cultivation and acquiſition of this art, particularly in foreign countries, where the horrid practices of aſſaſſination are frequently committed. In fine, it has, among many others, two inſeparable qualities, the agreeable and the uſeful; the former, as it affords gentlemen a manly and diſtinguiſhed amuſement: the latter, as it forms their body, and furniſhes them with the faculty of defence, whether it be of their honour or their life, when the one or the other is brought into queſtion by any diſagreeable accident, or attacked by thoſe turbulent and dangerous perſons, whoſe correction is of ſervice to ſociety in general.

Mr. M'Arthur, author of a Treatiſe on the Theory and Practice of Fencing, regrets that a method is not adopted in our royal navy (to which that gentleman belongs) of exerciſing the ſhip's company of frigates, and ſuch ſmall veſſels of war as are liable to be boarded with ſimple Fencing, in the ſtile of broad-ſword play; as it would be of the utmoſt utility in the offenſive and defenſive attacks of boarding. He adds, that this might eaſily be accompliſhed by making it a branch of the duties of a maſter at arms, qualified to exerciſe the crew, or ſuch of them as might be allotted for boarding, in the rudiments of the art, and from the ſpirit of emulation prevailing among them, they would ſoon make themſelves proficients by a little practice.

To acquire a proficiency in any art or ſcience, a competent knowledge of theory muſt be judiciouſly applied to practice. Hence a theory, founded on juſt principles, digeſted and combined by practical experience, is neceſſary to the attainment of the art of fencing, as well as every other military art and ſcience.

In forming this Treatiſe, we have in general adopted the plan of Mr. Angelo from the reputation he has ſo juſtly acquired in the art, to which the French Encyclopædia bears teſtimony in the following words, under the article ESCRIME (*Fencing*).

"This article is entirely taken out of a Treatiſe publiſhed in
" London, by Mr. ANGELO; we are indebted to him both for
" the diſcourſes and plates. Had we known of any work more
" perfect in it's kind, we ſhould have made uſe of it."

Since the publication of Mr. Angelo's work, Mr. Olivier has introduced a new treatiſe on the ſubject, in which he has pointed out ſeveral novel remarks to ſimplify the practice of the Art: we have therefore made ſuch extracts from Mr. Olivier, as we preſume will conduce to render the Treatiſe more compleat.

How to hold the Sword.

Mr. Olivier obſerves, that in order to hold the ſword well, the hilt muſt be flat in the hand, the thumb ſtretched at an inch from the ſhell, the pummel under the wriſt. The ſword ſhould never be kept faſt in the hand but to parry or thruſt. For if it is always held with ſtrength, the muſcle of the thumb will ſoon grow ſtiff.

Method and effectual Means to render a Fencer active and firm on his Legs, and to ſhew him how to recover after the Delivery of a Thruſt, either Carte, or Tierce.

You ought to practice not only to make your thruſts with great quickneſs and vivacity, but alſo to deliver them with an elaſtic diſengagement and diſpoſition; and the motion of the body ſhould appear like divers ſprings throughout the whole frame. It is very eſſential to recover from your thruſts in the ſame lively manner, to enable you to parry in caſe of a return, or repoſte. To this effect, as ſoon as the ſcholar is able to thruſt with firmneſs of body and legs, inſtead of coming to his regular guard, he muſt carry his right foot to the left, and alſo the left to the right; and, in order that the ſcholar execute this well, the fencing maſter is to give his aſſiſtance for that purpoſe, till he is able to execute the ſame with eaſe himſelf. The carte ſhould be thruſt without the aſſiſtance of the plaſtroon, and, inſtead of recovering to your natural guard, you ſhould, with great agility and eaſe, carry the point of your right foot to your left heel, keeping your body erect, the head alſo, and the knees ſtrait. The ſecond motion is the moſt difficult: you muſt, after having made your thruſt in tierce, inſtead of the uſual recovery to your guard, carry the point of your left foot before the right, your left heel to your right toe. This ſhould be done with great eaſe and lightneſs, to bring you immediately on your legs: and it will enable you to come to a guard, by carrying the right foot forward, or the left foot back. You muſt obſerve, in either of theſe laſt motions, to move but one leg. The maſter, in order to aſſiſt his ſcholar when he is on the longe, ſhould keep up his right, with his left hand, till he brings him to a firm poſition of body and legs; this will facilitate his recovery to a guard with eaſe and quickneſs, and will diſpoſe him to the motions of the paſſes which are to be made, and of which we ſhall hereafter give an explanation. The beat on the ſword is done by engaging the blade either in tierce or in carte, or carte over the arm; you muſt leave the blade about four inches, and beat on it in a ſmart and lively manner, and thruſt firm, and ſtrait to the body. The appel, or attack, is made by raiſing the foot above two inches from the ground, ſetting it ſmartly down again, and thurſting directly at the body. The ſliding, or glizade, on the blade, is done by firmly engaging the ſword, bending the elbow, and raiſing the point, to gain the adverſary's feeble; bringing your wriſt about a foot forward, to put by his point, by a preſs on his blade, and a thruſt firm and ſtrait to the body. The ſimple diſengage is done when you are engaged in tierce or carte, by quitting the blade to the reverſe ſide, without touching it, and thruſting ſtrait to the body. The diſengage with the beat of the foot is done at once, and the ſame time you diſengage you muſt join the blade of the adverſary, make your attack, and thruſt ſtrait forward to the body. You muſt obſerve that theſe three different motions, viz. the diſengage, the attack, and the thruſt, ſhould be executed as quick as you may ſay—one, two.

The Salute in Fencing.

The ſalute is an uſage eſtabliſhed in all the fencing ſchools, in order to preſerve the politeneſs that we owe to one another. When you have drawn your ſword, put yourſelf in guard on tierce. Make two appels with the right foot. Bring your left hand to your hat and take it off with a grace. Afterwards paſs your right foot behind the left as far as the buckle; raiſe your right hand above the head, ſtretching your arm and turning the nails well upward. Let the hand that holds the hat be ſtretched along the flank, at the ſame time you paſs your foot and raiſe the right hand. Make two other appels with the right foot. Bring your left foot again by the buckle of the right, covering your head directly, put yourſelf on your firſt guard. Let all theſe motions be well joined to one another, and be made with grace, nobleneſs, and eaſe. The ſalute before you puſh tierce and carte (or to thruſt at the wall) is moſt uſed; for you muſt never fence with any one without doing it. Being in guard on the outſide, make a round with the wriſt, preſenting your body uncovered to your adverſary; then make him the compliment of thruſting firſt at you. If you are to puſh firſt, longe out as if you were to thruſt carte, preſenting the point of your foil at a little diſtance from your antagoniſt's body. Afterwards recover, bringing the right heel by the other, both hams well ſtretched; and ſalute in carte and in tierce, as aforeſaid, and then forming a ſmall circle with the wriſt, put yourſelf on guard.

Of the Simple Parades.

Each thruſt hath its parry, and each parry its return. To be a good fencer, it will not be ſufficient to ſtand gracefully on your guard, nor even to thruſt with great ſwiftneſs and exactneſs; the chief point is to be well ſkilled in the defenſive part, and to know how to parry all the thruſts that ſhall be attempted to be made at you. When you are compleat in the defenſive part, you will ſoon be able to tire your adverſary, and often find an opening to plant a thruſt. You ſhould apply yourſelf to make your parades cloſe, and firm in the line, by holding your ſword light, from the gripe to the point. The body ſhould be profile, or ſingled out to the left ſide: and the wriſt and the elbow ſhould be the chief actors.

Poſition for the Guard in Carte.

In order to acquire this poſition, the left knee muſt be bent, and at two feet diſtance from the right; the left heel in a ſtraight line with the right heel, and the point of the foot perpendicular to the knee: you muſt obſerve that the bend on the left ſide ſhould not in the leaſt take off from that eaſe with which the body ought to be ſupported; and, to render yourſelf firm, bend the right knee a little, but not too much, for, if it is too much bent, the body might fall forward, and if not bent at all, neither the thigh, nor the leg, would be flexible, and you would, conſequently, not have ſufficient elaſticity nor ſtrength to longe, nor agility to advance or retire. The Guard in carte is the moſt advantageous, and the moſt elegant poſition in Fencing.

To get within, or without Diſtance.

In order to come to our former poſition of the guard, it is very neceſſary to know what is meant by diſtance. To get within diſtance, is called advancing on the adverſary, when he is at too great a diſtance from the point of your ſword; to be without diſtance, is to retire when your adverſary's point is too near. To get within diſtance, of your adverſary without altering the regular poſition of your Guard, you muſt raiſe your right foot juſt above the ground, and carry it about a foot forward, in a ſtrait line with your left heel, bending your knee a little, and at the ſetting down of the foot, you muſt follow with the left leg in the ſame manner and diſtance keeping your left leg well bent, to ſupport the body entirely on that ſide. To get out of diſtance you muſt retire with the left foot, and follow regularly with the right foot, keeping always two feet diſtance (more or leſs according to your ſize) from one heel to another: you muſt be very cautious not to loſe your perpendicular poſition of body and guard, elſe, by the diſorder which your adverſary could cauſe in your legs, the body would no more be firm, neither would the wriſt be able to execute with advantage when occaſion ſhould require it.

Poſition for the Guard in Tierce.

To execute the tierce (as before mentioned) your nails muſt be downward, and engaging your adverſary's ſword, touch his blade; you muſt engage your point from inſide to outſide, by changing the poſition of your wriſt; ſo that when your wriſt is turned in carte, on the inſide of your adverſary's blade, you muſt, by a motion of the wriſt, drop your point cloſe to his blade, turning your nails downwards; which is diſengaging from carte to tierce. Being in tierce, you muſt likewiſe drop your point, turning your wriſt with your nails upward, and cloſe your adverſary's blade; which is diſengaging from tierce to carte. You muſt make frequent diſengagements in this manner, in a firm poſition, till your adverſary retires, at which time you muſt diſengage, and advancing, cloſe his blade, with your point in a line to his body, always ſteady on your guard. When you have thus diſengaged, and advanced on your adverſary, in theſe two poſitions, you muſt retire, and every time he diſengages, you muſt turn your wriſt on the ſide you are engaged; this will teach you to compleat your parades, in which the wriſt is only to act: you muſt always oppoſe your adverſary's ſword ſufficiently to cover the ſide he attacks, and you muſt nevertheleſs obſerve, that, when you cover one ſide, you do not uncover the other ſide or the lower parts.

Poſition for the Inſide Guard called Carte, and the Inſide Thruſt, called the Thruſt in Carte. Figure 1. Plate I.

To execute this thruſt well, three motions of the wriſt are to be made at once; which are, to turn the wriſt and nails upward, raiſe the wriſt, and oppoſe; and in theſe motions the arm ſhould be ſtraitened, and the wriſt raiſed above the head, and the point dropt in a line to the adverſary's breaſt; being thus ſituated, you muſt throw your wriſt forward, ſtepping immediately, or longe about two feet beyond your guard; the left heel, and knee, ſhould be in a perpendicular line, the point of the foot in a line to the knee, and the right heel in a line to the left; the left foot ſhould be plumb to the ground, and not move, heel or toe. And obſerve, that when the arm ſtretches forth in order to thruſt, the foot muſt follow at the ſame time; the body ſhould be very upright, the left leg ſtretched, and the left hand ſhould hang down in a line with the left thigh, about one foot diſtance, with the hand open, nails downward, and fingers cloſe. Obſerve well, that the body be firm, the head kept up, the left ſide from the hip well turned in, the ſhoulder eaſy, and the wriſt oppoſed to the ſword; that the pummel be directed in a line with your left temple, to prevent a counter thruſt from the adverſary's inſide, which will certainly happen without this oppoſition. The thruſt being made, the recovery to the guard muſt immediately follow, with the ſword in a ſtrait line with the adverſary's body. You cannot practice this thruſt too much, it being the moſt eſſential and the moſt ſhining one that is made in fencing.

Poſition for the outſide Guard called Tierce, and the Thruſt in Tierce. Figure 13. Plate II.

To deliver this thruſt, your wriſt muſt be turned with the nails downward, aud in the ſame height as in carte; the head muſt be covered by the oppoſition of the wriſt, though not in a line with the face; the inſide of the arm in a line with the right temple, the left arm to fall down about a foot from the thigh, the nails upward. Obſerve, that at all times when the right arm is turned with your nails down, that the left ſhould be the ſame, and at the ſame diſtance from the thigh as in carte.

Poſition for the outſide Guard, called Tierce, and the Thruſt on the ſame Side, with the Wriſt reverſed in Carte, called Carte over the Arm. Figure 2. Plate I.

This thruſt muſt be delivered on the outſide of the adverſary's ſword, with the nails upwards as in carte, but in the tierce line, plunging the point to the adverſary's body; the wriſt ſhould be ſtrait, neither inclined to the outſide or the inſide, but raiſed, that the wriſt and pummel may come in a line with your right temple, the thumb and nails, and the flat of your blade in one line, and the other parts in the ſame poſition as in the thruſt in carte.

Poſition of the Outſide Guard called Tierce, and the Thruſt from the Outſide under the Wriſt, called Seconde. Figure 3. Plate I.

This thruſt doth not differ from the tierce; but, becauſe it is delivered under the wriſt quite along the elbow, therefore the adverſary's ſword ſhould be engaged in tierce, dropping the point with the wriſt in tierce, directing it between the adverſary's arm-pit and his right breaſt; here the body ſhould be more bent forward, than what is mentioned in the former thruſts.

Poſition of the Inſide Guard called Carte, and of the Thruſt under the Wriſt on the ſame Side, called Low Carte. Figure 14. Plate II.

To deliver this thruſt well, you muſt engage the adverſary's ſword in carte, dropping your point under his wriſt, in a line to his elbow, and in thruſting, not only fix your point in his flank, but ſtrait traverſe the line about a foot outward, without turning the foot to the right or to the left: forming an angle from the wriſt to the blade, the body as much bent as in the thruſt called Seconde, and the hand as much raiſed as in the carte thruſt: by this manner the oppoſition will be formed to cover the body and the face.

Poſition of the Inſide Carte, called Carte, and the Thruſt given on the outſide Flank, called Flanconade. Figure 4. Plate I.

To execute this thruſt well, the ſword of the adverſary muſt be engaged in carte, the point fixed in the flank of the adverſary, and, binding his blade, carried behind his wriſt, under his elbow. In this operation you muſt gain his feeble, and, without quitting his blade, plunge your point under his elbow to his flank, your wriſt turned nails upward, forming an angle from the wriſt to the point. In the execution of your thruſt, obſerve alſo, that the left hand ſhould drop under the right, and that too, form an angle, from the left elbow to the wriſt, with your hand open, to prevent being hit on the parade of this thruſt, by the adverſary's turning his wriſt in tierce, and by thus reverſing his edge he would throw the point on you. In the defenſive part of this parade we ſhall explain this oppoſition.

Of the Inſide Parade, called Carte, and the Thruſt in Carte. Figure 5. Plate I.

This parade of carte within the blade, is made by a dry beat on the adverſary's blade, with the fort of your blade, and your inſide edge. You muſt throw your body back in a ſtrait line with his, and let your oppoſition to his blade be about four inches wide to the left; your arm ſhould be a little contracted, and the moment you have parried preſent your point firm in a line to his breaſt, to enable you to make a return, or repoſte, quickly.

Of the Outſide Parade, called Tierce, and the Tierce Thruſt, called the Outſide Thruſt. Figure 6. Plate I.

This outſide thruſt, called tierce, is parried by the inſide edge, and the turning of the wriſt to an outſide with a ſtretched arm, oppoſing the blade with the wriſt; without leaving the ſtrait line, you muſt lower your point towards the adverſary's body, to enable you to return the thruſt on the ſame ſide. You muſt alſo parry this thruſt, by bending your arm, and oppoſing your wriſt, and by keeping your point to your adverſary's right ſhoulder. By this means you will be able to return the thruſt under his wriſt, called the thruſt in ſeconde.

Of the Outward Thruſt, with the Nails upward, commonly called the Feather Parade, againſt the Outward Thruſt, Nails upward, called the Carte over the Arm. Figure 15. Plate II.

In order to parry this thruſt on the outſide of your blade, you muſt oppoſe with your outward edge, the wriſt as in carte, nails upward, and your wriſt in a line with your right ſhoulder, and, with a ſtrait arm, oppoſe the adverſary's blade with the heel, or forte of your ſword. This thruſt may be parried alſo, by drawing in your arm, holding your wriſt a little outward, with your point raiſed; which being done, you muſt ſlide, and preſs from the feeble to the forte of his blade, by which you will not only put by his point, but have a great chance to fling his ſword out of his hand.

Of the Outſide Parade, for the Thruſt under the Wriſt, called the Thruſt in Seconde. Figure 7. Plate I.

You muſt parry this thruſt with the inſide edge, and raiſe your wriſt, in ſeconde, to the height of your right ſhoulder, your point low, and well maintained from forte to feeble, directing your point between the arm pit and right breaſt of the adverſary; and alſo keep a ſtrait arm, in order to throw off his point.

Of the Half Circle Parade, or the Parry againſt the Inſide Thruſt under the Wriſt, called the Low Carte. Figure 16. Pate II.

This parry of the half circle ſhould be made within the ſword, by a ſmart beat on the feeble of the adverſary's blade with your inſide edge; your nails muſt be upward, your arm ſtrait, your wriſt raiſed to the height of your chin, and the point low, but well oppoſed from forte to feeble.

Of the Parade againſt the Binding of the Sword, from the Inſide, to Thruſt in the Flank, called Flanconade; by reverſing the Edge of the Sword to an Outſide, called Cavez; and an Explanation of another Parade for the ſame Thruſt, by binding the Sword. Figure 8. Plate I.

The reverſing the edge from an inſide to an outſide, called cavé, is a parade where you muſt, with great ſwiftneſs, turn your inſide edge to an outſide, at the very time the adverſary gains your feeble, by his binding, to direct his point in your flank, called flanconade, you muſt form an angle from your wriſt to your point, by which you will throw off the thruſt, and the point of your ſword will be in a line to the adverſary. You muſt keep a ſtrait arm, and maintain, with firmneſs, your blade, from fort to feeble. The ſecond parade mentioned, called the binding of the blade, is made at the time the adverſary attempts to thruſt his flanconade. In order to this, you muſt yield your point, and

ſuffer your feeble to be taken, ſo as to let your point paſs under his wriſt, without quitting his blade in the leaſt, that your ſword may form a demi-circle; and, gathering his blade in carte, you will find that the two ſwords, and wriſts, are in the ſame poſition as when the attack began, with only this difference, that the wriſts will be a little lower than in the ordinary guard.

Of the Parade called Prime, derived from the Broad Sword, and called the St. George Guard, againſt the Outſide Thruſt under the Wriſt, called Seconde. Figure 9. Plate I.

In order to parry this outſide thruſt under the wriſt, called ſeconde, with this prime parade, you muſt, at the time your adverſary thruſts under the wriſt, paſs your point over his blade, and lower it to the waiſt, keeping your wriſt as high as your mouth, turning your nails downward, your elbow bent, your body kept back as much as poſſible, and give an abrupt cloſe beat on his blade with your outward edge; as you are then ſituated, you may, by way of precaution, hang down your left hand, as before mentioned in the flanconade, and in the ſame manner, or ſtep out of the line. This oppoſition is made at the time you parry, and very cloſe, to avoid the adverſary's point, if you ſhould want to thruſt in a ſtrait line. To ſtep out of the line, muſt be done at the time you parry the thruſt, by carrying your right foot, flat and plump, about ſix inches out of the line to the right, the left foot alſo to be carried to the ſame line about a foot, which will throw you further from the centre.

Of the Parade called Quinte, the Point low, and Wriſt raiſed, againſt the Outſide Thruſt under the Wriſt, called Quinte Thruſt. Figure 10. Plate I.

The thruſt in quinte is made by making a feint on the half circle parade, having your wriſt in carte. You muſt diſengage your point over the adverſary's blade, at the time he parries with the half circle, or prime parade, and thruſt directly at his flank. This thruſt is parried by holding your wriſt in high carte, with a low point and by oppoſing from the forte of your outſide edge, to put by the adverſary's point; by a wriſt well maintained from forte to feeble, and a very ſtrait arm, having the body entirely ſupported by the left hip.

An Explanation of the various Thruſts that may be parried with the following Parades.

All parades are made in general in the advance, the retreat, or by ſtanding your ground. With the carte, by holding your wriſt low, you parry the low carte and the ſeconde; by raiſing your wriſt, you parry all the cuts over the point on the inſide of the ſword and the flanconade. With the tierce you parry the carte over the arm; in raiſing your wriſt, you parry the cuts over the arm, carte over the arm or tierce. With the feather parade, that is, with your outward edge when your wriſt is turned in carte on the tierce line, you parry the tierce thruſt; in raiſing your wriſt, you parry the cuts over the point on that ſide. With the parade of ſeconde, you parry all the lower thruſts, both inſide and outſide; ſuch as low carte, ſeconde and flanconade. With the half circle parade, you parry carte, tierce, carte over the arm and ſeconde. With the prime parade, you parry carte, low carte, and ſeconde. With the quinte parade, you parry ſeconde and flanconade.

Obſervations on the Parades in general.

A good parade is as neceſſary and uſeful when well executed, as it is dangerous and fatal if done without judgment, and made wide and rambling. To parry well, will prevent your being hit; therefore you ſhould obſerve, when you are defending the place in which you are attacked, that you do not give an opening on the contrary ſide, which would give more eaſe to your adverſary to throw in a thruſt; for which reaſon you ſhould not flutter, or ſhew the leaſt concern, by any motion he may make, either with the body, his foot, or the point of his ſword. There is not the leaſt doubt but you have a great advantage in forcing your adverſary to be on the defenſive, becauſe at this time it will be impoſſible for him to attack; and by this you will certainly find your account, by the openings he may through ignorance, or inadvertency give. And it is alſo very certain, that, by being able to baffle his attacks, by a cloſe parade, your repoſtes, or returns, will be ſafe and quick, and according to the rules of fencing.

Of the Return, or Repoſte, after the Parry.

Every parry hath its return; you will be reckoned a good fencer, when you parry with judgment, and return with a lively exactneſs. There are in fencing two ways of returning a thruſt; the one is, when the adverſary thruſts; and the other, when he is on his recovery to his guard. The firſt of theſe is for thoſe only who are well ſkilled in this exerciſe, becauſe it requires a moſt exact preciſion, a quick ſight, and a deciſive parade; ſince the adverſary ought to receive the thruſt, before he has finiſhed and executed his; which is termed, in fencing, a return from the wriſt. The ſecond, which is on the adverſary's recovery to his guard, is done by hitting him before he has ſet his right foot to the ground again, thruſting out with great celerity and reſolution, in order to execute well. The return, called the return of the wriſt, ſhould hit the adverſary at the very time he longes out to thruſt. This method muſt be executed with the greateſt quickneſs poſſible. In order to ſucceed, you muſt be firm on your legs, and, after having parried with the fort of your ſword, in a dry and abrupt manner, you muſt ſtraiten your arm, and bring your body a little forward on the right leg, remarking, attentively, that your wriſt direct your point to the adverſary's body; as you may obſerve in Figure 12. Plate I. Figure 17. and 18. Plate II.

Of the Return in Carte, after the Carte Parry. Figure 11. Plate I.

At the very time the adverſary delivers his carte thruſt, you muſt parry with the heel of your blade, and inſtantly return the thruſt within the ſword, and return to your guard as quick, according to the rules already explained. If the adverſary ſhould in the leaſt raiſe his wriſt on his recovery, you may return a low carte, and recover with your wriſt in tierce, or demi-circle.

Of the Return in Tierce, after the Tierce Thruſt. Figure 12. Plate I.

At the time that you parry the tierce with a ſtrait arm, and your point a little lowered to the adverſary's body, you muſt return the ſame thruſt, only your wriſt a little inclined to the outſide. Take great care that the hand moves firſt, and oppoſe his blade well, from feeble to fort; recover to your guard in prime, or demi-circle parade. You may alſo, after your tierce parry, return the thruſt in ſeconde, and recover in ſeconde, demi-circle, or in tierce.

Of the Return in Seconde, after having parried Carte over the Arm. Figure 17. Plate II.

After your parry carte over the arm, you may return the ſame thruſt, by holding your wriſt nails upward, thruſting and oppoſing with your outward edge, and plunging your point to his body, with your recovery to a half-circle parade. If you ſhould return a ſeconde thruſt, you ſhould, the moment you have parried carte over the arm, drop your point along the outſide of his wriſt and elbow. This return is eaſier to be made than the aforementioned; your recovery is a half-circle, ſeconde or tierce.

Of the Return in Quinte, after the Thruſt in Seconde. Figure 18. Plate II.

Having parried the thruſt in ſeconde with the quinte parade, you muſt return the thruſt without altering your wriſt. If you parry with the parade in ſeconde, you muſt return in ſeconde, recover ſwiftly with your wriſt in ſeconde, and bind the blade in carte, after the recovery, without leaving it.

Of the Return on the Flanconade Thruſt, by reſerving the Edge to thoſe who have not the Precaution to oppoſe with the Left Hand. Figure 19. Plate II.

At the time the adverſary thruſts the flanconade, you muſt parry, by raiſing and turning your wriſt in tierce, without leaving his blade, forming an angle from wriſt to point, ſteadily directed to his body. In this return there is no occaſion to thruſt out the right leg; you muſt only bring your body forward, and ſtretch out your left leg. The angle which is formed in turning the wriſt is quite ſufficient to keep off and return the thruſt; this done, you muſt recover your guard in prime, or half circle. If you parry the flanconade, by binding the ſword, as we have before mentioned, you may return the thruſt ſtrait in carte; and if, on the adverſary's recovery, he ſhould in the leaſt drop his point, you may return a flanconade; if, on the contrary, he ſhould raiſe his wriſt or his point, you muſt return a low carte, and recover by a circle, joining his blade.

Of the Return from the Prime Parade, to the Seconde and Low Carte Thruſts. Figure 20. Plate II.

As ſoon as you have parried the ſeconde, or the low carte thruſts with the prime parade; ſtepping out of the line with the right foot (as explained in the parades thereof) you muſt return the thruſt in prime, holding your wriſt in a line with your left ſhoulder; by this means you will form an oppoſition which will cover your body and face; after which you muſt recover in the ſame poſition of prime, or in the half circle.

Of the Parade by a Counter Diſengage.

This parade is made at the time the adverſary delivers his thruſt, by diſengaging carte or tierce, or carte over the arm: therefore, to execute this parade well, you muſt, the moment he diſengages to thruſt, diſengage alſo, very cloſely to his blade, and, having formed your parade, which ought to be done with the greateſt preciſion and quickneſs that is poſſible, ſupport your blade from fort to feeble.

Obſervation on this Parade.

As a quick wriſt and a light point might eaſily deceive this laſt counter diſengage; that is to ſay, if the adverſary ſhould continue his diſengages often, and quicker than you can follow him, in ſuch a caſe, to ſtop his career, you muſt have recourſe to the circle parade, which will certainly ſtop the progreſs of his point.

Of the Half Circle Parade.

This parade, which is the chief defenſive parade of the ſword, parries not only all the thruſts, but alſo obſtructs all the feints that can be made; and, to execute it well, you ſhould ſtraiten your arm, keep your wriſt in a line with your ſhoulder, your nails upward, and, by a cloſe and quick motion of the wriſt, the point ſhould form a circle from the right to the left, large enough to be under cover from the head to the knee; in this manner, by doubling your circle till you have found the adverſary's blade, your parade will be formed. And, now, in order to ſtop this circle parade, notwithſtanding its being redoubled with great vivacity, you may ſtop his blade ſhort, by keeping your wriſt the height of your ſhoulder, and lowering your point, as in the quinte parry; and, recovering, bind and gather his blade in carte. You ſhould exerciſe and practiſe theſe circle parades, from the counter diſengages to the circle, and from the circle to the counter diſengage. You may practice this leſſon yourſelf, either with ſword or foil: this will ſtrengthen and ſupple your wriſt, and will inſenſibly procure great eaſe and readineſs to defend yourſelf upon all occaſions.

Method of thruſting and parrying Tierce and Carte, called thruſting at the Wall.

It is called thruſting at the wall, becauſe the perſon who parries is not to move his body nor his legs from where he ſtands; it is only his wriſt which is to perform his parades. In order to execute this leſſon well, we ſhall explain the poſition in which he that parries is to ſtand. To parry at the wall, you muſt place yourſelf ſo that the left foot may not be able to ſtir further; you muſt ſingle your ſhoulder, hold your head erect, pull off your hat, and open with your right arm, ſo as to carry your point to the right, that your adverſary may take a proper meaſure, or diſtance, for his longe; after which you put on your hat, and carry your left hand back to the ſmall of your back, and giving an opening, either in tierce or carte, you muſt be ready to parry (in this attitude) with quickneſs, all the adverſary's thruſts.

To thruſt againſt the wall, you muſt place yourſelf ſtraight on your legs, and, coming to your guard, pull off your hat with a pleaſant countenance, and deliver a gentle thruſt in carte towards the adverſary, gently touching your button to his breaſt, to take your diſtance; you muſt then recover to your guard, and put your hat on, making, by way of ſalute, the two motions of the wriſt, in tierce and carte, being the uſual way. Thus, thruſting againſt the wall accuſtoms the ſcholar to thruſt with quickneſs, and to parry ſo likewiſe; it gives an exactneſs and eaſe, as well as a knowledge of diſtance, and is more uſeful, as in fencing with various perſons you will meet with people of different make and ſize.

Method how to thruſt at the Wall with Swiftneſs.

There are three different ways of thruſting at the wall. The firſt is, by engaging the fort of the adverſary's blade, and holding a looſe point, you muſt diſengage lightly, and thruſt ſtrait at his body, ſeeking his blade. The ſecond is, by engaging from the point to his blade, with a bent arm, diſengage, and thruſt ſtrait to the body; which is called thruſting from point to point. The third is, by delivering ſtrait thruſts to the inſide and to the outſide of the adverſary's body; in this latter you need neither engage the blade, nor diſengage. The Italian maſters make much uſe of this laſt, as it gives great ſwiftneſs, and uſes the wriſt to execute firſt, and alſo looſes the ſhoulder completely.

Rules to be obſerved in Thruſting at the Wall.

When you have taken your dimenſions or diſtance, as before mentioned, you ought in no way to ſtir your left foot, nor the body, make no motions or feints whatſoever, but thruſt according to rule, either inſide or outſide, by diſengagements, or by thruſting to the blade ſtraight forward; and if you make any feints it muſt be with the mutual conſent of each other.

Explanation of what is called Feints.

A feint is, to ſhew the appearance of a thruſt on one ſide, and execute it on the other. In this you ſhould lead the adverſary's wriſt ſo much aſtray as to obtain an opening ſufficient to throw in the thruſt you have premeditated. You muſt be very cautious not to uncover yourſelf in making a feint; for, inſtead of ſucceeding in your project, you will give the adverſary an opportunity of a wide opening, and induce him to throw in a ſtraight thruſt: therefore it is abſolutely neceſſary, in making a diſengage in order to feint, to oppoſe the fort of your blade, and, with great ſubtilty, make the motion of your point near enough to his fort, that you may the more eaſily hit him. All feints may be executed ſtanding ſtill, or in moving; you may make them after an appel, or attack of the foot, after a beat on the blade, or at the time the adverſary forces your blade; or at his diſengaging. You muſt obſerve that, when you feint, your wriſt is the height of your ſhoulder, your elbow a little bent, that your wriſt may be more flexible, and your point lighter. If you are engaged in carte, diſengage carte over the arm, near the adverſary's fort, bring your point back in its carte poſition, thruſt ſtraight forward, and recover to carte, or in the demi-circle. If engaged in carte over the arm, you muſt diſengage in carte, and thruſt carte over the arm, and recover in tierce, or in half circle; and if the thruſt is parried, you muſt treble the feint, and thruſt within the ſword. If engaged in tierce, you muſt mark your feint below the wriſt in ſeconde, thruſt in tierce, and recover to your ſword in ſeconde, or a half-circle. If engaged in tierce, you may alſo feint in carte, keeping your point in the adverſary's face, thruſt a low carte, and recover to the ſword by a circle. To feint on any diſengagement of the adverſary, you muſt force or lean on his blade a little, to oblige him to ſlip, or diſengage; and at that very time you muſt, with quickneſs and preciſion, feint on his motion, and thruſt ſtrait at him.

Defence or Parade againſt all Feints.

The ſureſt defence againſt feints, is to get at the adverſary's blade by a counter diſengage, or by a circle; for if you offer to ſeek the blade by a ſimple parade, it will be impoſſible to get at it, ſince he can redouble his feints at pleaſure; wherefore, by the parades, you immediately ſtop the adverſary's point, and you oblige him to change his intention and idea.

Obſervations on the Feints, and at what Time they are good and bad.

There are fencers who, when they feint, make large motions of their body, of their points, or violent attacks of the foot, in order to precipitate their adverſary's defence, thinking to take advantage of the large openings he may on ſuch occaſions give; all theſe attempts, which are falſe, cannot ſucceed againſt any but thoſe who are timid, and not ſtaunch in their guards; but, againſt a man who is ſkilful and cool, and who keeps his point cloſe in the line to his adverſary, and who ſeeks his blade with the wriſt cloſely, according to the rules of fencing, whatever motions may be made by feints will prove ineffectual. There are others who make feints by advancing their ſword, and when the parry is attempted, drawing and changing the point from its ſituation, thruſt out: theſe three motions are contradictions to each other, and are ſo ſlow, that, if the adverſary was to thruſt at the time they draw in, they would infallibly be hit before they had finiſhed their feint and intent. You ſhould, as much as poſſible, make all feints in proper diſtance, that you may be enabled to accompliſh your thruſt with ſwiftneſs. You may alſo make the feints out of diſtance; but you muſt continue them at the time you advance to get into diſtance, and change your idea, if the adverſary ſhould come to join your blade. You ought to cover yourſelf well in making theſe motions, for the adverſary might thruſt ſtraight forward at the time you advance, or ſtop your feint by any other motion. You are not always to hope or expect your feints ſhould be anſwered, for by this you may eaſily be baulked; but, knowing the adverſary has power to attack, and keeping yourſelf on your guard, you will be more ready to defend yourſelf. You will alſo be the more ſure that your feint will beſt ſucceed while the adverſary's wriſt is in motion; at that time ſeizing the opportunity to make your feint, he will become apt to fly to the defenſive with more irregularity; and not only will give openings, but you are ſure he cannot attack: and conſequently you will be apt to hit him with more eaſe, and without riſque.

Of the Motions made on the Blade ſtanding ſtill called Glizades, and the Glizade from Carte over the Arm, to Thruſt Carte.

If you are engaged in carte, and are in diſtance, you muſt have a flexible arm, your body ſingled, and entirely on the left hip; in this poſition you muſt make a beat on the adverſary's blade, with an intent to ſtir his wriſt; if he ſhould come to the ſword, you muſt diſengage lightly carte over the arm, with your wriſt high, and your point in a line to his face; and, the moment he cloſes the blade, diſengage in carte, and thruſt directly ſtrait. If, after this, he ſhould not return, but only force your blade, you may reiterate a ſecond thruſt, by turning your wriſt in tierce, on the blade, without leaving it, and recover to his ſword in carte.

Of the Glizade from Carte, to Thruſt Carte over the Arm.

If you are engaged in tierce, or carte over the arm, you muſt diſengage in carte, keeping your point forward in a line to the adverſary's body; at the ſame time make an attack with the foot, and when you find he forces your blade, ſlip, or diſengage quickly in carte over the arm, and thruſt out, and redouble the thruſt in ſeconde, recovering ſwiftly to the ſword in tierce, or in demi-circle.

Of the Glizade from Tierce, to thruſt the Seconde.

If you are engaged on the tierce ſide, after beating on the blade, and an appel, you muſt diſengage to tierce, with your point advanced to the enemy's face, and the moment he feels the blade, parry, either by tierce, or the wriſt turned in carte over the arm, you muſt drop your point under his wriſt, and thruſt ſeconde, recovering your ſword in tierce, or the half circle.

The binding and croſſing the Blade.

Very few maſters teach the croſſing of the blade; this operation is the more neceſſary, being not only uſeful to put the adverſary's blade by from the wriſt to the knee, but will often throw his ſword out of his hand. If he ſhould preſent himſelf in diſtance, having his arm ſtraight and his point alſo, you ſhould incline your body entirely on the left ſide, and engage his ſword in carte, turning your nails a little more upward than in the ordinary guard, and engage your fort about a foot from the feeble, directing your point to the left; in this poſition you muſt ſwiftly turn your wriſt in tierce, holding your ſword firm, and paſſing your point over his arm, without quitting his blade, ſtop your ſword from fort to point, holding your hand the height of your ſhoulder, and the point as low as his wriſt; this croſſing being made, thruſt out at full length in tierce, and recover your ſword by a circle.

The Manner to ſhun theſe Croſſings of the Sword.

As every thruſt has its defence, it is neceſſary we ſhould explain them in the cleareſt manner; there needs only a due attention, a quick eye, and judgment, to ſhun all thruſts. You muſt give way with your point by a diſengage to a ſtrait line, at the time the adverſary wants to croſs your blade; by this means, as he will find no blade, you will evade it. It might happen, even that when he finds no blade, and conſequently no reſiſtance to his blade, he may fling his own ſword away, inſtead of his adverſary's if he ſhould not maintain his point to the waiſt and hold it very faſt.

Of

Of the Beat on the Tierce Thruſt to fling down the Sword of the Adverſary.

If the adverſary ſhould make a full thruſt in tierce, you muſt diſengage nimbly in carte, have your body well on the left hip, and draw in your arm a little more than in the ordinary guard, with your point high: this done, before he recovers to his guard you muſt make a ſmart beat with your foot on his feeble; which will open his fingers and throw down his ſword.

Another Way to beat the Sword out of the Adverſary's Hand.

If the adverſary thruſts in tierce, you muſt parry with the prime parade; when parried, raiſe your point lightly to the left, and with the carte, or inſide edge of the fort of the blade, beat ſmartly and ſtrong on the feeble of his blade.

Of the Beat on the Sword in Carte over the Arm.

If the adverſary preſents himſelf, having his wriſt turned in carte, with a ſtraight arm, and his point in the ſame line, you ſhould make a cloſe feint toward his fort; if that ſhould not move his point, you muſt diſengage in carte over the arm, with your arm contracted, and your point high, and with the fort of your blade beat ſmartly on his feeble; ſtraighten your arm immediately, and thruſt firm and ſtraight carte over the arm. If his ſword does not drop by this beat, you will at leaſt find opening enough to throw in your thruſt; this done, recover quickly to your guard by the circle parade. To ſhun this beat you muſt, the moment you have made your thruſt, recover to the adverſary's blade by the circle parade; for this beat on the blade is only made uſe of againſt thoſe who, when they have thruſt either in tierce or carte, within or without the blade, do not recover immediately to their guard; or when they are in guard, keep their arm ſtraight, and the point of their ſword in a direct line with their arm. If the adverſary ſhould attempt to beat when you are firm on your legs, and in guard, you muſt ſlip his beat, and with ſubtilty hinder him from touching your blade, and at that very moment go on with your thruſt ſtraight forward.

Of the Plain Cut over the Point from Carte, in Tierce. Figure 21. Plate II.

After a thruſt made in carte, if your adverſary parries with the feeble of his ſword, you muſt, on your recovery, draw in your arm, keep a ſtraight blade from fort to point, and paſs it over his point; your wriſt being turned in tierce, you muſt raiſe it inſtantly, and plunging your point to his body, you muſt make a full thruſt in tierce, and recover to the ſword in the line. This cut over the point is alſo made after having parried a carte thruſt, if the adverſary is fearful of a return on that ſide, and therefore forces your blade in his recovery, you ſhould, in ſuch caſe, execute the cut over, ſmartly to an outſide, either in tierce or carte over the arm. You may alſo execute the ſame cut over the point, in carte over the arm, after you have made a carte thruſt, if the adverſary ſhould force your blade ſtanding on his guard. Obſerve well, that all theſe cuts over the point are not made uſe of but where the adverſary parries from the half ſword to the point, called the feeble, or when he forces your blade out of the line in the ſame manner.

Of the Plain Cut over the Point, from Tierce to Carte.

If you are engaged in tierce, you muſt make an attack with the foot, and execute a half thruſt to the ſword; and at the time the adverſary comes to this parade in tierce, you muſt draw in your arm, keeping a ſtraight point, and cut over his point in carte, your wriſt turned in carte, dropping your point a little, and make a full thruſt in carte; the thruſt made, recover ſtraight in a line to the adverſary's ſword, with an oppoſed wriſt, and your point to his body.

Cut over the Point from Tierce to Carte, to thruſt Carte over the Arm.

If you are engaged on the outſide of the ſword, turn your wriſt as in carte over the arm, attack ſmartly with the appel of the foot, and at the adverſary's coming to a parry, cut over the point to the inſide, with your wriſt high in carte, and your point ſtraight to his body, as if you intended to thruſt there; and as ſoon as he comes cloſe to your blade, diſengage lightly, and thruſt a full carte over the arm, by ſending your wriſt firſt, with a ſufficient oppoſition, as before mentioned in the rules of fencing; the thruſt made, recover to a guard with your ſword before you, and the point to the adverſary's body.

Of the Definition of the Wriſt, after the Thruſt made in Carte.

This definition of the wriſt is not made uſe of but to thoſe who do not return from the thruſts made at them, either to the inſide or outſide; to execute this, you muſt engage the adverſary's ſword in tierce, make an appel of the foot, and as ſoon as he cloſes your blade, diſengage lightly near his fort, and thruſt in carte; the moment your thruſt is made, ſeem to recover to a guard, by bringing up your right foot about a foot back, keeping a ſtraight, and yet a flexible arm, and at the very moment he lifts up his right foot to cloſe in, if even he ſhould force your blade, you muſt take the opportunity, and turning your wriſt ſwiftly in tierce, thruſt in this manner to his blade, forcibly and well maintaining your wriſt; this is called cavé; the thruſt finiſhed, you muſt recover to the ſword in a ſtraight line.

Of the Definition of the Wriſt, in Carte over the Arm, after the Thruſt in Tierce.

If you are engaged within the ſword, you muſt make an attack of the foot, and a beat on the blade. If the adverſary comes to the blade, diſengage nimbly to an outſide, with your wriſt turned in tierce, and deliver your thruſt in tierce; the thruſt made, immediately recover to your guard about a foot, and the moment he lifts up his foot to advance, you muſt ſeize that moment, and turning your wriſt on his blade, nails upward, thruſt carte over the arm; the thruſt made, you muſt recover to the ſword in tierce, or in half circle.

Of the Paſs on the Sword, in Carte over the Arm. Figure 22. Plate II.

If you find the adverſary engaged in tierce, with a bent elbow and a high point, you muſt recal him by an attack of the foot, and make a half thruſt to his ſword; if, after this he ſhould not anſwer your motion by coming to your ſword, then without altering the poſition of your right foot, bring up your left foot, and paſs it before the right, about two feet forward, the point of the foot a little outward, and raiſe the heel of your right foot a little, ſtretch out both knees, and let the weight of the body be on the left leg; and obſerve, that when you paſs your left leg forward, you turn your wriſt in carte over the arm, and with a ſtraight arm thruſt firm to the body; the moment you have made your thruſt, you muſt recover your guard in tierce, carrying, at the ſame time, your left leg, your body and arm to the firſt poſition, and ſeek his ſword with a circle parade.

Of the Paſs in Tierce on the Outſide of the Sword.

If the adverſary is engaged in carte, you make a ſtrong beat with your fort on his blade, and if, after you have put by his blade, he comes to a forced parry, diſengage ſubtilly to his outſide, with your wriſt raiſed in tierce, and the point plunged to his body; and at the very time of your diſengaging, bring up your left foot before the right about two feet, keeping the knees ſtraight, and the body reſting on the left leg; the thruſt made, recover to the ſword in tierce, throwing your body well back in a ſtraight line with that of the adverſary, and ſupporting it on your left ſide.

Of the Paſs in Carte, after the Feint in Carte over the Arm.

If you are engaged in carte, you muſt make an attack with the foot, and diſengage nicely; holding your wriſt in carte over the arm, make a half thruſt, by advancing your right foot about ſix inches, your wriſt well raiſed, and the point of your ſword firm in a line with your adverſary's face; and at the time he comes to join your blade to parry, you muſt ſurprize him by diſengaging artfully in carte, and make the paſs of the left leg forward, oppoſing your ſword to his, and keeping your wriſt high, and your point in a line to his; this done, recover, and ſeek his blade with a circle parade.

Of the Paſs in Carte over the Arm, after the Feint in Carte.

If the adverſary is engaged on the outſide of the ſword, you muſt make a half thruſt on the blade with an appel of the foot, and at the time that you feel him join and force your blade, feint on the inſide of the ſword, ſubtilly diſengage on the outſide, making your paſs with the left leg, and thruſt carte over the arm, according to the rules of this paſs before mentioned. You ſhould obſerve, that all the paſſes made on the outſide of the ſword, are parried with a high wriſt in tierce; and thoſe on the inſide are parried by the prime, or a high wriſt in carte, the wriſt being always in a line with the face.

An Evaſion, or Subterfuge, by the Removal of the left Leg backward, at the Time the Adverſary makes his Paſs on the Outſide of the Sword. Figure 23. Plate II.

You muſt give opening ſufficient on the outſide to encourage your adverſary to make a paſs, either in tierce or carte over the arm; and you muſt not ſtir or move by any attacks of the foot, or half thruſts, which he may make, but ſtill leave an opening to the outſide, to determine him to execute his thruſt, and at the time he makes his paſs with the left foot, drop your point in ſeconde, with the wriſt in tierce, without ſeeking his blade, and carry back your left foot, to its full extent of a ſtraight knee; nor ſtir the right foot, but keep the right knee bent as on a thruſt, having your body a little lower than in the ſeconde thruſt, your right arm very ſtraight, the wriſt up, and oppoſed to the face, the left arm falling perpendicularly between the two thighs, the palm of the hand open, facing the ground, for fear of a ſlip of the left foot backward, (which would make you loſe your centrical poſition,) and to enable you to keep up the body, by the aſſiſtance of the hand, in ſuch a caſe. This operation being performed, you muſt recover to a garde, and ſeek the blade by a circle.

Of the Seizing of the Sword after the Paſs on the Outſide of the Sword.

After having made the paſs, either in tierce or carte over the arm, if the adverſary parries the thruſt, and reſiſts to the blade, you muſt with agility and ſubtleneſs, ſeize the guard of his ſword with your left hand, that inſtant paſſing your right foot before your left, with your heels in a line, bending the knee a little, and ſtraightening the left knee; by this poſition you will be able to oppoſe his defence; if he ſhould take hold of your blade with his left hand, you ſhould immediately draw in your right, and preſent your point to his belly, holding faſt the ſhell of his ſword, to oblige him to give it up.

Of the Counter Diſengage on the Inſide of the Sword, ſtanding Still.

If you are engaged within the ſword, you ſhould bear a little on the adverſary's blade, to induce him to diſengage, and at the time of his diſengaging, either in tierce or in carte, to join your blade, you muſt ſeize that moment to time his motion by a counter diſengage, before he touches your blade, and thruſt a well oppoſed thruſt in carte; the thruſt made, recover immediately to the ſword in carte.

Of the Counter Diſengage on the Outſide of the Sword ſtanding Still.

You muſt engage the adverſary on the outſide, with the wriſt turned carte over the arm, the wriſt and point being in a line with the ſhoulder, the arm flexible, and you muſt bear on his blade to determine him to diſengage; and at the time he diſengages to join your blade on the outſide, diſengage ſubtilly with him before he joins your blade, and thruſt a full carte over the arm, oppoſing your wriſt and ſword according to the rules explained; the thruſt being made, recover quickly to the ſword, and redouble a thruſt in ſeconde.

Of the Counter to the Counter Diſengage, ſtanding Still.

If the adverſary ſhould offer to parry with a counter diſengage the thruſts above-mentioned, you ſhould, without ſeeking his blade, double your diſengage with ſpirit, and ſhunning his blade, thruſt with a ſtraight point at his body, and recover to the ſword by the circle parade.

Of the Counter Diſengage on the Time, and of the Counter to the Counter, when the Adverſary advances.

You muſt get out of diſtance about a foot, without leaving the adverſary's ſword; and at the time he advances, ſeize the opportunity, without ſeeking his blade, diſengage, and thruſt ſtraight at him; if he ſhould parry with a counter diſengage, you ſhould redouble the diſengage without ſeeking his blade, and thruſt out fully at him, having your body firm, and an oppoſite wriſt, according to the rules mentioned before: the thruſt being made, recover to a guard by a circle.

Of a Strait Time Thruſt, upon any low Feint.

If you are in diſtance with your wriſt turned in carte to the height of the ſhoulder, the point a little lower than the wriſt, and firm on your legs, you ought not by any means to be flurried, or ſtir, by any motion of the adverſary, either by appels or half thruſts; but be watchful to take advantage of any opening he may give at the time he lowers his wriſt and point, and makes low feints; at that inſtant, without ſeeking his blade, thruſt ſtraight forward in carte, with a well oppoſed wriſt, according to the rules; the thruſt made, recover, and ſeek the blade by a circle. You execute this ſame time thruſt alſo after having retired about a foot, by obſerving, the moment the adverſary lifts up the foot to come in diſtance, to leave his blade, and, if in the leaſt his wriſt ſhould be low, and you ſee opening enough, thruſt ſtraight at him, without ſeeking his blade, or heſitating in the leaſt. If he ſhould uncover the lower parts of the body at the time he comes in diſtance, you muſt time him, and thruſt a low carte with a well oppoſed and maintained wriſt, and recover to the ſword in tierce. If you are engaged on the outſide of the ſword, with the wriſt in tierce, you ſhould retire about a foot, and at the time the adverſary advances, giving the leaſt opening, you may thruſt carte over the arm; if he ſhould bear, and force your blade in the advance, you ſhould diſengage, and ſtop him by a carte within the blade. Nothing is more difficult than to thruſt with exactneſs and preciſion; the above-mentioned time thruſt cannot be performed well but by thoſe who have acquired, by practice and experience, theſe quick requiſites of the eye and wriſt to execute with. To ſhun the conſequences which might ariſe from theſe time thruſts; you ſhould be very attentive to hold your ſword well before you, nor give any openings by the feints you make, nor bear too much on the enemy's ſword in the attacks, either ſtanding ſtill or marching; and be always ready with a counter diſengage, cloſe and quick, or a circle; and never form an idea of giving a thruſt, without that of recovering quickly to a guard.

The Half Round, or Bounding Turn of the Body, called Demi-Volte. Figure 24. Plate II.

When you are in diſtance, you muſt engage the ſword in tierce, having the arm flexible, your body well on the left hip, and give your adverſary opening ſufficient on your outſide to engage him to thruſt; and at the time he forces your blade, either in tierce or carte over the arm, you muſt ſubtilly diſengage your point under the mounting of his ſword, with your wriſt as in carte, well oppoſed, and direct your point to his right breaſt; at the ſame time carry your left foot near the right, that the point of your left foot be about two inches behind the right heel, the two feet forming an angle; to complete this poſition, you ought to keep your knees ſtraight, your head erect and in a line with the right ſhoulder, and the left ſhoulder well turned out, with a ſtretched out arm, as in the carte thruſt. It is impoſſible to complete this volte, or turn of the body, with that vivacity and exactneſs it requires, without turning the point of the right foot inward, and lifting it up from the ground a little, and turning upon the heel your leg and thigh, as on a pully, that the body may be more thrown back in a ſtraight line with that of the antagoniſt, in order to ſhun the enemy's point; this done, you muſt recover with your left foot back, and come to a guard, according to the rules explained, with the circle parade. This ſame demi-volte may be made at the time the adverſary advances and forces your blade: the complete executing of this thruſt conſiſts in taking the juſt time.

Of the Flanconade Thruſt, having parried this Bounding Turn, called Demi-volte.

You muſt force the adverſaries blade on the outſide, to engage him to thruſt within; and if he ſhould make this demi-volte, you ſhould parry the thruſt, with the fort on his feeble, and binding the ſword, return a flanconade, with the oppoſition of the left hand, as before explained; this done, recover your ſword in carte.

The whole Round or Turn called the Volte, at the Time the Adverſary diſengages to Thruſt in Carte.

At the time the adverſary diſengages within, and thruſts carte, you muſt raiſe the wriſt to the height of your face, with your nails upward, and with ſwiftneſs and agility perform this turn of the body called volte; fixing your point to his right breaſt, ſtraighten your legs at the time you paſs with the left foot behind the right, which diſtance ſhould be about a foot; your left ſhoulder ſhould be turned outward, to form a complete ſide front or profile, to your adverſary, your head in a line with your ſhoulder and arm, to enable you to direct your point forward in that line. The thruſt being made, recover your guard with your wriſt in tierce, and beat ſmartly, with the fort of your tierce edge, on the feeble of his ſword, raiſing your wriſt and lowering your point.

Of the whole Turn called Volte, on the Paſs made in Tierce, or in Carte over the Arm. Figure 25. Plate III.

At the time the adverſary makes the paſs on the outſide of the ſword, you muſt paſs your point under his arm, and turn your wriſt in carte to the height of the face, paſs the left foot behind the right, about a foot diſtance, and fix your point to his right breaſt, ſtraightening both legs; at the very time you paſs the left foot, be careful that your left ſhoulder be well turned out, ſo as to be with your back half turned to the adverſary, holding your head in a line to the right ſhoulder and arm, in order to carry the point directly forward: this thruſt being executed, recover your guard by a circle, and keep your body very ſtaunch on the left ſide.

A Diſarm, after having parried the Carte Thruſt. Figure 26. Plate III.

If the adverſary is irregular and careleſs when he thruſts a carte, you ſhould parry him with the carte parade, by a dry, ſmart beat with your fort, at the ſame time advancing your right foot about a foot, and ſtraightening your left leg, you muſt ſeize the ſhell of his ſword with your left hand, and holding it faſt, preſent your point to his body under his arm; if he ſhould make any reſiſtance, and not ſurrender his ſword, you ſhould immediately bring up your left leg to the right, and with the fort of your ſword bear ſtrong on his blade, which will oblige him to open his fingers, and drawing in your arm, ſtill holding his ſword faſt, you will become maſter thereof; the diſarm being made, carry your left foot two feet back, with a ſtraight knee, and preſent the two points at him, as in Figure 27, Plate III.

Of the Diſarm on the Thruſt in Tierce, or Carte over the Arm. Figure 28. Plate III.

If the adverſary makes a thruſt in tierce, or carte over the arm, and abandons his body in a careleſs manner, you muſt parry him by a dry ſmart beat with the edge of your fort traverſing the line of the blade, and force or bear his wriſt upwards, at the ſame time paſſing the left foot about a foot before the right: if he ſhould reſiſt, or bring up his left foot to cloſe in and ſeize your blade; in ſuch a caſe, ſtill holding faſt his ſword, you ſhould throw his arm outward to the right, and carry your left foot forward about two feet, bending your right knee a little, and ſtraightening the left, preſent the point of your ſword to his face, raiſing your wriſt and arm to the height of your face, as you may obſerve in Figure 29, Plate III.

Of the Diſarm on the Carte or Seconde Thruſt, after having parried with the Prime Parade. Figure 30. Plate III.

If you are engaged in tierce, make an attack of the foot, and force the enemy's blade on the outſide, to excite him to thruſt; and at the time he thruſts either carte or ſeconde, parry quickly with the prime; and inſtead of traverſing the line to the right, as we have before mentioned in the articles of the parades, you muſt advance about half a foot, and with ſwiftneſs paſs your right arm over the fort of his blade; by this means, by drawing in your body and your left arm, he will be forced to quit his ſword: as ſoon as the diſarm is made, preſent your point, and paſs ſwiftly back, with your right foot at two feet diſtant from the left, as you will ſee in Figure 31, Plate III.

Of the Diſarm after the Parade on the Outſide of the Sword.

If you are engaged on the outſide, either in tierce or carte over the arm, you muſt make an appel of the foot, and force or bear a little on his blade, to excite him to thruſt a carte within the ſword. At the time he diſengages and thruſts out, you muſt counter-diſengage and parry, forcing his blade upward with the fort of yours: you are to paſs your left foot before the right, about the diſtance of a foot, and with livelineſs and reſolution, with your left hand, ſeize the ſhell of his ſword; and as in defending himſelf he might bring up his left leg, and throw himſelf forward on the blade; to hinder his ſeizing it, you ſhould inſtantly throw your right ſhoulder and arm back, and carry your right foot behind the

the left about a foot, and turning the point of your left foot facing his knee, and paſſing your ſword behind your back, leaning your wriſt againſt your loins, preſent the point of your ſword to his belly. You muſt always obſerve that, in all diſarms, you are never to ſeize the adverſary's arm, nor his blade, with your left hand; for in ſeizing his arm he may again recover his ſword, by ſhifting or throwing it from the right to the left, and having caught hold of it by the gripe, or by the fort of his blade, he may with a drawn in arm ſtab you; and was you to ſeize his blade, he might alſo draw in his arm, and draw it through your hand in a fatal manner. In my opinion, all thoſe diſarms which we have explained, are more brilliant and fine in a fencing ſchool, with a foil in hand, when very well executed, with the utmoſt preciſion and judgement than they are uſeful ſword in hand; nevertheleſs, they may be made uſe of againſt thoſe who abandon their bodies after they thruſt, and who do not recover with that quickneſs and care which is neceſſary. Sword in hand, we prefer the bindings and croſſings of the blade, or the ſmart dry beat with the fort on the feeble of the adverſary; by all theſe you run no riſque; for if you do not beat the ſword out of the hand, you will always get opening thereby to throw in a thruſt if you deſign it.

The Italian Guards with the Sword and Dagger.

This exerciſe of ſword and dagger is only made uſe of in Italy. When the ſcholar has learnt to handle his ſword well, he is afterwards inſtructed how to uſe the ſword and dagger: the Italians ſeldom go out at night without theſe two weapons. The right handed man carries his dagger by the ſide of his right thigh, and the left handed man by his left: they draw this weapon the moment they have ſword in hand. Naples is the city where theſe are moſt commonly uſed, and with moſt dexterity. Though there is no uſe made of the ſword and dagger in this country, we thought it neceſſary to give an explanation thereof, that gentlemen may know how to defend themſelves if they ſhould travel in countries where they are uſed, and not be embarraſſed when they ſee two points at once before them. We ſhall therefore give two different guards, which are the moſt made uſe of in this exerciſe; and will afterwards explain the manner in which a ſingle ſword is to defend itſelf againſt the ſword and dagger. You muſt place yourſelf in guard, with the dagger and arm ſtretched out, and at ſome diſtance from the hilt of your ſword, to execute and form the parades as cloſe as poſſible; which is very difficult with a ſtraight arm. You muſt obſerve that, in covering one ſide, you do not uncover another. In this guard there is no ſingling the body, for the left ſhoulder projects more than the right; and though the right arm covers the outſide of the ſword, it ought to be contracted. When in this poſition you can form your parades well, you will put yourſelf in guard, your ſword arm ſtraight but not ſtiff, and your left drawn in, having the point of your dagger near the right elbow. The principal point is not to flutter, or ſtir at any motion made by the adverſary; if he ſeeks his ſword with his, you muſt ſlip him, unleſs you find yourſelf firm enough to oppoſe him therewith, cloſing in about ſix inches, and without quitting his ſword, ſtrive to get his feeble on the fort of your dagger, and quitting his ſword, it will be eaſy to deceive his dagger, and hit him. In this operation, you muſt not quit his blade with your dagger, and the longer his ſword is, the greater will be your advantage, and alſo on any parade made with the dagger, you ought not to quit the blade, if you have a mind to return the thruſt. The Italians frequently parry with the dagger, therefore it is evident, that he who can parry with two blades has a great advantage, provided it be done without hurry, and with judgment, for otherwiſe he would only leave himſelf continually open. You ſhould baulk your adverſary at the time he makes an attack, or half thruſts, by not ſtirring your ſword, but make ſome wide motions with the dagger, to engage him to thruſt, and as ſoon as he delivers his thruſt, parry with your dagger; cloſe at the ſame time in with him, make a feint with your ſword toward his face, and thruſt at the body, as you ſee in

Figure 33. Plate III.

The Italians defend all the inſide, and the lower part of the body with the dagger, and as they depend entirely on this parade, they lower the outſide with the point of their ſwords.

The ſingle Sword, againſt the Sword and Dagger.

As all the thruſts which the ſingle ſword makes on the inſide, againſt the ſword and dagger, may eaſily be parried; the return of the adverſary's point would infallibly hit, therefore you ſhould act with great judgment and attention. You muſt come to a garde, with your wriſt turned between tierce and carte, and a little lower than the ordinary garde, fixing the point to the adverſary's right ſhoulder, you muſt not engage his ſword, but make frequent beats on his outſide, and attacks with the foot, always directing your point to his face, to oblige him to raiſe his wriſt, which time you muſt ſeize with preciſion, and with ſwiftneſs and vivacity, deliver your thruſt in ſeconde, and return as quick to the prime parry or circle. If he ſhould be in guard with the point in a line with his ſhoulder, you ſhould feint on his inſide, and return with a beat on the outſide, from your fort on his feeble, and deliver a thruſt carte over the arm. If he ſhould hold his point lower than his wriſt, you ſhould place yourſelf ſo likewiſe on his inſide, and making a half thruſt on the inſide, immediately bind is blade ſmartly, and thruſt a flanconade. You may alſo after the half thruſt, croſs bind his ſword, and make your thruſt in tierce; we would not adviſe any body to thruſt on the inſide, becauſe the dagger will be very apt to parry, and thereby you would be liable to the return of the ſword, but when the adverſary is not ſtaunch in his parades, and flutters, ſeeking to parry with his ſword the attack you make on him; in ſuch a caſe, after having made a half thruſt on the inſide, and on the outſide of the dagger, deliver a low thruſt in carte; recover to a guard in tierce, oran half circle.

Of the Spaniſh Guard defeated, after the Attempt of the Cut on the Head. Figure 34. Plate III.

If you make uſe of a ſword of common length, and if you can but ſtand the firſt attack, you will eaſily defend yourſelf againſt a Spaniard, and will be very little embarraſſed by his play or method. You ought to put yourſelf in guard out of diſtance, with your wriſt turned in tierce, holding it a little higher than in the ordinary guard, with great coolneſs, nor anſwer any motion he may make or attempt. If he ſhould attempt the cut on the head, you ſhould parry it with a high tierce, ſtill raiſing your wriſt and bending your body, and cloſe in about a foot or more; after which briſkly return a full ſtretched out thruſt in ſeconde, with your point lower than common in that thruſt, that he may not be able to parry it with his left hand. The thruſt being made, recover inſtantly to a tierce, and traverſing the line to the right, with a forcibly oppoſed wriſt, ſeek his ſword again; at the ſame time bring up your right foot to your left, to throw off his point: ſo will you be enabled to get ground to advantage with the left foot. If the adverſary makes a thruſt to the face or body, you muſt parry it by diſengaging from tierce to carte, keeping your wriſt in a line with the ſhoulder, and at the ſame time cloſe in a full foot, to get within his blade as much as poſſible, and to be able to return a thruſt in carte. If he wants to parry with his left hand, you muſt feint on it, making at the ſame time an appel of the foot, to baulk his left handed parade, and finiſh his thruſt according to the forementioned rules; recover quickly your ſword, with your point to his face, and redouble a low carte. This done, recover to a guard, carrying your right foot behind your left. Though it ſeems eaſy for the ſhort ſword to diſarm the long ſword after you have the advantage of getting within his blade, we would nevertheleſs adviſe not to attempt it, for fear you ſhould not be able to reach the ſhell of his ſword, or for fear of having your fingers cut by the edges of it. We alſo would not adviſe any body to croſs or bind, or to beat on their blades, becauſe the Spaniards, when they draw their ſwords, paſs the two firſt fingers through two ſmall rings which are near the ſhell, and with the two others and the thumb they have a faſt hold of their gripe: therefore it is evident that none of theſe laſt mentioned operations would be ſucceſsful.

Explanation of the Guard called Sword and Dark Lanthorn.

Figure 35. Plate III.

Though there are ſevere puniſhments inflicted on thoſe who are found ſword in hand with a dark lanthorn, yet there are ſome to be met with form time to time; therefore we think it neceſſary to ſhew the manner of defence againſt it. Thoſe who uſe the dark lanthorn commonly hide it under their clothes or cloak; and when they attack any body they open it before they draw their ſword, and preſent it before them either above their head, or behind them, by turning the hand behind their back; and change the poſition thereof as the adverſary changes his poſition. If they hold their lanthorn before them, and one is provided with a good ſword, one ought to cover the inſide well with the cloak, and give a ſmart beat on the inſide of their blade, and redouble it with a back handed blow in tierce on the wriſt which holds the lanthorn: this blow ought to come from the right to the left, and it ought to be executed from the half arm only to the wriſt, that the whole arm go not aſtray too much by it, and that one may be able to return a thruſt with the wriſt in the ſame ſituation, covering the inſide of the body with the cloak. If he ſhould preſent the lanthorn over his head, you ſhould traverſe to the right, and get the advantage of the outſide of his ſword, making half thruſts to the face. If he raiſes his point you ſhould cloſe in diſtance, holding both hands high, and keeping the blade over the left wriſt and cloak, and make a paſs with the left foot without leaving his ſword, and aſſiſting with the cloak, draw in the right arm a little, to diſentangle your point, and in the poſition your wriſt finds itſelf ſituated at that time, thruſt with ſpirit and agility directly at the adverſary. If he preſents the lanthorn by the ſide, with his arm turned behind him, you muſt traverſe the line to the inſide, holding your hand and cloak in the line with your right breaſt, turning your right hand in tierce, the point of your ſword directly to his belly; and the moment he delivers his thruſt, inſtead of parrying it with your ſword, ſtretch out your left arm and cover his blade with your cloak, at the ſame time thruſting at the body, as you ſee in this Figure. If the adverſary ſhould be garniſhed (that is, ſtuffed with ſomething within his clothes, to prevent a thruſt going through to the body) which you will find out by the thruſt being planted at his body without effect; in ſuch a caſe, you muſt thruſt at the throat or at the face, or at the lower part of the waiſt; for it is ſuppoſed that the man who will make uſe of ſo unlawful means as a dark lanthorn in any particular combats, will not ſcruple to uſe the means of garniſh, as before mentioned.

FENCING.

Explanation of the Defenſive Guard of the Small Sword againſt the Broad Sword. Figure 36. Plate III.

The guard of the ſmall ſword marked B, againſt the broad ſword marked A, which we have placed here, is the moſt ſafe, and the moſt ſheltered guard for defence. The chief point will be, to know your diſtance: in whatever poſition the broad ſword man may put himſelf, you muſt place yourſelf out of diſtance, and bring neither your wriſt nor your ſword, nor your right foot forward: but the moment you draw your ſword, you muſt, with your left hand, take up the ſkirts of your coat, keeping your left hand to the height of your ear, in order occaſionally to parry the cuts of the broad ſword on the inſide, either at the head, face, or the lower part of the body. The blow at the head may likewiſe be parried with the fort of your blade, having the wriſt in tierce, and oppoſing the blade almoſt croſſing the line; but your point ſhould be a little higher than the mounting of your ſword: the moment the blow is parried, you muſt cloſe in about a foot, and bending the body a little, return a thruſt in ſeconde, and redouble the thruſt before you recover your guard. Parry the cut on the outſide of the blade to the face with the fort of your blade, and your wriſt turned half way to tierce with a ſtraight point. The blow being parried, you muſt return a thruſt to the face in carte over the arm, and redouble the ſame with a ſeconde. The cut at the belly on the outſide of the ſword, is to be parried by turning your wriſt to a ſeconde, and returning on the ſame ſide. If you parry the inſide cuts which may be made at you with your blade, you ſhould parry them with the prime parade, at the ſame time traverſing the line to the outſide, and return a thruſt in prime. The ſafeſt and ſureſt defence againſt the broad ſword (in our opinion) is not to be fluttered or moved at any motion, ſham blows, or attacks; and if his motions are wide, you muſt reſolve to cloſe in, covering yourſelf as much as poſſible with your ſword and the lap of your coat, and deliver your thruſt where you ſee an opening to hit him. If the ground ſhould not be level enough to tire him, you ſhould, by turning to the right or to the left, and by retreating, take a favourable and exact juſt time for thruſting, inſtead of throwing the thruſt at random. There are ſome broad ſword men who intermix their play with thruſts (which is called counter point) they feign to give a cut, and finiſh it with a thruſt; and ſometimes, after having parried, according to the opening they find, they will return either a cut or a thruſt. The ſword called cut and thruſt is very different from the broad ſword, becauſe it is much lighter, it carries a ſtraight point, and not a raiſed one, as the ſabres or cutting ſwords commonly have; for which reaſon they are obliged to make the hilts heavy, to render the point light. The half cut and thruſt ſword is preferable to the broad ſword, provided it be made uſe of with judgment. This weapon is the beſt for horſemen, when they charge their enemy ſword in hand.

Obſervations on Left Handed Fencers.

It often happens that the right handed fencer is much embarraſſed in defending himſelf againſt a left handed one, occaſioned by the conſtant habit of fencing always with right handed fencers, which gives the left handed fencer a conſiderable advantage. You ſeldom have occaſion to fence with a left handed man, becauſe the number of theſe is but ſmall; and for the ſame reaſon, when two left hands meet, they are equally at a loſs with one another. To obviate this inconveniency, we are of opinion, that a fencing maſter ſhould accuſtom his ſcholars to fence with both hands; that is to ſay, that when the pupil has learnt to handle his foil well with the right hand, he ſhould be exerciſed with the left hand. This practice will be found hard to every body, but with a good will, and by taking pains, you may attain to a degree of perfection which will be advantageous to yourſelf, and will do honour to him that teaches. The maſter ſhould not only uſe his ſcholars to take leſſons with both hands, but ſhould likewiſe uſe them to fence looſe, calling aſſaulting; this method would enable them to defend themſelves with both hands, and they would never be at a loſs againſt an adverſary who might preſent himſelf to them in a different poſition than their own. When a right handed and a left handed fencer are together, they ought to be attentive, both of them, to keep the outſide of the ſword; this ſide being the weakeſt, they have both of them the facility of beating, or making a glizade or preſs on the outſide of the blade. If the beat is given properly, it is almoſt impoſſible that the ſword doth not drop out of the hand, except the adverſary takes the preciſe time of the beat, either by diſengaging, or by turning his wriſt in tierce. You muſt obſerve alſo, that the right handed fencer ought to thruſt carte inſtead of tierce, to the left handed one, and tierce inſtead of carte; that is to ſay, that he ought to thruſt all the outward thruſts within, and the inner thruſts outward. The ſame rules alſo are for the left hand to the right handed fencer; by this means the hand will always be oppoſed to the ſword, and the body and face will always be covered.

The following is an extract from Mr. Olivier's Treatiſe on Fencing, with additions, never before in print, which the publiſher was favoured with by that gentleman.

Of Judgment.

Nothing is ſo neceſſary in fencing as judgment; it enables us to face all ſorts of methods with advantage, to foreſee the thruſts of an adverſary, and to judge of his parades in order to elude them; it is by judgment alone that we are capable of arranging our parades and directing our thruſts; therefore maſters cannot too ſoon implant it in the minds of their ſcholars; for they ſhould never teach them a parade, without telling them by what feint they may deceive it, and explaining to them the various changes to which each thruſt is ſubject. To make it more clear, the maſter ſhould in his leſſon reaſon with his ſcholar in the following manner:

Dialogue between the Maſter and the Scholar.

M. When you perceive that I am about to parry your thruſt over the arm with the ſimple parade of tierce, what are you to do to avoid my parade? — *S.* I make the feint une-deux in carte within the arm? — *M.* If I had made uſe of the counter in carte? — *S.* I Should have avoided your counter in carte by changing twice round over the arms, what we call doubling? — *M.* What parade muſt I take to prevent your doubling? — *S.* Having parried with the counter in carte, miſſing the blade, you ſtop my doubling with the parade of tierce or ſemi-circle? — *M.* When I parry feint une-deux, over the arms with the counter in carte, what are you to do to avoid my parade? — *S.* I make the feint une-deux, and ſeize the time of your round parade to puſh double carte over the arms? — *M.* When I parry the feint une-deux in carte with the parade of ſemi-circle, what are you to do to deceive that parade? — *S.* I make the feint une-deux, and as ſoon as you form the parade of ſemi-circle, I go round your blade and puſh low carte? — *M.* If I had parried with the circle? — *S.* I ſhould have been twice round, and puſhed double carte within the arms? *M.* When you fence with an adverſary who keeps a ſtraight guard what are you to do? — *S.* I am to make ſeveral beats with the right foot upon the ground, if that does not put him in diſorder, I am to give him a dry beat upon the foible of his ſword in order to throw it away, then I am to puſh a ſtraight thruſt?

M. What is the moſt proper time to attack one's adverſary? — *S.* When the leaſt motion puts him in diſorder, or when he breaks ground? — *M.* Do not you fear his retreat is but a ſnare to take the time? — *S.* In cloſing on him I make ſure of his ſword, and know by the feel of it whether he has a mind to thruſt or parry? — *M.* When you have to deal with an adverſary that does not feel your blade, and puts himſelf in an open guard with the point of his ſword downwards, what will you do? — *S.* I am to make falſe attacks to oblige him to take a proper guard and only thruſt when he anſwers them? — *M.* Which are the beſt parades in fencing? — *S.* The counter parades and the circles, becauſe they baffle all the feints? — *M.* How can you tell when your adverſary will make uſe of them? — *S.* In diſengaging ſlightly on one ſide to the other, or by the feel of his ſword? — *M.* What are the beſt thruſts in fencing? — *S.* The ſtraight thruſt puſhed with ſwiftneſs; they are the only ones we ought to thruſt when in reach, becauſe they expoſe the leaſt? — *M.* Which is the way to acquire ſwiftneſs? — *S.* It is to puſh frequently tierce and carte; for by that exerciſe only you gain ſwiftneſs, firmneſs, and exactneſs, &c. *M.* How many guards are there in ſmall ſword play? — *S.* Two, called tierce and carte. — *M.* How many engagements are there in fencing? — *S.* Two, called alſo carte and tierce (engagement is a ſynonimous term with guard.) — *M*, How many parades are there, and how are they divided? — *S.* Six ſimple parades and ſix compound, they are divided in carte, tierce, ſemicircle, octave, prime, ſeconde, or quinte; carte ſemicircle and prime, are the inward parades, and tierce octave and ſeconde or quinte are the outward parades. — *M.* Which is the beſt method to form the defence? — *S.* The counter parades in carte, tierce, the circle, octave, carte, and the counter parades in carte again: what we call the ſucceſſion of parades, to form a regular defence, in order to baffle all feints. — *M.* Can you confine your defence in fewer parades? — *S.* The counter parade of carte, the circle, and from the circle to the double counter in carte, obſerving to make the counter parades and circles ſmall from the wriſt, but wide from the point, in order to cover all the body from any wide or low thruſt, taking particular care to bring the point of the ſword in a line with the adverſary's body after the parades. — *M.* What is the beſt method to begin an attack? — *S.* By making an extenſion of the arm, either in carte or tierce, to oblige the adverſary to open his guard, and in the moment that he does ſo, ſeize the advantage it will give, by throwing a thruſt accordingly.

This Treatiſe is principally formed from the works of Meſſrs. Angelo and Olivier. The deſcriptions which illuſtrate the plates, are taken from Mr. Angelo; as he has been more copious, and introduced a greater variety of poſitions and engagements than any other writer on the ſubject. For many of the other parts I am indebted to Mr. Olivier, who has greatly ſimplified the manner, and rendered it more eaſy to the young practitioner in the art. I cannot but obſerve, in juſtice to the latter, that his method of teaching is far ſuperior to that adopted in any of the ſchools wherein I have practiſed: nor can I permit this opportunity to paſs without expreſſing my acknowledgment to that gentleman, for the conſiderable aſſiſtance he has afforded me in compoſing this Treatiſe. Thoſe who wiſh to attain a proficiency in the practical part of the art, I cannot recommend to a better maſter than Mr. Olivier, whoſe terms of teaching may be known by referring to the wrapper, No. 73, of this work.

C. COOKE.

PATER-NOSTER ROW.

FENDUE *en pal*, in heraldry, a French phraſe, applied to a croſs, to denote it cloven down from top to bottom and the parts ſet at ſome diſtance from one another.

FENNEL, in botany. See ANETHUM.

FEODAL, *Feodalis*, or *Feudalis*, of or belonging to a feud, or fee. Hence feudal ſervices, &c. See FEE.

FELÆ, in the Linnæan ſyſtem, one of the orders of animals, of the claſs of mammalia; the characters of which are, that they have ſharp teeth; the upper four-teeth are ſix in number, and the canine or dog teeth longer than the reſt. Of this order are the bear, the lion, the tyger, the cat, the weaſel, the ferret, the didelphis or philander, the otter, the ſea-calf, the dog, the badger, the hedge-hog, the mole, and the bat, which this author makes not a bird, but a quadruped, with its fore-feet expanded into a ſort of wings, &c. For the claſſification ſee MAMMALIA or Syſtem of QUADRUPEDS.

FERIÆ, among the Romans, were holy-days, or days wherein they abſtained from work. The *feriæ*, or *dies ferati*, were obſerved and diſtinguiſhed chiefly by reſt; whereas the *feaſts*, or *dies feſti*, beſide a ceſſation from labour, were celebrated with ſacrifices and games; ſo that there were *feriæ*, which were not feaſt days; though authors frequently confound the *feriæ* and *feſti*.

FERMENT, any body which, being applied to another, produces fermentation. Ferments are either matters already in the act of fermentation, or that ſoon run into this act. Of the firſt kind are the flowers of wine, yeaſt fermenting beer, or fermenting wine, &c. and of the ſecond are the new expreſſed vegetable juices of ſummer-fruit. Among diſtillers, ferments are all thoſe bodies which, when added to the liquor, only correct ſome fault therein, and, by removing ſome obſtacle to fermentation, forward it by ſecondary means: as alſo ſuch as, being added in time of fermentation, make the liquor yield a larger proportion of ſpirit, and give it a finer flavour.

FERMENTATION may be defined a ſenſible internal motion of the conſtituent particles of a moiſt, fluid, mixed, or compound body: by the continuance of which motion, theſe particles are gradually removed from their former ſituation or combination, and again, after ſome viſible ſeparation is made, joined together in a different order and arrangement, ſo that a new compound is formed, having qualities very ſenſibly different from thoſe of the original fluid. Fermentation, properly ſo called, is confined to the vegetable and animal kingdoms; for the efferveſcences between acids and alkalies, however much they may reſemble the fermentation of vinous liquors, are nevertheleſs exceedingly different. It is divided into three kinds; or rather, there are three different ſtages of it, viz. the vinous, the acetous, and the putrefactive. Of the firſt, vegetables alone are ſuſceptible; the fleſh of young animals is in ſome ſlight degree ſuſceptible of the ſecond; but animal ſubſtances are particularly ſuſceptible of the third, which vegetables do not ſo eaſily fall into without previouſly undergoing the firſt and ſecond. The produce of the firſt ſtage is wine, or ſome other vinous liquor; of the ſecond, vinegar; and of the third, volatile alkali. See BREWING, VINEGAR, &c. Fermentation is one of the moſt obſcure proceſſes in nature, and no attempt has been made to ſolve it with any degree of probability. All that we know with regard to it is, that the liquor, however clear and tranparant at firſt, no ſooner begins to ferment, than it becomes turbid, depoſits a ſediment, emits a great quantity of fixed air, and throws up a ſcum to the top, acquiring at the ſame time ſome degree of heat. The heat of the vinous ſtage, however, is but moderate, ſeldom or never exceeding that of the human body. The heat of the acetous is conſiderably greater; and that of the putrefactive is the greateſt of all, inſomuch that putrefying ſubſtances, when heaped together in great quantities, will ſometimes break forth into actual flame. From theſe phenomena, fermentation ſhould ſeem to be a proceſs ultimately tending to the entire diſſolution of the fermenting ſubſtance, and depending upon the action of the internal heat, etherial fluid, or whatever elſe we pleaſe to call it, which pervades, and makes an eſſential ingredient in, the compoſition of all bodies. From ſuch experiments as have been made upon this ſubject, it appears, that whether fixed air is the bond of connection between the particles of terreſtrial bodies or not, yet the emiſſion of it from any ſubſtance is always attended with a diſſolution of that ſubſtance. We cannot, however, in the preſent caſe, ſay that the emiſſion of the fixed air is the cauſe of the fermentation. It is in fact otherwiſe. Fixed air hath no tendency to fly off from terreſtrial ſubſtances with which it is united; on the contrary, it will very readily leave the atmoſphere, after it hath been united with it, to join itſelf to ſuch terreſtrial ſubſtances as are capable of abſorbing it. The emiſſion of it, therefore, muſt depend upon the action of ſome other fluid; moſt probably the fire or heat, which is diſperſed through all ſubſtances in a latent ſtate, and in the preſent caſe begins ſenſibly to manifeſt itſelf. But from what cauſe the heat originally begins to operate in this manner, ſeems to be entirely unknown and inexplicable, except that it appears ſomehow or other to depend on the air; for, if that is totally excluded, fermentation will not go on.

FERN, FELIX, in botany. See FILICES. Fern is very common in dry and barren places. It is one of the worſt weeds for lands, and very hard to deſtroy where it has any thing of a deep ſoil to root in. In ſome grounds, the roots of it are found to the depth of ſix feet. One of the moſt effectual ways to deſtroy it is, often mowing the graſs; and, if the field is ploughed up, plentiful dunging thereof is very good. In ſome places of the north, the inhabitants mow it green; and, burning it to aſhes, make thoſe aſhes up into balls with a little water. They then dry them in the ſun, and make uſe of them to clean their linen with; looking upon it to be near as good as ſoap for that purpoſe. It is ſaid, that the frequent treading them down by ſheep, while that ſort of cattle feed upon them, is an infallible method of killing them. The ancients uſed the root of the fern and the whole plant, in decoctions and diet drinks, in chronic diſorders of all kinds ariſing from obſtructions of the viſcera, particularly in hypochondriac caſes, and in obſtructions of the ſpleen and pancreas. There are not wanting modern authors who give it as high a character in theſe caſes as the ancients have done; but it is an ill taſted medicine, and in no great uſe in the ſhops. The country people eſteem it as a ſovereign remedy for the worms; and they give it as a powder, after drying it in an oven. As aperients and anthelmintics, the roots have been in high eſtimation with ſome; and Simon Pauli tells us, that they have been the grand ſecret of ſome empirics againſt the broad worm, called tænia. In the Medical Commentaries, vol. vi. p. 307. are given ſome inſtances of the ſucceſs of this remedy, by Dr. Duncan of Edinburgh.

FERRET, an animal of the Muſtella or Weazel kind. See MUSTELLA.

FERRETTO, in the glaſs-trade, a ſubſtance which ſerves to colour glaſs. This is made by a ſimple calcination of copper, but it ſerves for ſeveral colours. There are two ways of making this; the firſt is as follows; take thin plates of copper, and lay them on a layer of powdered brimſtone, in the bottom of a crucible: over theſe lay more brimſtone and over that another layer of the plates, and ſo on alternately till the pot is full. Cover the pot, lute it well, place it in a wind-furnace, and make a ſtrong fire about it for two hours. When it is taken out and cooled, the copper will be found ſo calcined that it may be crumbed to pieces between the fingers like a friable earth; it will be of a reddiſh, and in ſome parts a blackiſh colour. This muſt be powdered and ſifted fine for uſe. Neri's Art of Glaſs, p. 30. The other way is leſs eaſy, but it makes a more valuable ferretto. It is this; make a number of ſtratifications of plates of copper and powdered vitriol alternately in a crucible, which place on the floor of the glaſs-furnace near the eye, and let it ſtand there three days; then take it out, and make a new ſtratification with more freſh vitriol, and calcine it again as before: repeat this operation ſix times, and a moſt valuable ferretto is produced.

FERRUGINOUS, denotes a thing to partake of the nature of iron, or to contain particles of that metal. It is particularly applied to certain mineral ſprings, whoſe water in their paſſage along the ſtrata of the earth meets with the ore of this metal, or with pyritæ containing it, part of which they waſh off, and carry with them; and thus become impregnated with the principles thereof. Such are what we call chalybeat waters. The waters of Tunbridge, thoſe of Forges, and of the iron ſpring at Bourges, and many others, are ferruginous.

FERRUGO, the ruſt of iron, or a kind of calx found on the ſurface thereof. The ruſt of iron is a reſtringent; applied by way of peſſary, it repreſſes the fluor uterinus; and drank, prevents conception; it cures the eryſipelas, and exanthematous eruptions. It is of good uſe in a paronychia, roughneſs of the eye-lids, and a condylema. It alſo ſtrengthens the gums, relieves under the gout, being rubbed on the part affected, and makes the hair grow after an alopecia. Wine or water, in which red hot iron has been quenched, being drank, is good for the cœliac paſſion, dyſentery, diſorders of the ſpleen, cholera morbus, and relaxations of the ſtomach.

FERRY, a liberty by preſcription to have a boat for paſſage upon a river, for the carriage of horſes and men for a reaſonable toll; it is uſually to croſs a large river.

FERTILITY, fruitfulneſs, that quality which denominates a thing fertile or prolific. Nothing can produce fertility in either ſex but what promotes perfect health; nothing but good blood, ſpirits, and perfect animal functions, that is, high health, can beget perfect fecundity; and therefore, according to Dr. Cheyne, all means and medicines, all noſtrums and ſpecifics to procure fertility, different from thoſe which procure good blood and ſpirits, are arrant quackery and cheating. He ſays, that water-drinking males are very rarely infertile; and that if any thing in nature can prevent infertility, and bring fine children, it is a milk and ſeed-diet, perſevered in by both parents. To increaſe the fertility of vegetables, ſays lord Bacon, we muſt not only increaſe the vigour of the earth and of the plant, but alſo preſerve what would otherwiſe be loſt: whence he infers, that there is much ſaved by ſetting, in compariſon of ſowing. It is reported, continues he, that if nitre be mixed with water to the thickneſs of honey, and after a vine is cut, the bud be anointed therewith, it will ſprout within eight days. If the experiment be true, the cauſe may be in the opening of the bud, and contiguous parts, by the ſpirit of the nitre; for nitre is the life of vegetables. How far this may be true, is not perhaps ſufficiently ſhewn, notwithſtanding the experiments of Sir Kenelm Digby and M. Homberg. Conſult Mr. Evelyn's Sylva, the Philoſophical Tranſactions, the French Memoirs, and Dr. Stahl's Philoſophical Principles of Chymiſtry: but a proper ſet of accurate experiments ſeems ſtill wanting in this view.

FERULÆ, among ſurgeons, called alſo ſplinters, are little chips of different matter; as of wood, bark, leather, paper, &c. applied to bones that have been disjointed when they are ſet again.

FESSE, in heraldry, one of the nine honourable ordinaries of the eſcutcheon, which it divides horizontally in the middle, and ſeparates the chief from the point. It is ſuppoſed to repreſent a broad girdle or belt of honour, ſuch as thoſe with which knights at arms weje anciently girded.

FESSE *Point*, is the exact centre of the eſcutcheon. It is thus called, as being the point through which the feſſe line is drawn from the two ſides: and accordingly it divides the eſcutcheon into two equal parts when the eſcutcheon is parted *per feſſe*.

FESTI *Dies*, among the ancients, were feaſt-days or holidays.

FESTOON, in architecture and ſculpture, is a decoration in form of a garland or cluſter of flowers. The word is French, *feſton*, which ſignifies a *garland*, formed of the Latin, *feſtum*, *feaſt*. It conſiſts of a ſtring or collar of flowers, fruits, and leaves, tied together, ſomewhat biggeſt in the middle, and ſuſpended by the two extremes; from which, beſide the main part which falls down in an arch, two leſſer parts hang perpendicularly. This ornament is made in imitation of the feſtoons or long cluſters of flowers, hung by the ancients on the doors of their temples, &c. on feſtival occaſions. Feſtoons are now chiefly uſed in freezes, tablets, and other vacant places, required to be filled up and adorned. They are ſometimes uſed over or under a niche.

FET-*Lock*, a tuft of hair growing behind the paſtern joint of horſes. Hence, the joint where it grows is called the fet-lock joint.

FEUD, FEODUM, the ſame with fief or fee. Eſtates in land were originally at will, and then they were called *munera*; afterward they were for life, and then they were called *beneficia*; and for that reaſon the livings of clergymen are ſo called at this day; and afterward they were made hereditary, when they were called *feoda*, and in our law fee-ſimple. When Hugh Capet uſurped the kingdom of France, about the year 947, to ſupport himſelf in ſuch uſurpation, he granted to the nobility and gentry, who till then generally enjoyed their honours for life, or at will only, that they ſhould from thence-forth hold them to them and their heirs. However, under the reign of Ludovicus Pius, who ſucceeded his father A. D. 814. grants of hereditary fiefs were frequent in France. Dr. Robertſon obſerves, that a character of King Robert of France, A. D. 1008, is the earlieſt deed in which he has met with the word *feudum*. Hiſt. Ch. V. vol. i. p. 269. This was imitated by William, called the Conqueror, upon his acceſſion to the crown of England; for till his reign feuds or fees were not hereditary, but only for life, or for ſome determinate time. See FEE.

FEUD is alſo uſed in our ancient cuſtoms for a capital quarrel or enmity, not to be ſatisfied but with the death of the enemy; and thence uſually called deadly feud.

FEUDAL, or FEODAL, of, or belonging to a feud or fee. We ſay, a feudal matter, feudal juriſprudence, feudal ſeiſure, &c. A feudal lord, in default of fealty and homage from his vaſſal, may ſeize the fruits of the fee. See FEE.

FEVER, FEBRIS, in medicine, a diſeaſe, or rather claſs of diſeaſes, whoſe characteriſtic is a preternatural heat felt through the whole body, or, at leaſt, the principal parts thereof, attended with other ſymptoms. See Syſtem of MEDICINE.

FIAT, in law, a ſhort order or warrant ſigned by a judge, for making out and allowing certain proceſſes.

FIBRARIÆ, a claſs of foſſils, naturally and eſſentially ſimple, not inflammable nor ſoluble in water; and compoſed of parallel fibres, ſome ſhorter, others longer; their appearance being bright, and in ſome degree tranſparant: add to this, that they never give fire wih ſteel, nor ferment with or are ſoluble in acid menſtrua.

FIBRE, in anatomy, a perfectly ſimple body, or at leaſt as ſimple as any thing in the human ſtructure; being fine and ſlender like a thread, and ſerving to form other parts. Hence ſome fibres are hard, as the boney ones; and others ſoft, as thoſe deſtined for the formation of all the other parts.

The fibres are divided alſo, according to their ſituation, into ſuch as are ſtraight, oblique, tranverſe, annular, and ſpiral; being found arranged in all theſe directions in different parts of the body. Fibre is alſo uſed to denote the ſlender filaments which compoſe toher bodies, whether animal, vegetable, or mineral; but more eſpecially, the capillary roots of plants.

FIBROSE, ſomething conſiſting of fibres, as the roots of plants.

FIBULA, in anatomy, one of the bones of the leg, called alſo *perone*, *ſura*, and *focile minus*. See Syſtem of ANATOMY, Part II. Sect. XII, Plate I. Oſteology, Fig. I, Letter *h*.

FICTION, See FABLE.

FICUS, the fig-tree; a genus of the trioecia order, belonging to the polygamia claſs of plants. There are ten ſpecies, of which the following are the moſt remarkable.

1. The carica, or common fig, with an upright ſtem branching 15 or 20 feet high, and garniſhed with large palmated or hand-ſhaped leaves. Of this are a number of varieties; as the common fig, a large, oblong, dark purpliſh blue fruit; which ripens in Auguſt either on ſtandards or walls, and the tree carries a great quantity of fruit. The brown or cheſnut fig; a large, globular, cheſnut-coloured fruit, having a purpliſh delicious pulp, ripening in July and Auguſt. The black iſchia fig; a middle-ſized, ſhortiſh, flat-crowned, blackiſh fruit, having a bright pulp; ripening in the middle of Auguſt. The green iſchia fig; a large, oblong, globular-headed, greeniſh fruit, ſlightly ſtained by the pulp to a reddiſh-brown colour; ripens in the end of Auguſt. The brown iſchia fig; a ſmall, pyramidal, browniſh-yellow fruit, having a purpliſh very rich pulp; ripening in Auguſt and September. The Malta fig; a ſmall flat-topped brown fruit, ripening in the middle of Auguſt or beginning of September. The round brown Naples fig; a globular, middle-ſized, light-brown fruit, and browniſh pulp; ripe in the end of Auguſt. The long, brown, Naples fig; a long dark-brown fruit, having a reddiſh pulp; ripe in September. The great blue fig; a large blue fruit, having a fine red pulp. The black Genoa fig; a large, pear-ſhaped, black-coloured fruit, with a bright red pulp; ripe in Auguſt.

2. The ſycamorus, or ſycamore of ſcripture. According to Mr. Haſſelquiſt, this is a huge tree, the ſtem being often 50 feet round. The tree is very common in the plains and fields of Lower Egypt. It buds in the latter end of March, and the fruit ripens in the beginning of June. It is wounded or cut by the inhabitants at the time it buds; for without this precaution, they ſay, it would not bear fruit.

3. The religioſa, or banian tree, is a native of ſeveral parts of the Eaſt Indies. It hath a wooden ſtem, branching 20 or 30 feet high, with heart-ſhaped entire leaves, ending in acute points. I is called by the Dutch, *devil's tree*; and by the inhabitants of Ceylon, *budughaha*, and *budughas*. *Buddu*, according to the tradition of theſe countries, was the name of the prophet who firſt taught the Indians under the grateful ſhade of this tree: for this reaſon, they not only give this ſpecies of fig a name commemorative of their prophet, but likewiſe pay it a particular veneration, by celebrating all their ſacrifices under its ſhade.

Culture. The carica is the ſpecies moſt frequently cultivated in this country, and the only one which does not require to be kept in a ſtove. It may be propagated either by ſuckers ariſing from the root, by layers, or by cuttings. The ſuckers are to be taken off as low down as poſſible; trim off any ragged part at bottom, leaving the tops entire, eſpecially if for ſtandards; and plant them in nurſery lines at two or three feet diſtance from each other, or they may at once be planted where they are to remain; obſerving, that if they are deſigned for walls or eſpaliers, they may be headed to ſix or eight inches in March, the more effectually to force out lateral ſhoots near the bottom; but, if intended for ſtandards, they muſt not be topped, but trained with a ſtem, not leſs than 15 or 18 inches for dwarf ſtandards, a yard for half-ſtandards, and four, five, or ſix feet for full ſtandards. Then they muſt be ſuffered to branch out to form a head; obſerving, that, whether againſt walls, eſpaliers, or ſtandards, the branches or ſhoots muſt never be ſhortened unleſs to procure a neceſſary ſupply of wood: for the fruit is always produced on the upper parts of the young ſhoots; and if theſe are cut off, no fruit can be expected. The beſt ſeaſon for propagating theſe trees by layers is in autumn; but it may be alſo done any time from October to March or April. Chooſe the young pliable lower ſhoots from the fruitful branches: lay them in the uſual way, covering the body of the layers three or four inches deep in the ground, keeping the top entire, and as upright as poſſible; and they will be rooted and fit to ſeparate from the parent in autumn; when they may be planted either in the nurſery, or where they are to remain, managing them as above directed. The time for propagating by cuttings is either in autumn at the fall of the leaf, or any time in March: chooſe well ripened ſhoots of the preceding ſummer; ſhort, and of robuſt growth, from about 12 to 15 inches long; having an inch or two of the two years wood at their baſe, the tops left entire; and plant them ſix or eight inches deep, in a bed or order of good earth, in rows two feet aſunder: and when planted in autumn, it will be eligible to protect their tops in time of hard froſt, the firſt winter, with any kind of long looſe litter.

Uſes. Figs are a conſiderable article in the materia medica, chiefly employed in emollient cataplaſms and pectoral decoctions. The beſt are thoſe which come from Turky. Many are alſo brought from the ſouth of France, where they prepare them in the following manner. The fruit is firſt dipped in ſcalding hot ley made of the aſhes of the fig tree, and then dried in the ſun. Hence theſe figs ſtick to the hands, and ſcour them like lixivial ſalts; and for the ſame reaſon they excite to ſtool, without griping. They are moderately nutrimental, grateful to the ſtomach, and eaſier to digeſt than any other of the ſweet fruits. They have been ſaid to produce lice, when eaten as a common food; but this ſeems to be entirely without foundation. The reaſon of this ſuppoſition ſeems to be, that in the countries where they grow naturally, they make the principal food of the poor people, who are generally troubled with theſe vermin. The wood of the ſycamore is not ſubject to rot; and has therefore been uſed for making of coffins, in which embalmed bodies were put. Mr. Haſſelquiſt affirms, that he ſaw in Egypt, coffins made of this kind of wood, which had been preſerved ſound for 2000 years.

FIDDLE. See VIOLIN.

FIDES, or FAITH, one of the virtues, deified by the Pagans. She had a temple near the capitol, founded by Numa Pompilius; but no animals were offered, or blood ſpilt, in her ſacrifices. During the performance of her rites, her prieſts appeared in white veſtments, with their heads and hands covered with linen, to ſhew that fidelity ought to be ſecret.

FIELD, in agriculture, a piece of ground incloſed, whether for tillage or paſture.

FIELD, in heraldry, is the whole ſurface of the ſhield, or the continent, ſo called becauſe it containeth thoſe atchievements anciently acquired in the field of battle. It is the ground on which the colours, bearings, metals, furs, charges, &c. are repreſented. Among the modern heralds, field is leſs frequently uſed in blazoning than ſhield or eſcutcheon. See the article SHIELD, &c.

FIELD *Book*, in ſurveying, that wherein the angles, ſtations, diſtances, &c. are ſet down.

FIELD *Colours*, in war, are ſmall flags of about a foot and half ſquare, which are carried along with the quarter-maſter general, for marking out the ground for the ſquadrons and battalions.

FIELD *Fare*, in ornithology. See TURDUS.

FIELD *Officers*, in the art of war. See OFFICER.

FIELD *Pieces*, ſmall cannons, from three to twelve pounders, carried along with an army in the field.

FIELD *Staff*, a weapon carried by the gunners, about the length of a halbert, with a ſpear at the end; having on each ſide ears ſcrewed on, like the cock of a match lock, where the gunners ſcrew in lighted matches, when they are upon command; and then the field ſtaffs are ſaid to be armed.

FIELD *Works*, in fortification, are thoſe thrown up by an army in beſieging a fortreſs, or by the beſieged to defend the place. Such are the fortifications of camps, highways, &c.

FIERI *Facias*, in law, a judicial writ, which lies at all times within the year and day, for him that hath recovered in an action of debt and damages: it is directed to the ſheriff, commanding him to levy the debt and damages on him, againſt whom the recovery was had.

FIFE, in muſic, a ſort of wind inſtrument, being a ſmall pipe.

FIFTH, in muſic, one of the harmonical intervals, or concords. See Syſtem of MUSIC.

FIG *Tree Cloth of Otaheite*, in the ſouth ſea, is a coarſe and harſh cloth, of the colour of the darkeſt brown paper, made of the bark of a tree which reſembles the wild fig-tree of the Weſt Indies. This cloth has the quality of reſiſting water; and the greater part of it is perfumed, and worn by the chiefs as a morning dreſs. For the method of manufacturing and colouring this cloth, ſee AOUTA. Hawksworth's Voyag. vol. ii. p. 210, &c.

FIGWORT, a plant, called by the botaniſts, Scrophularia.

FIGURATIVE, that which has a relation to figure, or that teaches under ſome obſcure reſemblance. Thus a figurative ſtyle is that which abounds in figures. The figurative ſtyle, F. Bouhours obſerves, is neither the moſt juſt, nor the beſt. For this reaſon Cicero directs us to the ancients, who not having yet bethought themſelves to uſe figurative expreſſions, but keeping to the moſt proper and natural way, have almoſt all wrote well. *Sunt enim illi veteres, qui nondum ornare poterant ea, que dicebant omnes prope præclare locuti.* Long uſe, ſay the grammarians, renders that proper in all languages, which at firſt was figurative. The ſame thoughts appear more lively when expreſſed by a figure, than when in ſimple terms. The reaſon is, that figurative expreſſions denote not only the principal matter, but alſo the emotion and paſſion of the perſon who ſpeaks.

FIGURATIVE is alſo much uſed in ſpeaking of the myſteries and figures of the old law. In this ſenſe manna is ſaid to be figurative of the euchariſt.

FIGURATIVE is alſo uſed in the Greek grammar for what we otherwiſe call characteriſtic, viz. a letter that characterizes certain tenſes of the Greek verbs; or that diſtinguiſhes and ſpecifies them. In the firſt conjugation of the Barytonous verbs, the φ is characteriſtic, or figurative of the præter tenſe, and the ψ of the future.

FIGURE, FIGURA, in a general ſenſe, denotes the ſurface or terminating extremes of a body. All bodies have ſome figure; whence, figurability is generally ranked among the eſſential properties of body or matter. A body without figure, would be an infinite body. The corpuſcular philoſophers account for every thing from the figure, bulks, and motions of the atoms, or primary corpuſcles of bodies. For the figures of bodies, conſidered as objects of ſight, ſee VISION.

FIGURES, in architecture and ſculpture, denote repreſentations of things made in ſolid matters; ſuch as ſtatues, &c. We ſay figures of braſs, of marble, of ſtucco, of plaiſter, &c. But in this ſenſe too, the term is more uſually applied to human repreſentations than to other things. Thus we ſay, an equeſtrian figure for a man on horſeback.

FIGURES, in arithmetic, are the numerical characters or the characters whereby numbers are expreſſed or written. Thus the number of four hundred and fifty is written, or expreſſed, by three figures, 450. The figures in arithmetic are the nine digets; 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0. See Syſtem of ARITHMETIC, Article I.

FIGURE, in dancing, denotes the ſeveral ſteps which the dancers make in order, and cadence; conſidered as they mark certain figures on the floor,

FIGURES, in fencing, are the divers guards, poſtures, attitudes or diſpoſitions, of the body, arm, or ſword. See Treatiſe on the Art of FENCING.

FIGURE, in fortification, is the plan of any fortified place; or interior polygon, &c. When the ſides and angles are equal, it is called a regular; when unequal, an irregular figure. See Treatiſe on the Art of FORTIFICATION.

FIGURE, in geometry, denotes a ſurface incloſed, or circumſcribed with one or more lines. Such are triangles, ſquares, polygons, circles, elipſes, &c. See Syſtem of GEOMETRY.

FIGURE, in grammar, is an expreſſion that deviates from the common and natural rules of grammar: either for the ſake of elegance or brevity.

The beſt grammarians only reckon four figures; the ELIPSIS, PLEONASM, SYLLEPSIS, and HYPERBATON. Others add: two more; viz. ANTIPTOSIS, and ENALAGE.

FIGURE, in compoſition. See ORATORY; alſo ALLEGORY, APOSTROPHE, HYPERBOLE, METAPHOR, PERSONIFICATION.

A FIGURE, *the Means or Inſtrument conceived to be the Agent.* When we ſurvey a number of connected objects, that which makes the greateſt figure employs chiefly our attention; and the emotion it raiſes, if lively, prompts us even to exceed nature in the conceptions we form of it.

A FIGURE, *which, among related Objects, extends the Properties of one to another.* This figure is not dignified with a proper name, becauſe it has been overlooked by writers. It merits, however, a place in this work; and muſt be diſtinguiſhed from the others elſewhere treated, as depending on a different principle. *Giddy brink, jovial wine, daring wound*, are examples of this figure. Here are adjectives that cannot be made to ſignify any quality of the ſubſtances to which they are joined: a brink, for example, cannot be termed giddy in a ſenſe, either proper or figurative, that can ſignify any of its qualities or attributes. When we examine attentively the expreſſion, we diſcover, that a brink is termed giddy from producing that effect in thoſe who ſtand on it: in the ſame manner, a wound is ſaid to be daring, not with reſpect to itſelf, but with reſpect to the boldneſs of the perſon who inflicts it: and wine is ſaid to be jovial, as inſpiring mirth and jollity. Thus the attributes of one ſubject are extended to another with which it is connected; and the expreſſion of ſuch a thought muſt be conſidered as a figure, becauſe the attribute is not applicable to the ſubject in any proper ſenſe.

How are we to account for this figure, which we ſee lies in the thought, and to what principle ſhall we refer it? Have poets a privilege to alter the nature of things, and at pleaſure to beſtow attributes upon a ſubject to which they do not belong? It is obſerved, that the mind paſſeth eaſily and ſweetly along a train of connected objects; and, where the objects are intimately connected, that it is diſpoſed to carry along the good or bad properties of one to another; eſpecially when it is in any degree inflamed with theſe properties. From this principle is derived the figure under conſideration. Language, invented for the communication of thought, would be imperfect, if it were not expreſſive even of the ſlighter propenſities and more delicate feelings: but language cannot remain ſo imperfect among a people who have received any poliſh; becauſe language is regulated by internal feeling, and is gradually improved to expreſs whatever paſſes in the mind. Thus, for example, when a ſword in the hand of a coward is termed a coward ſword, the expreſſion is ſignificative of an internal operation; for the mind, in paſſing from the agent to its inſtrument, is diſpoſed to extend to the latter the properties of the former. Governed by the ſame principle, we ſay liſtening fear, by extending the attribute liſtening of the man who liſtens, to the paſſion with which he is moved. In the expreſſion, *bold deed*, or *audax facinus*, we extend to the effect what properly belongs to the cauſe. But not to waſte time by making a commentary upon every expreſſion of this kind, the beſt way to give a complete view of the ſubject, is to exhibit a table of the different relations that may give occaſion to this figure. And in viewing the table, it will be obſerved, that the figure can never have any grace but where the relations are of the moſt intimate kind.

1. An attribute of the cauſe expreſſed as an attribute of the effect.

Audax facinus.
Of yonder fleet a *bold* diſcovery make.
An impious mortal gave the *daring* wound.
——————To my *advent'rous* ſong,
That with no middle flight intends to ſoar. *Paradiſe loſt.*

2. An attribute of the effect expreſſed as an attribute of the cauſe.

Quos periiſſe ambos *miſero* cenſebam in mari. *Plautus.*
No wonder, fallen ſuch a *pernicious* height. *Paradiſe loſt.*

3. An effect expreſſed as an attribute of the cauſe.

Jovial wine, Giddy brink, Drowſy night, Muſing midnight, Panting height, Aſtoniſh'd thought, Mournful gloom.

Caſting a dim *religious* light. MILTON, *Comus.*
And the *merry* bells ring round,
And the *jocund* rebecks ſound. MILTON, *Allegro.*

4. An attribute of a ſubject beſtowed upon one of its parts or members.

Longing arms.
It was the nightingale, and not the lark,
That pierc'd the *fearful* hollow of thine ear. *Romeo & Juliet, act* 3 *ſc* 7
——————Oh, lay by
Thoſe moſt ungentle looks and angry weapons;
Unleſs you mean my griefs and killing fears
Should ſtretch me out at your *relentleſs* feet. *Fair Penitent, act* 3.
——————And ready now
To ſtoop with *wearied* wing, and *willing* feet,
On the bare outſide of this world. *Paradiſe loſt, b.* 3.

5. A quality of the agent given to the inſtrument with which it operates.

Why peep your *coward* ſwords half out their ſhells?

6. An attribute of the agent given to the ſubject upon which it operates.

High-climbing hill. *Milton.*

7. A quality of one ſubject given to another.

Icci, *beatis* nunc Arabum invides
Gazis. *Horat. Carm. l.* 1. *ode* 29.
When ſapleſs age, and weak unable limbs,
Should bring thy father to his *drooping* chair. *Shakeſpear.*
Then, nothing loath, th' enamour'd fair he led,
And ſunk tranſported on the *conſcious* bed. *Odyſſey* viii. 337.

8. A circumſtance connected with a ſubject, expreſſed as a quality of the ſubject.

Breezy ſummit.
'Tis ours the chance of *fighting* fields to try. *Iliad* i. 301.
Oh! had I dy'd before that *well-fought* wall. *Odyſſey* v. 395.

From this table it appears, that the adorning a cauſe with an attribute of the effect, is not ſo agreeable as the oppoſite expreſſion. The progreſs from cauſe to effect is natural and eaſy: the oppoſite progreſs reſembles retrograde motion; and therefore *painting height*, *aſtoniſh'd thought*, are ſtrained and uncouth expreſſions, which a writer of taſte will avoid. It is not leſs ſtrained, to apply to a ſubject in its preſent ſtate, an epithet that may belong to it in ſome future ſtate:

Submerſaſque obrue puppes. *Æneid* i 73.
And mighty *ruins* fall. *Iliad* v. 411.
Impious ſons their *mangled* fathers wound.

Another rule regards this figure, That the property of one ſubject ought not to be beſtowed upon another with which that property is incongruous:

K. Rich.——————How dare thy joints forget
To pay their *awful* duty to our preſence? *Richard* III. *act* 3. *ſc.* 6.

The connection between an awful ſuperior and his ſubmiſſive dependent is ſo intimate, that an attribute may readily be transferred from the one to the other: but awfulneſs cannot be ſo transferred, becauſe it is inconſiſtent with ſubmiſſion.

Figure *of ſpeech*, as peculiarly diſtinguiſhed from the above and from thoſe firſt referred to.] Under the article **Metaphor** *and* **Allegory**, a figure of ſpeech is defined, "The uſing a word in a ſenſe different from what is proper to it;" and the new or uncommon ſenſe of the word is termed *the figurative ſenſe*. The figurative ſenſe muſt have a relation to that which is proper; and the more intimate the relation is, the figure is the more happy. How ornamental this figure is to language, will not be readily imagined by any one who hath not given peculiar attention; and therefore we ſhall endeavour to unfold its capital beauties and advantages. In the firſt place, a word uſed figuratively, or in a new ſenſe, ſuggeſts at the ſame time the ſenſe it commonly bears: and thus it has the effect to preſent two objects; one ſignified by the figurative ſenſe, which may be termed *the principal object*; and one ſignified by the proper ſenſe, which may be termed *acceſſory*: the principal makes a part of the thought; the acceſſory is merely ornamental. In this reſpect, a figure of ſpeech is preciſely ſimilar to concordant ſounds in muſic, which, without contributing to the melody, make it harmonious.

To explain the matter by examples. *Youth*, by a figure of ſpeech, is termed *the morning of life*: This expreſſion ſignifies *youth*, the principal object which enters into the thought, it ſuggeſts, at the ſame time, the proper ſenſe of *morning*: and this acceſſory object, being itſelf beautiful, and connected by reſemblance to the principal object, is not a little ornamental. *Imperious ocean* is an example of a different kind, where an attribute is expreſſed figuratively: Together with *ſtormy*, the figurative meaning of the epithet *imperious*, there is ſuggeſted its proper meaning, viz. the ſtern authority of a deſpotic prince; and theſe two are ſtrongly connected by reſemblance. Upon this figurative power of words, Vida deſcants with elegance, *Poet. lib.* iii. 44.

In the next place, this figure poſſeſſes a ſignal power of aggrandiſing an object, by the following means. Words, which have no original beauty but what ariſes from their ſound, acquire an adventitious beauty from their meaning: a word ſignifying any thing that is agreeable, becomes by that means agreeable; for the agreeableneſs of the object is communicated to its name. This acquired beauty, by the force of cuſtom, adheres to the word even when uſed figuratively; and the beauty received from the thing it properly ſignifies, is communicated to the thing which it is made to ſignify figuratively. Conſider the foregoing expreſſion *Imperious ocean*, how much more elevated it is than *Stormy ocean*.

Thirdly, This figure hath a happy effect by preventing the familiarity of proper names. The familiarity of a proper name, is communicated to the thing it ſignifies by means of their intimate connection; and the thing is thereby brought down in our feeling. This bad effect is prevented by uſing a figurative word inſtead of one that is proper; as, for example, when we expreſs the ſky by terming it *the blue vault of heaven*; for though no work of art can compare with the ſky in grandeur, the expreſſion however is reliſhed, becauſe it prevents the object from being brought down by the familiarity of its proper name.

Laſtly, By this figure, language is enriched, and rendered more copious; in which reſpect, were there no other, a figure of ſpeech is a happy invention. This property is finely touched by Vida; *Poet. lib.* iii. 90. The beauties we have mentioned belong to every figure of ſpeech. Several other beauties peculiar to one or other ſort, we ſhall have occaſion to remark afterward. Not only ſubjects, but qualities, actions, effects, may be expreſſed figuratively. Thus, as to ſubjects, *the gates of breath* for the lips, *the watery kingdom* for the ocean. As to qualities, *fierce* for ſtormy, in the expreſſion *Fierce winter*; *altus* for profundus, *Altus puteus*, *Altum mare*; *breathing* for perſpiring, *breathing plants*. Again, as to actions, The ſea *rages*, Time will *melt* her frozen thoughts, Time *kills* grief. An effect is put for the cauſe, as *lux* for the ſun; and a cauſe for the effect, as *boum labores* for corn. The relation of reſemblance is one plentiful ſource of figures of ſpeech; and nothing is more common than to apply to one object the name of another that reſembles it in any reſpect: Height, ſize, and worldly greatneſs, reſemble not each other; but the emotions they produce reſemble each other, aud promoted by this reſemblance, we naturally expreſs worldly greatneſs by height or ſize.

For epitomiſing this ſubject, and at the ſame time giving a clear view of it, we ſhall add a liſt of the ſeveral relations upon which figures of ſpeech are commonly founded. This liſt we ſhall divide into two tables; one of ſubjects expreſſed figuratively, and one of attributes.

TABLE I. *Subjects expreſſed figuratively.*

1. A word proper to one ſubject employed figuratively to expreſs a reſembling ſubject. There is no figure of ſpeech ſo frequent, as what is derived from the relation of reſemblance. Youth, for example, is ſignified figuratively by the morning of life. The life of a man reſembles a natural day in ſeveral particulars; the morning is the beginning of a day, youth the beginning of life; the morning is cheerful, ſo is youth, &c. By another reſemblance, a bold warrior is termed the thunder-bolt of war; a multitude of troubles, a ſea of troubles. This figure, above all others, affords pleaſure to the mind by variety of beauties. Beſides the beauties above-mentioned, common to all ſorts, it poſſeſſes in particular the beauty of a metaphor or of a ſimile: a figure of ſpeech built upon reſemblance, ſuggeſts always a compariſon between the principal ſubject and the acceſſory; whereby every good effect of a metaphor or ſimile, may, in a ſhort and lively manner, be produced by this figure of ſpeech.

2. A word proper to the effect employed figuratively to expreſs the cauſe.

Lux for the ſun; *Shadow* for cloud. A helmet is ſignified by the expreſſion *glittering terror*; a tree by *ſhadow* or *umbrage*. Hence the expreſſion:

Nec habet Pelion umbras. *Ovid.*
Where the dun umbrage hangs. *Spring, l.* 1023.

A wound is made to ſignify an arrow:

Vulnere non pedibus te conſequar. *Ovid.*

There is a peculiar force and beauty in this figure: the word which ſignifies figuratively the principal ſubject, denotes it to be a cauſe by ſuggeſting the effect.

3. A word proper to the cauſe, employed figuratively to expreſs the effect. *Boumque labores* for corn. *Sorrow* or *grief* for tears.

Again Ulyſſes veil'd his penſive head;
Again unmann'd, a ſhower of *ſorrow* ſhed.
Streaming *Grief* his faded cheek bedew'd.

There is a peculiar energy in this figure, ſimilar to that in the former: the figurative name denotes the ſubject to be an effect, by ſuggeſting its cauſe.

4. Two things being intimately connected, the proper name of the one employed figuratively to ſignify the other. *Day* for light. *Night* for darkneſs; and hence, A ſudden night. *Winter* for a ſtorm at ſea:

Interea magno miſceri murmure pontum,
Emiſſamque Hyemem ſenſit Neptunus. *Ænied.* i. 128.

This laſt figure would be too bold for a Britiſh writer, as a ſtorm at ſea is not inſeparably connected with winter in this climate.

5. A word proper to an attribute, employed figuratively to denote the ſubject. *Youth* and *beauty* for thoſe who are young and beautiful.

Youth and beauty ſhall be laid in duſt.

Majeſty for the king:

What art thou, that uſurp'ſt this time of night,
Together with that fair and warlike form
In which the *Majeſty* of buried Denmark
Did ſometime march? *Hamlet, act* 1. *ſc.* 1.
———Or have ye choſen this place
After the toils of battle, to repoſe
Your weari'd *virtue*. *Paradiſe loſt.*

Verdure for a green field. *Summer, l.* 301.

Speaking of cranes,

The pigmy nations wounds and death they bring,
And all the *war* deſcends upon the wing. *Iliad* iii. 10.
Cool *age* advances venerably wiſe. *Iliad* iii. 149.

The peculiar beauty of this figure ariſes from ſuggeſting an attribute that embelliſhes the ſubject, or puts it in a ſtronger light.

6. A complex term employed figuratively to denote one of the component parts. *Funus* for a dead body. *Burial* for a grave.

7. The name of one of the component parts inſtead of the complex term. *Tæda* for a marriage. The *Eaſt* for a country ſituated eaſt from us. *Jovis veſtigia ſervat* for imitating Jupiter in general.

8. A word ſignifying time or place, employed figuratively to denote what is connected with it. *Clime* for a nation, or for a conſtitution of government: hence the expreſſion, *Merciful clime, Fleecy winter* for ſnow, *Seculum felix.*

9. A part of the whole. The *head* for the perſon.

Triginta minas pro *capite* tuo dedi. *Plautus.*
Thy growing virtues juſtify'd my cares,
And promis'd comfort to my *ſilver hairs* *Iliad* ix. 616.

The peculiar beauty of this figure conſiſts in marking that part which makes the greateſt figure.

10. The name of the container, employed figuratively to ſignify what is contained. *Grove* for the birds in it, Vocal *grove. Ships* for the ſeamen, Agonizing *ſhips. Mountains* for the ſheep paſturing upon them, Bleating *mountains. Zacynthus, Ithaca,* &c. for the inhabitants. *Ex mæſtis domibus,* Livy.

11. The name of the ſuſtainer, employed figuratively to ſignify what is ſuſtained. *Altar* for the ſacrifice. *Field* for the battle fought upon it, Well-fought *field.*

12. The name of the materials, employed figuratively to ſignify the things made of them. *Ferrum* for *gladius.*

13. The names of the Heathen deities, employed figuratively to ſignify what they patroniſe. *Jove* for the air, *Mars* for war, *Venus* for beauty, *Cupid* for love, *Ceres* for corn, *Neptune* for the ſea, *Vulcan* for fire. This figure beſtows great elevation upon the ſubject; and therefore ought to be confined to the higher ſtrains of poetry.

TABLE II. *Attributes expreſſed figuratively.*

When two attributes are connected, the name of the one may be employed figuratively to expreſs the other. Purity and virginity are attributes of the ſame perſon: hence the expreſſion, *Virgin* ſnow, for pure ſnow.

2. A word ſignifying properly an attribute of one ſubject, employed figuratively to expreſs a reſembling attribute of another ſubject. *Tottering* ſtate. *Imperious* ocean. *Angry* flood. *Raging* tempeſt. *Shallow* fears.

My ſure divinity ſhall bear the ſhield,
And edge thy ſword to *reap* the glorious field. *Odyſſey* xx. 61.

Black omen, for an omen that pretends bad fortune.

Ater odor *Virgil.*

The peculiar beauty of this figure ariſes from ſuggeſting a compariſon.

3. A word proper to the ſubject, employed to expreſs one of its attributes. *Mens* for *intellectus. Mens* for a reſolution:

Iſtam, oro exue mentem.

4. When two ſubjects have a reſemblance by a common quality, the name of the one ſubject may be employed figuratively to denote that quality in the other: *Summer* life for agreeable life.

5. The name of the inſtrument made to ſignify the power of employing it.

———Melpomene, cui liquidam pater
Vocem cum *cithara* dedit.

The ample field of figurative expreſſion diſplayed in theſe tables, affords great ſcope for reaſoning. Several of the obſervations relating to metaphor, are applicable to figures of ſpeech: theſe ſhall be ſlightly retouched, with ſome additions peculiarly adapted to the preſent ſubject.

1. As the figure under conſideration is built upon relation, we find from experience, and it muſt be obvious from reaſon, that the beauty of it depends on the intimacy of the relation between the figurative and proper ſenſe of the word. A ſlight reſemblance, in particular, will never make this figure agreeable: the expreſſion, for example, *Drink down a ſecret,* for liſtening to a ſecret with attention, is harſh and uncouth, becauſe there is ſcarce any reſemblance between *liſtening* and *drinking.* The expreſſion *weighty crack,* uſed by Ben Johnſon for *loud crack,* is worſe if poſſible: a loud ſound has not the ſlighteſt reſemblance to a piece of matter that is weighty.

Phemius! let acts of gods, and heroes old,
What ancient bards in hall and bow'r have told,
Attemper'd to the lyre, your voice employ,
Such the pleas'd *ear will drink* with ſilent joy. *Odyſſey* i. 433.

The following figures of ſpeech ſeem altogether wild and extravagant, the figurative and proper meaning having no connection whatever. *Moving* ſoftneſs, freſhneſs *breathes, Breathing* proſpect, *Flowing* ſpring, *Dewy* light, *Lucid* coolneſs, and many others of this falſe coin, may be found in Thomſon's *Seaſons.*

2. The proper ſenſe of the word ought to bear ſome proportion to the figurative ſenſe, and not ſoar much above it, nor ſink much below it. This rule, as well as the foregoing, is finely illuſtrated by Vida, *Poet.* iii. 148.

3. In a figure of ſpeech, every circumſtance ought to be avoided that agrees with the proper ſenſe only, not with the figurative ſenſe; for it is the latter that expreſſes the thought, and the former ſerves for no other purpoſe but to make harmony:

Zacynthusgreen with ever-ſhady groves,
And Ithaca, preſumptuous boaſt their loves;
Obtruding on my choice a ſecond lord,
They preſs the Hymenean rite abhorr'd. *Odyſſey,* xix. 152.

Zacynthus here ſtanding figuratively for the inhabitants, the deſcription of the iſland is quite out of place: it puzzles the reader, by making him doubt whether the word ought to be taken in its proper or figurative ſenſe.

———Write, my queen,
And with mine eyes I'll drink the words you ſend,
Though ink be made of gall. *Cymbeline, act* 1. *ſc.* 2.

The diſguſt one has to drink ink in reality, is not to the purpoſe where the ſubject is drinking ink figuratively.

4. To draw conſequences from a figure of ſpeech, as if the word were to be underſtood literally, is a groſs abſurdity; for it is confounding truth with fiction:

Be Moubray's ſins ſo heavy in his boſom,
That they may break his foaming courſer's back,
And throw the rider headlong in the liſts,
A caitiff recreant to my couſin Hereford. *Richard* II. *act* 1. *ſc.* 3.

Sin may be imagined heavy in a figurative ſenſe: but weight in a proper ſenſe belongs to the acceſſory only; and therefore to deſcribe the effects of weight, is to deſert the principal ſubject, and to convert the acceſſory into a principal:

Cromwell. How does your Grace?
Wolſey. Why, well;
Never ſo truly happy, my good Cromwell.
I know myſelf now, and I feel within me
A peace above all earthly dignities,
A ſtill and quiet conſcience. The King has cur'd me,
I humbly thank his Grace; and, from theſe ſhoulders,
Theſe ruin'd pillars, out of pity, taken
A load would ſink a navy, too much honour. *Henry* VIII. *act* 3. *ſc.* 6.

How long a ſpace, ſince firſt I lov'd, it is!
To look into a glaſs I fear,
And am ſurpris'd with wonder, when I miſs,
Grey hairs and wrinkles there. *Cowley, vol.* 1. *p.* 86.

I choſe the flouriſhing'ſt tree in all the park,
With freſheſt boughs, and faireſt head:
I cut my love into his gentle bark,
And in three days behold 'tis dead;
My very written flames ſo violent be,
They've burnt and wither'd up the tree. *Cowley, vol.* 1. *p.* 136.

Such a play of words is pleaſant in a ludicrous poem.

Almeria. O Alphonſo, Alphonſo!
Devouring ſeas have waſh'd thee from my ſight,
No time ſhall raſe thee from my memory;
No, I will live to be thy monument:
The cruel ocean is no more thy tomb:
But in my heart thou art interr'd. *Mourning Bride, act* 1. *ſc.* 1.

This would be very right, if there were any inconſiſtence, in being interred in one place really, and in another place figuratively. From conſidering, that a word uſed in a figurative ſenſe ſuggeſts at the ſame time its proper meaning, we diſcover a fifth rule, That we ought not to employ a word in a figurative ſenſe, the proper ſenſe of which is inconſiſtent or incongruous with the ſubject; for every inconſiſtency, and even incongruity, though in the expreſſion only, and not real, is unpleaſant:

Interea genitor Tyberini ad fluminis undam
Vulnera *ſiccabat* lymphis———

The foregoing rule may be extended to form a ſixth, That no epithet ought to be given to the figurative ſenſe of a word that agrees not alſo with its proper ſenſe:

Parcus deorum cultor, et infrequens,
Inſanientis dum ſapientiæ
Conſultus erro. *Horat Carm. l.* 1. *ode* 54.

Seventhly, The crowding into one period or thought different figures of ſpeech, is not leſs faulty than crowding metaphors in that manner: the mind is diſtracted in the quick tranſition from one image to another, and is puzzled inſtead of being pleaſed:

I am of ladies moſt deject and wretched,
That ſuck'd the honey of his muſic vows. *Hamlet.*
My bleeding boſom ſickens at the ſound. *Odyſſey* i. 439.

Eighthly, If crowding figures be bad, it is ſtill worſe to graft one figure upon another; For inſtance,

While his keen falchion drinks the warriors lives. *Iliad.* xi. 211.

A falchion drinking the warriors blood is a figure built upon reſemblance, which is paſſable. But then in the expreſſion lives is again put for blood; and by thus grafting one figure upon another, the expreſſion is rendered obſcure and unpleaſant.

Ninthly, Intricate and involved figures, that can ſcarce be analyſed, or reduced to plain language, are leaſt of all tolerable:

Votis incendimus aras. *Æneid.* iii. 279.
Elſe ſhall our fates be number'd with the dead. *Iliad* v. 294.
Commutual death the fate of war confounds. *Iliad* viii. 85.

Speaking of Proteus.

Inſtant he wears, eluſive of the rape,
The mimic force of every ſavage ſhape. *Odyſſey* iv. 563.
Rolling convulſive on the floor, is ſeen
The piteous object of a proſtrate queen. *Ibid.* iv. 652.

In the tenth place, When a ſubject is introduced by its proper name, it is abſurd to attribute to it the properties of a different ſubject to which the word is ſometimes applied in a figurative ſenſe:

Hear me, O Neptune! thou whoſe arms are hurl'd
From ſhore to ſhore and gird the ſolid world. *Odyſſey* ix. 617.

Neptune is here introduced perſonally, and not figuratively for the ocean; the deſcription therefore, which is only applicable to the latter, is altogether improper. It is not ſufficient, that a figure of ſpeech be regularly conſtructed, and be free from blemiſh: it requires taſte to diſcern when it is proper, when improper; and taſte perhaps is our only guide. One, however, may gather from reflections and experience, that ornaments and graces ſuit not any of the diſpiriting paſſions, nor are proper for expreſſing any thing grave and important. In familiar converſation, they are in ſome meaſure ridiculous; Proſpero, in the *Tempeſt*, ſpeaking to his daughter Miranda, ſays,

> The fringed curtains of thine eyes advance,
> And ſay what thou ſeeſt yond.

No exception can be taken to the juſtneſs of the figure: and circumſtances may be imagined to make it proper; but it is certainly not proper in familiar converſation. In the laſt place, Though figures of ſpeech have a charming effect when accurately conſtructed and properly introduced, they ought, however, to be ſcattered with a ſparing hand: nothing is more luſcious, and nothing conſequently more ſatiating, than redundant ornaments of any kind.

Figure, in painting and deſigning, denotes the lines and colours, which form the repreſentation of a man, or other animal. But the term figure is in a more immediate and peculiar manner underſtood of human perſonages: thus, a painting is ſaid to be full of figures, when it abounds with repreſentations of men.

Figure is alſo applied to repreſentations, or images of things in prints, &c. Some readers chuſe to have the figures, eſpecially the mathematical ones, in wood, for the convenience of having them immediately annexed to the matter they refer to: others rather chuſe to be at the pains of turning over, and having recourſe to another part of the book, that they may have the figures more neat and accurate on copper. **Figure**, in rhetoric, is a phraſe, or turn of ſpeech or diſcourſe, more beautiful and emphatical than what is uſed in common or ordinary ſpeaking.

Figures *of Sentences*, ſome are principally adapted for reaſoning and inſtruction, and others to move the paſſions. Among the ancients, Demoſthenes is moſt celebrated for expreſſing the force and energy of the former, and Iſocrates excelled in the beauties and delicacies of the latter. Cicero lays ſo great ſtreſs on theſe figures, that he repreſents them as the brighteſt parts of oratory; and makes the power and efficacy of the art to depend in a great meaſure on a thorough knowledge and application of them.

Figure is uſed, in theology, for the myſteries repreſented or delivered obſcurely to us under certain types or actions in the Old Teſtament. Thus manna is held a figure or type of the eucharist; and the death of Abel a figure of the ſuffering of Chriſt. Many divines and critics contend, that all the actions, hiſtories, ceremonies, &c. of the Old Teſtament, are only figures, types, and prophecies, of what was to happen under the New. The Jews are ſuppoſed to have had the figures or ſhadows, and we the ſubſtance.

FIGURED, in general, ſomething marked with figures. The term figured is chiefly applied to ſtuffs, whereon the figures of flowers, and the like, are either wrought or ſtamped.

FILAMENT, in anatomy, natural hiſtory, &c. a term uſed in the ſame ſenſe with fibre, for thoſe fine threads whereof the fleſh, nerves, ſkin, plants, roots, &c. are compoſed.

Vegetable **Filaments** form a ſubſtance of great uſe in the arts and manufactures; furniſhing thread, cloth, cordage, &c. For theſe purpoſes the filamentous parts of the cannabis and linum, or hemp and flax, are employed among us. But different vegetables have been employed in different countries for the ſame uſes. Putrefaction deſtroys the pulpy or fleſhy matter, and leaves the tough filaments entire: by curiouſly putrefying the leaf of a plant in water, we obtain the fine flexile fibres, which conſtituted the baſis of the ribs and minute veins, and which now form as it were a ſkeleton of the leaf. Alkaline lixivia, in ſome degree, produce ſimilar effects to putrefaction.

The ſieur de Flacourt, in his hiſtory of Madagaſcar, relates, that different kinds of cloth are prepared in that iſland, from the filaments of the bark of certain trees boiled in ſtrong ley; that ſome of theſe cloths are very fine, and approach to the ſoftneſs of ſilk, but in durability come ſhort of cotton; that others are coarſer and ſtronger, and laſt thrice as long as cotton; and that of theſe the ſails and cordage of his veſſel were made. The ſame author informs us, that the ſtalks of nettles are uſed for the like purpoſes in his own country, France. And Sir Hans Sloane relates, in one of his letters to Mr. Ray, that he has been informed by ſeveral, that muſlin and callico, and moſt of the Indian linens, are made of nettles.

In ſome of the Swediſh provinces, a ſtrong kind of cloth is ſaid to be prepared from hop-ſtalks: and in the tranſactions of the Swediſh academy for the year 1750, there is an account of an experiment made in conſequence of that report. Of the ſtalks, gathered in autumn, about as many were taken, as equalled in bulk a quantity of flax that would have produced a pound after preparation. The ſtalks were put into water, and kept covered therewith during the winter. In March they were taken out, dried in a ſtove, and dreſſed as flax. The prepared filaments weighed nearly a pound, and proved fine, ſoft, and white: they were ſpun and woven into ſix ells of fine ſtrong cloth. The author, Mr. Shiſler, obſerves, that hop-ſtalks take much longer time to rot than flax; and that, if not fully rotted, the woody part will not ſeparate, and the cloth will neither prove white nor fine. Hemp, flax, and all other vegetable filaments, and thread or cloth prepared from them, differ remarkably from wool, hair, ſilk, and other animal productions, not only in the principles into which they are reſoluble by fire, but likewiſe in ſome of their more intereſting properties, particularly in their diſpoſition to imbibe colouring matters; ſundry liquors, which give a beautiful and durable dye to thoſe of the animal, giving no ſtain at all to thoſe of the vegetable kingdom.

Many other inſtances of this kind are known too well to the callico printer; whoſe grand deſideratum it is, to find means of making linen receive the ſame colours that wool does. The phyſical cauſe of the difference is wholly unknown; and indeed, of the theory of dyes in general, we know as yet extremely little. There are many inſtances of a like diverſity, even in the metallic kingdom, where a mechanical difference in texture can ſcarcely be preſumed to be the cauſe: thus ſilver receives a deep ſtain from ſulphureous or putrid vapours, or the yolk of a boiled egg, which have no effect upon tin.

Filaments, among botaniſts, particularly ſignify the ſtamina.

FILAZER, **Filacer**, **Filizer**, an officer in the court of common pleas, ſo called becauſe he files the writs whereon he makes out proceſs. Of theſe there are ſixteen in the ſeveral diviſions and counties of England.

FILBERT, or **Filberd**, the fruit of the corylus, or hazel. See **Corylus**.

FILE, among mechanics, a tool uſed in metal, &c. in order to ſmooth, poliſh, or cut. This inſtrument is of iron or forged ſteel, cut in little furrows, with chiſſels and a mallet, this and that way, and of this or that depth, according to the grain or touch required. After cutting the file, it muſt be tempered with a compoſition of chimney-ſoot, very hard and dry, diluted and wrought up with urine, vinegar, and ſalt; the whole being reduced to the conſiſtence of muſtard. Tempering the files conſiſts in rubbing them over with this compoſition, and covering them in loam; after which they are put in a charcoal fire, and taken out by that time they have acquired a cherry colour, which is known by a ſmall rod of the ſame ſteel put in along with them. Being taken out of the fire, they are thrown into cold ſpring water: and when cold, they are cleaned with charcoal and a rag; and being clean and dry, are kept from ruſt by laying them up in wheat bran. Iron files require more heating than ſteel ones. Files are of different forms, ſizes, cuts, and degrees of fineneſs, according to the different uſes and occaſions for which they are made. See **Filing**.

File, in law, a thread, ſtring or wire, upon which writs and other exhihits in courts and offices are faſtened or filed, for the more ſafe keeping, and ready turning to the ſame. A file is a record of the court; and the filing of a proceſs of a court makes it a record of it. An original writ may be filed after judgment given in the cauſe, iſſued forth before; declarations, &c. are to be filed, and affidavits muſt be filed, ſome before they are read in court, and ſome preſently when read in court. Before filing a record removed by certiorari, the juſtices of B. R. may refuſe to receive it, if it appears to be for delay, &c. and remand it back for the expedition of juſtice: but if the certiorari be once filed, the proceedings below cannot be revived. An indictment, &c. cannot be amended after it is filed.

File, in a military ſenſe, is a row of men ſtanding one behind or below another from front to rear. Or, file is a line or ſeries of ſoldiers, placed one before another, and thus compoſing the depth of a battalion or ſquadron. The files which bind the right and left are called the flanks. They ſay, *cloſe the files*; that is, bring the men nearer each other. *Double the files*; that is double the depth of the battalion, and diminiſh its breadth or front by one half. The laſt or hindermoſt perſon is ſaid *to bring up the file*. *To file off*, is to wheel off from marching in a ſpacious front, and to march in length by files.

FILIAL, ſomething belonging to the relation of a ſon. The divines uſually diſtinguiſh between a ſervile and a filial fear. The moſt abandoned have a ſervile fear of God, ſuch as that of a ſlave to his maſter; but not a filial fear, i. e. a fear reſulting from love and reſpect.

FILICES, (from *filum*, a thread, *quaſi filatim inciſa*), Ferns; one of the ſeven tribes or families, of the vegetable kingdom, according to Linnæus, by whom it is thus characterized: "having their fructification on the back ſide of the frondes." They conſtitute the firſt order in the claſs cryptogamia; and conſiſt of 16 genera, which are divided into *fructificationes ſpicatæ*, *frondoſæ*, *&* *radicales*. See Syſtem of **Botany**, Plate VI. Claſs 24. Order I.

FILING, one of the principal operations in ſmithery, &c. ſucceeding to forging. The coarſer cut files are always to be ſucceeded by finer; and in all the kinds the rule is tolean heavy on the file in thruſting it forward, becauſe the teeth of the file are made to cut forwards; but in drawing the file back again for a ſecond ſtroke, it is to be lightly lifted juſt above the work, becauſe it cuts not coming back. The rough or coarſe toothed file (which, when large, is called a rubber) ſerves to take off the unevenneſſes of the work left by the hammer in forging. The baſtard toothed file is to take out the too deep cuts and file ſtrokes made by the rough file; the fine toothed file takes out the cuts or file ſtrokes the baſtard file made; and laſtly, the ſmooth file thoſe left by the fine file. In this order the files of ſeveral cuts are to ſucceed each other till the work is as ſmooth as it can be filed; after which it may be made yet ſmoother with emery, tripoli, &c. See POLISHING.

To FILL, in the ſea-language, is to brace the ſails in ſuch a manner, that the wind entering their cavities from behind, dilates them, ſo as to advance the ſhip in her courſe, after the ſails had been for ſome time ſhivering or braced back.

FILLET, or FILET, in architecture, denotes a little ſquare member or ornament uſed in divers places and on divers occaſions, but generally as a ſort of corona over a greater moulding.

FILLET, *teniola*, in heraldry, a kind of orle or bordure, containing only a third or fourth part of the breadth of the common bordure. It is ſuppoſed to be withdrawn inwards, and is of a different colour from the field. It runs quite round near the edge, as a lace over a cloak.

FILLIGREE *Work*, a kind of enrichment on gold or ſilver, wrought delicately, in manner of little threads or grains, or both intermixed. We have vaſes, &c. of filligree work. The term has been lately applied, to ornamental works, formed, as fancy directs, of ſtrips of paper, differently coloured, rolled into various figures, and artfully combined.

FILLY, a term among horſe-dealers, to denote the female or mare colt. See FOAL.

FILM, a thick ſkin or pellicle. In plants it is often uſed for that thin woody ſkin which ſeparates the ſeeds in the pods, and keeps them apart.

FILM, or HUMOUR, in the eye of a horſe. For the cure, ſee Syſtem of FARRIERY, Claſs XI, Sect. XXIX.

FILTER, or FILTRE, in chymiſtry, &c. a piece of woollen cloth, linen, paper, or other matter, ſome of which are in the form of hollow inverted cones, uſed to filtrate or ſtrain liquors through.

FILTRATION, the act of paſſing any liquor through a filtre, called alſo *colature*, *percolation*, and *tranſcolation*. See Syſtem of CHYMISTRY, Part II.

FILTRUM, in natural hiſtory, the name of a ſtone much in uſe in the eaſtern parts of the world, and ſometimes with us for the filtrating of water intended for drinking. The Japoneſe are extremely fond of this ſtone, and impute their uninterrupted health, and particularly their being always free from the ſtone and gravel, to their drinking the water thus cleared of all its heterogeneous and miſchievous particles. The people of this, and many other places thereabouts, have a ſettled opinion, that moſt diſeaſes ariſe from impurities of water, and are well aſſured, that theſe impurities are all lodged in the ſtone filtre, and left behind by the water in its paſſage. The manner of uſing the ſtone is this; they form a ſort of mortars with very thick bottoms out of the largeſt pieces of it, and the water is poured into theſe, and the ſtone being of a very lax and ſpungy texture, it ſoon makes its way through, and is received into a veſſel placed underneath for that purpoſe. It being found, therefore, an eaſy thing for us to have our water filtered in the ſame manner that the Japoneſe have, it remains to try whether it will have all thoſe ſalutary effects which the people of that part of the world give it; and this ſeems not to be imagined from reaſon and analogy. We very well know that water is frequently impregnated with ſaline particles, and that it alſo frequently diſſolves by this means earthly and other matters which it otherwiſe could not do. But we alſo know, that ſalts diſſolved in water are not to be ſeparated by filtration; and it is equally certain, that earthy, ſparry, or other matter, that is ſuſpended in water when clear, will in like manner paſs through the filtre with it. Upon the whole, we are happy enough to have no occaſion for filtering ſtones, ſince our ſprings and rivers afford us water already pure enough to our hands; and in places where this is not the caſe, it is always poſſible to ſave rain water, which will keep a long time with proper management, and is much purer than all the art in the world can make ſuch as has once been foul. Valentini Muſæum Muſæorum, lib. i. cap. 22. The only inſtance in which a filtering ſtone can be of real uſe, is, when there is no water to be had but that of ſome muddy river; in this caſe, the mud being a foreign body not diſſolved in, but only floating among the water, it will be left behind in its paſſing the cloſe ſtructure in the filtre; but this is always to be as well obtained by letting it ſtand a while to ſubſide.

FIMBRIATED, a term in heraldry, ſignifving that an ordinary is edged round with another of a different colour. Thus, he beareth, or, a croſs-pattee gules, fimbriated ſable.

FIN, in natural hiſtory, a well known part of fiſhes, conſiſting of a membrane ſupported by rays, or little bony or cartilaginous oſſicles. The office of the fins has commonly been ſuppoſed to be analogous to that of the feathers in fowls; and to aſſiſt the fiſh in its progreſſive motion, or ſwimming: but the latter naturaliſts find this a miſtake. The tail is a great inſtrument of ſwimming: the fins only ſerve to keep the fiſh upright, and prevent vacillation or wavering.

Whale FINS, are commonly taken for that part of the whale which the populace call whale bone; but whence the miſtake ſhould ariſe is not eaſy to determine. Theſe whale fins, as ſome have erroneouſly called them, are the moſt valuable part of the animal. See *Whale* FISHERY and WHALE *Bone*.

FINAL, that which terminates or comes laſt in any thing, as a final judgment, final ſentence, &c.

FINAL *Cauſe*, is the end for which the thing is done. The final cauſe is the firſt thing in the intention of a perſon who does a thing; and the laſt, in the execution.

FINAL *Letters* are thoſe which cloſe words. The Hebrews have five final letters, which when at the end of a word have a different figure from what they have at the beginning or in the middle thereof. Theſe are the ך, ם, ן. ף. ץ, *caph*, *mem*, *nun*, *pe*, *tſade*, which every where but at the end of words, are wrote כ, מ, נ, פ, צ.

FINANCES, in the French polity, denote the revenues of the king and ſtate; much the ſame with the treaſury or exchequer of the Engliſh, and the fiſcus of the Romans.

Council of the FINANCES, correſponds to our lords commiſſioners of the treaſury; the comptroller general of the finances, to our lord high treaſurer, &c.

FINANCES *Britiſh*. See FUND.

FINCH, in ornithology, the Engliſh name of a ſpecies of birds, belonging to the genus fringilla. See FRINGILLA.

FINE, in law, hath divers applications. Sometimes it is uſed for a formal conveyance of lands or tenements, or of any thing inheritable, being *in eſſe temporis finis*, in order to cut off all controverſies. Others define it to be a final agreement between perſons concerning any lands or rents, &c. of which any ſuit or writ, is depending between them in any court.

FINE, ſometimes ſignifies a ſum of money paid for entering lands or tenements let by leaſe; and ſometimes a pecuniary mulct for an offence committed againſt the king and his laws, or againſt the lord of the manor.

FINES *for Alienation*, in feodal law. One of the attendants or conſequences of tenure by vaſſalſhip. *Knight ſervice*, was that of fines due to the lord for every alienation, whenever the tenant had occaſion to make over his land to another. See FEE.

FIR *Tree*, in botany. See ABIES.

FIRE is that ſubtile, inviſible, ſubſtance, by which all bodies are expanded, or enlarged in their dimenſions, and then become hot to the touch; fluid ſubſtances of every kind are carried off in vapour; ſolid bodies become luminous, and are likewiſe diſſipated in vapour, or, if incapable of being evaporated, become fluid, and at laſt are converted into glaſs. It ſeems likewiſe to be the chief agent in nature, on which animal and vegetable life have an immediate dependence, and without which it doth not appear that the ſyſtem of nature itſelf could ſubſiſt a ſingle moment.

No queſtion in natural philoſophy ſeems more difficult to be reſolved than that concerning the nature of fire, and none has been more agitated. One ſet of philoſophers, amongſt whom are Lord Bacon, Sir Iſaac Newton, &c. aſſert, that fire is not any ſubſtance of itſelf diſtinct from terreſtrial bodies, but that it conſiſts only in a vehement vibratory motion of their parts. Hence lord Bacon defines heat, by which he means fire itſelf, to be "an expanſive undulatory motion in the minute particles of a body, whereby they tend with ſome rapidity towards the circumference, and at the ſame time tend a little upwards." From this he infers, that if in any natural body you can excite a motion whereby it ſhall expand or dilate itſelf, and can repreſs and direct this motion upon itſelf in ſuch a manner that the motion ſhall not proceed uniformly, but obtain in ſome parts and be checked in others, you will generate heat, or fire.

Sir Iſaac Newton conjectures, that the ſun and ſtars are only great earths vehemently heated: for large bodies, he obſerves, preſerves their heat the longeſt, their parts heating one another; and why may not great, denſe and fixed bodies, when heated beyond a certain degree, emit light ſo copiouſly, as by the emiſſion and reaction thereof, and the reflections and refractions of the rays within the pores, to grow continually hotter, till they arrive at ſuch a period of heat as is that of the ſun? Their parts may be further preſerved from fuming away, not only by their fixity, but by the vaſt weight and denſity of the atmoſphere incumbent on them, ſtrongly compreſſing them, and condenſing the vapours and exhalations ariſing from them. Thus we ſee, that warm water, in an exhauſted receiver, ſhall boil as vehemently as the hotteſt water open to the air; the weight of the incumbent atmoſphere, in this latter caſe, keeping down the vapours, and hindering the ebullition, till it has received its utmoſt degree of heat. So alſo a mixture of tin and lead, put on a red hot iron *in vacuo*, emits a fume and flame; but the ſame mixture in the open air, by reaſon of the incumbent atmoſphere, does not emit the leaſt ſenſible flame." Agreeable to this, Sir Iſaac is of opinion, that "groſs bodies may be converted into light, by the agitation of their particles; and light, again, into groſs bodies, by being fixed therein;" and he defines fire to be "a body heated ſo hot, as to emit light copiouſly; for what, (ſays he,) is a red hot iron, but fire?"

By others, fire is conſidered as a fluid *ſui generis*, an original element, which " exiſts in all bodies, and may be ſeparated or procured from them by rubbing them againſt each other, and thus putting their fire in motion. But this motion by no means generates the fire." This is the account given by Dr. Graveſande; with whom Lemery agrees, and endeavours to prove, that it is equally diffuſed through all ſpace, is preſent in all places, in the void ſpaces between bodies, as well as the inſenſible interſtices between their parts: of which opinion alſo was Dr. Boerhaave.

The firſt hypotheſis having been adopted by ſuch an eminent philoſopher as Sir Iſaac Newton, hath from thence received very conſiderable weight, and been generally received by the philoſophers in this country, it is, nevertheleſs, preſſed with almoſt inſurmountable difficulties. It can by no means be explained upon the principles of mechaniſm, becauſe it directly contradicts them. It is certain, that if one body gives motion to another that reſiſts it, the quantity of motion produced will be leſs than that of the firſt body; becauſe as much will be taken off as the reſiſtance of the firſt body was equal to. Thus, ſuppoſe a body moves in ſuch a manner as to be able to raiſe 12 pounds, if it meets with an obſtacle equivalent to ſix pounds, it will not after driving it out of the way, be able to raiſe any more than ſix pounds. The ſame rule muſt hold equally, whether we ſuppoſe the parts of matter in motion to be large or ſmall. In the above example, if we take ounces inſtead of pounds, we cannot ſuppoſe that the effect will be in the leaſt diſproportionate. If inſtead of ounces we take grains, or half grains, or the minuteſt particles, the effect muſt ſtill be the ſame.

To obviate in ſome meaſure objections of this kind, Sir Iſaac Newton ſeems to have ſuppoſed, that every particle of matter is endowed with a ſphere of attraction, and beyond that with a ſphere of repulſion. Hence, as ſoon as two particles of matter get without the ſphere of one another's attraction, they begin to repel each other very ſtrongly: and hence, ſays he, " as in algebra, where affirmative quantities ceaſe, negative ones begin; ſo in mechanics, where attraction ceaſes, there the repelling power muſt ſucceed."

Upon this principle of repulſion alone it is that the mechanical origin of heat is tenible: for if the minute particles of any body have a force impreſſed upon them, in ſuch a manner as to put them without the ſphere of each other's attraction, and then they begin to repel one another ſtrongly, it may be ſuppoſed, that putting the parts of other matter in a ſimilar ſituation, and theſe again acting upon others in a like manner, a large maſs of matter might be reſolved into its minuteſt particles, and theſe ſcattered to an immenſe diſtance by the mutual repelling power between them, and thus produce the phenomena of heat and light.

Even this will be found quite unſatisfactory, if attentively examined; for the repelling power with which theſe particles are ſuppoſed to be endowed, will have as great a tendency to drive them back upon the body from whence they came, as to drive them away from it. To help our conceptions in this matter, let us ſuppoſe, that the repulſive ſphere round each of the minute particles is an inch in diameter. Let us alſo ſuppoſe, that this repulſive force is ſufficiently great to throw the particle to the diſtance of 1000 miles, when it comes within the repulſive power of another. If, therefore, a particle is driven off from any hard ſubſtance, ſuppoſe iron, it will indeed drive another before it, which is already in the way, but will as certainly drive back upon the iron thoſe which are ſhaken off from it afterwards: for re-action is always equal to action; and if we ſuppoſe a number of ſuch particles extricated from the body, their mutual action and reaction being always equal, the motion among them muſt very ſoon ceaſe.

Upon this principle, however, the Newtonians explain the emiſſion of light from luminous bodies. "A ray of light (ſays Sir Iſaac), as ſoon as it is caſt off from the luminous body by the vibrating motion of its parts, and is got out of the ſphere of its attraction, is propelled with an immenſe velocity." Now, with all due ſubmiſſion to ſuch a great name as that of Sir Iſaac Newton, what he advances here is utterly impoſſible. All the parts of the ſun have a mutual attraction towards one another, by which they are kept together; and it is impoſſible that a particle of matter can be both attracted and repelled at the ſame moment by one body. It is indeed inconceivable, how the particles of matter can be endowed with two ſuch contrary powers, and yet remain together in one maſs: for though thoſe which lie contiguous to one another may mutually attract, yet they muſt alſo repel, and be repelled by thoſe which lie at a greater diſtance; and from ſuch a mixture of contrary forces, it does not ſeem that any body could ſolidly cohere together.

In ſupport of this hypotheſis, we may however ſuppoſe, that the vibratory motion of the parts of the ſun is ſo great, that the particles of light are thrown off by it an immenſe way beyond the orbit of Saturn. But granting this, no ſooner would they come within the ſphere of one another's repulſion, than ſome of them would be thrown back with violence towards the ſun; and, in their return, would meet with others, to which they would give a like direction; and in this they would be aſſiſted by the attractive force of the ſun himſelf, by which means the force with which the light was emitted, muſt at firſt be reſiſted, and at laſt entirely deſtroyed. But, whatever might be the caſe with the ſun, the vibratory force of whoſe parts we may ſuppoſe to be inconceivably great, it is impoſſible that upon this principle any fire could be kindled by man; for the vibratory motion induced among the particles of any body by him, could never be greater than the force originally applied; and thus muſt unavoidably decay, on account of the continual reſiſtance met with in ſetting the particles of other matter in the like motion.

To theſe objections we may alſo add, that, upon this hypotheſis, fire ought to burn beſt *in vacuo*; becauſe there the preſſure of the atmoſphere is taken off, and there ſhould be the leſs reſiſtance to the vibrations of the ſmall particles. We find, however, that fire, ſo far from burning beſt *in vacuo*, is immediately extinguiſhed; and that a free circulation of air is abſolutely neceſſary to preſerve it. Profeſſor Hamilton, indeed, of the univerſity of Dublin, endeavours to account for this, by ſaying, that air is neceſſary only to blow off the aſhes, &c. which would prevent the continuance of the motion. But if there were no other occaſion for air than this, fixed or phlogiſticated air would anſwer the ſame purpoſe; and both of theſe are found to extinguiſh fire. See Aerology.

" Air (ſays he) is not leſs neceſſary for the ſupport of fire than of animal-life; for fire will not long continue to burn without a circulation of air. Now, I ſuppoſe, this happens, not from its adding any thing to the pabulum of fire, (for fire ſeems to be otherwiſe ſufficiently provided with pabulum), but rather on this account, That the air immediately about a body on fire is heated, and made ſpecifically lighter than the air at ſome diſtance from it. This hot air, therefore, muſt aſcend, and carry with it all thoſe minute particles of different kinds which are thrown off from the burning body, and which would otherwiſe reſt upon its ſurface, and thereby clog and ſtop the ſubtile vibrations of the burning matter, in which the nature of fire partly conſiſts. If, therefore, fire be confined in a cloſe place, where there can be no circulation of air, the air about it, being ſoon ſaturated with the particles ariſing from the burning matter, will not be able to take up any more of them; and therefore the fire muſt go out, ſmothered, as it were, with ſuch particles as are no longer combuſtible. Hence it is that fire burns faſter when air is ſtrongly blown upon it; for then the aſhes are carried off as faſt as they are formed on the ſurface of the burning body; and thereby the particles that have juſt taken fire, are kept quite free from every thing that can impede or clog their vibratory motion. The air in this caſe alſo will ſpread the fire quickly through the fuel, by blowing the particles that are already kindled, among thoſe that are not; and perhaps the motion of the air in this caſe may promote the ſubtile vibrations in the burning matter by which the fire is propagated through its parts. As the air contains many ſubtile particles in the inflammable kind, it is not improbable, that theſe, mixing with the groſs burning matter, may help to preſerve and enliven the fire: but I think it moſt probable, that air ſupports fire chiefly by carrying off ſuch particles as are burned out, and would therefore obſtruct the progreſs of the fire; becauſe we find, that the ſtrong elaſtic ſteam of water driven violently out of the pipe of an æolipile, which will carry off thoſe particles, will alſo blow up and increaſe the fire as well as air driven from the bellows, although the ſteam does not contain any inflammable particles."

Here we have no reaſon given in ſupport of this hypotheſis, than that fire may be blown up by the ſteam iſſuing violently from an æolipile; but this reaſon is founded on a deception. This ſteam only blows up the fire by occaſioning a violent motion in the air through which it paſſes; and thus forcibly drives it on the fuel, at the ſame time that it enters along with it; and thus is, in ſome meaſure, ſimilar to the blowing up of a large fire by a ſteam of water, which is uſed in ſome places inſtead of bellows. Nevertheleſs, if the ſteam of the æolipile is only admitted to the fire, and the air totally excluded from it, the fire will be as effectually extinguiſhed as if the ſteam of water employed to force the air into a large furnace was itſelf directed on the fuel. Beſides, on the Doctor's hypotheſis, fixed, and many other kinds of air ought to be equally efficacious in preſerving flame, as already obſerved; which are yet found to extinguiſh it as effectually, if not more ſo than water.

Among other hypotheſes, it may not be amiſs to mention the almoſt forgotten and exploded one publiſhed by Mr. Hutchinſon, and by him pretended to be plainly revealed in the ſacred writings. According to this gentleman, the nature of fire, of light, and air, are all at bottom the ſame, being only three different modifications of the ſame fluid. When air is blown upon a fire, then the groſſer fluid is immediately reduced to its fineſt parts, and attains the utmoſt degree of poſſible fluidity, by the vehement attrition of its own particles, and thoſe of the fire already kindled, againſt one another. Being continually preſſed upon in this ſtate by the ſurrounding groſs air, it is ſent out on all ſides in ſtreams of light, which being detained among the particles of the atmoſphere, and having their motion ſtopped, become part of the air itſelf, and are again ready to reaſſume their luminous and fiery appearance on proper occaſions.

Setting aſide the pretended authority of revelation, many people have been of opinion, that this hypotheſis might be ſupported by very ſtrong arguments drawn from matter of fact. The principal are the following.

1. It is well known, that in all mixtures of different kinds of fluids, thoſe which are rareſt, and conſequently leſs acted upon by

the force of gravity than others, will raiſe to the top, and occupy the uppermoſt place in the mixture. Thus, if water and oil are mixed together, they will ſoon ſeparate themſelves, and the oil will ſwim at the top. This ſeparation happens in conſequence of their different degrees of denſity, by which the oil is leſs affected by the force of gravity than the water; not through any principle of innate levity, or any power of repulſion between this fluid and the bottom of the veſſel. In like manner, when we ſee any other two fluids mixed, and one of them aſcends, we ought not to conclude, that there is any unknown power of repulſion in that which aſcends, more than in the other. If only one of the two fluids is viſible, and that happens to be the aſcending one, we ought not therefore to ſeek for the cauſe of its aſcent in unknown and imaginary repulſions and vibrations, but rather to conclude that it is preſſed upwards by the tendency of an inviſible fluid of greater denſity downwards. In moſt caſes this is allowed by all philoſophers to hold good. The ſmoke of a fire, for inſtance, does not aſcend from it, on account of any principle of poſitive levity, or on account of a repulſive power betwixt it and the fire from which it aſcends, but from the greater tendency of the air downwards; in conſequence of which, it is driven upwards with a force equivalent to the difference of their ſpecific gravities. By analogy, (ſay they) we ought to apply this to the emiſſion of light itſelf. We have no other proof of a repulſive power between the particles of this ſubſtance, than its conſtant aſcent from a luminous body; and invent it in order to ſolve this phenomenon, when the ſame thing may be done with a much greater degree of probability, and more agreeable to the known laws of nature in other caſes, by ſuppoſing the deſcent of a denſer, though inviſible, fluid towards that body.

2. The phenomena of electricity ſhow, that there is preſent between the groſſer parts of bodies an inviſible ſubtile fluid, of exceeding great power, which on certain occaſions becomes viſible, and then diſcovers itſelf to be the real element of fire itſelf. It always appears to our eyes as a ſtream of ſubtile fire, emitting a very perceptible light. It will kindle inflammable ſubſtances; melt the moſt difficultly fuſed metals, platina itſelf not excepted; and even turn gold into glaſs, which hath never yet been done either by the fierceſt furnace or the ſtrongeſt burning mirror.

Though this hypotheſis has been laid down in its moſt diſtinct and plauſible form by Hutchinſon, or rather ſome of his followers, it appears very little if at all different from that of Boerhaave and others who maintain the impoſſibility of generating fire, and affirm it to be a fluid *ſui generis*. A direct proof of this, however, as well as of other ſuppoſitions concerning the nature of fire, is attended with great difficulties. Were we able to convert fire by itſelf into air, and convert air by itſelf into fire, the point would indeed be gained. But though we blow ever ſo much air into a fire, unleſs we continually add new fuel, it will ſoon be extinguiſhed. But this ought not to be the caſe on the Hutchinſonian hypotheſis: for one quantity of air being reduced to its utmoſt degree of fluidity, ought to reduce to the ſame ſtate every ſucceeding quantity which mixed itſelf with it; and not only would fire be kept up without any groſs fuel, but there might be ſome danger of ſetting the whole atmoſphere in a blaze at once. Thus, while one party is at a loſs to account for the uſefulneſs of air in ſupporting fire, the other is no leſs diſtreſſed with the groſs fuel, ſuch as wood, coals, &c. which ſeem to be equally neceſſary with the air itſelf for the ſupport of our fires. The Hutchinſonians, indeed, find no other uſe for the fuel but to keep off too great a quantity of air, which would oppreſs and extinguiſh a ſmall fire; but this purpoſe might be equally well anſwered by pieces of brick or ſtone; yet theſe will effectually put out a fire. The uſe of the fuel, therefore, which is continually to be added to our common fires, cannot be explained on the Hutchinſonian hypotheſis. The diſcoveries of Dr. Prieſtley, however, have put the matter beyond a doubt with reſpect to air. He hath made it apparent, that terreſtrial ſubſtances are neceſſary ingredients in the compoſition of air much purer than what we breathe, and much more capable of ſuſtaining flame; ſo that it is now an abſurdity to talk of fire and air being convertible into one another. The great proof on the Hutchinſonian ſide, and which they look upon as abſolutely unanſwerable, is the increaſe of weight in metalline calces when expoſed to the action of a ſtrong fire. This increaſe is found to be owing to air, as we have already mentioned: and though it ſhould by no means be found either fit for reſpiration, or for the purpoſes of ſupporting flame; yet it will be ſufficient for their purpoſe to prove, that the element of fire is capable of being converted into a gravitating ſubſtance; which, when diſengaged, appears in the form of a permanently elaſtic fluid, and thus becomes a certain ſpecies of air. That it really doth ſo, however, is very dubious: for it is certain that metals cannot be calcined without the free acceſs of air; and therefore it cannot certainly be known whether the air in the calx comes from the fixation of the fire, or whether it is attracted from the ſurrounding atmoſphere, eſpecially if, as ſome alledge, the calx receives no increment in weight while kept hot.

Dr. Prieſtley has made experiments on metallic calcinations; and acquaints us, that if a metal is calcined over lime-water, it doth not become turbid; becauſe, though the calcareous earth attracts the fixed air, yet the metallic calx doth it much more ſtrongly, and conſequently no precipitation can enſue. The ſame reaſon he gives why metals cannot be calcined in nitrous air; namely, that there is then no fixed air with which the metallic calx may combine, and upon which the calcination ſeemed to him to depend; nevertheleſs, the metals fumed copiouſly, though the phlogiſton was not ſeparated. Theſe experiments ſeem totally unanſwerable by the Hutchinſonians. It is well known, that fixed air is one of the component parts of our atmoſphere; and from Dr. Prieſtley's experiments, it would ſeem impoſſible to deprive a metal of its phlogiſton, but by allowing the calx to combine with fixed air; and as the fire, though conſtantly applied is not able to produce this fixed air, but muſt have the aſſiſtance of the common atmoſphere, this ſeems a demonſtration, that fire is not convertible into an elaſtic fluid of any kind. The only reply which the Hutchinſonians can give to this is, that metals will be increaſed in weight though kept over the fire in cloſe veſſels. But this may very reaſonably be ſuppoſed to proceed from the ſmall quantity of air contained in the veſſels where they are put, or from ſome inaccuracy in cloſing them, ſo that there may be ſome communication between the metals and the external air. To make theſe experiments perfect, the glaſſes ought firſt to be well exhauſted of their air, and then hermetically ſealed.

It doth not appear, therefore, that ever the element of fire hath been by human art converted into a groſſer fluid of any kind; and conſequently the only reſource left the Hutchinſonians is in arguments drawn from the ſimilarity of the electric fluid and the ſubſtance of light or fire. The late diſcoveries in electrity, indeed, have thrown ſo much light upon that ſubject, that there are now but few who deny the exiſtence of fire as a diſtinct element. It doth not, however, appear, that this element can ever be converted into any other fluid of a groſſer nature, as the Hutchinſonians affirm. The electric fluid ſeems to be equally ſubtile, and equally penetrating, with fire or light; and though it ſhould remain ever ſo long at reſt, it doth not appear that its fluidity is thereby loſt in the ſmalleſt degree. But for a full account of the experiments moſt likely to aſcertain the identity of elementary and electric fire, ſee the articles ELECTRICITY, HEAT, IGNITION, LIGHT, &c.

Wild FIRE, a kind of artificial or factitious fire, which burns even under water, and that with greater violence than out of it. It is compoſed of ſulphur, naphtha, pitch, gum, and bitumen; and is only extinguiſhable by vinegar mixed with ſand and urine, or by raw hides. Its motion or tendency is contrary to that of natural fire, and always follows the direction in which it is thrown.

Machine for Preſerving People from FIRE. This machine, conſiſts of a pole, a rope, and a baſket. The pole is of fir, or a common ſcaffold pole of any convenient length from 36 to 46 feet; the diameter at bottom, or greateſt end, about five inches: and at the top, or ſmalleſt end, about three inches. At three feet from the top is a mortiſe through the pole, and a pulley fixed to it of nearly the ſame diameter with the pole in that part. The rope is about three quarters of an inch diameter, and twice the length of the pole, with a ſpring hook at one end, to paſs through the ring in the handle of the baſket when uſed; it is put through the mortiſe over the pulley, and then drawn tight on each ſide to near the bottom of the pole, and made faſt there till wanted. The baſket ſhould be of ſtrong wicker-work, three feet and a half long, two feet and a half wide, rounded off at the corners, and four feet deep, rounding every way at the bottom. To the top of the baſket is fixed a ſtrong iron curve or handle, with an eye or ring in the middle; and to one ſide of the baſket, near the top, is fixed a ſmall cord, or guide rope, of about the length of the pole. When the pole is raiſed, and ſet againſt a houſe over the window from which any perſons are to eſcape, the manner of uſing it is ſo plain and obvious, that it needs not to be deſcribed. The moſt convenient diſtance from the houſe, for the foot of the pole to ſtand, where practicable, is about 12 or 14 feet. If two ſtrong iron ſtraps, about three feet long, rivetted to a bar croſs, and ſpreading about 14 inches at the foot, were fixed at the bottom of the pole, this would prevent its turning round or ſlipping on the pavement. And if a ſtrong iron hoop, or ferule, rivetted (or welded) to a ſemi-circular piece of iron ſpreading about 12 inches, and pointed at the ends, were fixed on at the top of the pole, it would prevent its ſliding againſt the wall. When theſe two laſt mentioned irons are fixed on, they give the pole all the ſteadineſs of a ladder; and becauſe it is not eaſy, except to perſons who have been uſed to it, to raiſe and ſet upright a pole of 40 feet or more in length, it will be convenient to have two ſmall poles, or ſpars, of about two inches diameter, fixed to the ſides of the great pole at about two or three feet above the middle of it, by iron eyes rivetted to two plates, ſo as to turn every way; the lower end of theſe ſpars to reach within a foot of the bottom of the great pole, and to have ferules and ſhort ſpikes to prevent ſliding on the pavement, when uſed occaſionally to ſupport the great pole, like a tripod. There ſhould be two ſtrong aſh trundles let through the pole, one at four feet and one at five feet from the bottom, to ſtand out about eight inches on each ſide, and to ſerve as handles, or to twiſt the rope round in lowering a very heavy weight. If a block and pulley were fixed at about the middle of the rope, above the other pulley, and the other part of the rope made to run double, it would diminiſh any weight in the baſket nearly one half, and be very uſeful in drawing any perſon up, to the aſſiſtance of thoſe in the chambers,

bers, or for removing any effects out of a chamber, which it might be dangerous to attempt by the ſtairs.

It has been proved, by repeated trials, that ſuch a pole as we have been ſpeaking of, can be raiſed from the ground, and two or three perſons taken out of the upper windows of an houſe, and ſet down ſafely in the ſtreet, in the ſpace of 35 ſeconds, or a little more than half a minute. Sick and infirm perſons, women, children, and many others, who cannot make uſe of a ladder, may be ſafely and eaſily brought down from any of the windows of an houſe on fire by this machine, and, by putting a ſhort pole through the handles of the baſket, may be removed to any diſtance without being taken out of the baſket. The pole muſt always have the rope ready fixed to it, and may be conveniently laid up upon two or three iron hooks, under any ſhade or gateway, and the baſket ſhould be kept at the watch-houſe. When the pole is laid up, the two ſpars ſhould always be turned towards the head of it. The baſket ſhould be made of peeled rods, and the pole and ſpars painted of a light ſtone-colour, to render it more viſible when uſed in the night.

Godfrey's Machines for Extinguiſhing FIRE. Of theſe the following account is given by Mr. Ambroſe Godfrey, grandſon to the inventor. "The machine to be employed, conſiſts of a ſmall portion of gunpowder cloſely confined; which, when animated by fire, acts by its elaſtic force, upon a proper medium, and not only divideth it into the minuteſt atoms, but diſperſeth it alſo in every direction, ſo as immediately to extinguiſh any fire within a certain diſtance. This medium is a liquor ſtrongly impregnated with a preparation of antiphlogiſtic principles, which, by their action upon burning materials, extinguiſh the flames, and reduce them in general to a ſtate of black coal; and by its oppoſite nature to fire, hinders the remaining ſparks, notwithſtanding the admiſſion of the air, from kindling the flames afreſh. By this means, the great point is obtained, in giving ſufficient time for totally extinguiſhing any remains of fire.

"They who preſume that water only will perform this, will find themſelves greatly miſtaken, as the draught of air will certainly rekindle the neighbouring materials, which are very fit to receive a freſh flame, the fire not being extinguiſhed by the quantity of water, but rather by the expanſion and rarefaction of its particles. There are ſeveral ſizes of theſe machines, from five to fifty pounds weight, in a portable and rather ſmall compaſs, and may generally be carried to any place where a man can go himſelf.

"But though theſe machines will prevent great fires by a timely application, they will not extinguiſh them after they have reached a frightful height, and ſeveral houſes, perhaps near a whole ſtreet, are in flames. The floors muſt be ſtanding, and acceſs to the building ſafe, otherwiſe no perſon can be ſuppoſed to approach near enough to apply them in a proper manner. Every fire has its beginning, for the moſt part, in ſome apartment; and as ſoon as diſcovered, the family, inſtead of loſing all preſence of mind, ſhould immediately apply one or more of theſe machines, which will then fully anſwer the intention. The proper time of applying them, ſuppoſes that they are ready at hand. It will be in vain to think of fetching them from any conſiderable diſtance, as it will then be too late for them to perform any important ſervice; except indeed being the probable means of ſaving ſome adjacent houſe, by extinguiſhing the flames as often as they break out, till the building firſt on fire is totally conſumed, and, by falling into ruins, leaves the other in perfect ſafety."

On the 19th of May 1761, at noon, Mr. Godfrey's experiment for extinguiſhing fire, was tried in an houſe erected for that purpoſe, near Mary-le-bone. Their royal highneſſes the duke of York, prince William Henry, prince Henry Frederic, a great number of perſons of rank and diſtinction, and many of the learned world, gave their attendance on this ſingular occaſion. The houſe, which is of brick, conſiſts of three rooms, one above another, a ſtair caſe, chimney, lath and plaſter ceilings, and a kind of wainſcotting round the rooms, of rough deal. Exactly at 12 o'clock the ground room, and that up one pair of ſtairs, were ſet on fire, by lighting the faggots and ſhavings laid in there for that purpoſe: in about 15 minutes the wainſcot of the under room was thought to be ſufficiently in flames, and three of the machines were thrown in; which by almoſt immediate and ſudden exploſions, inſtantaneouſly extinguiſhed the flames, and the very ſmoak in that apartment in a few minutes totally diſappeared. By this time, the firemen, &c. who had the care of throwing in the machines, gave an alarm that the ſtaircaſe had taken fire, and that it was neceſſary directly to go to work upon the next room; which was accordingly done, and with the ſame effect.

The experiment however, hitherto did not univerſally ſatisfy: in the laſt inſtance eſpecially it was thought to be too haſtily put in execution; and the populace, without ſide the pailing, who were ſuppoſed to amount to near 20,000, and whoſe curioſity, from the very nature of their ſituation, remained much diſſatisfied, began to grow rather riotous, and talked of a ſecond bottle-conjuror. For the ſake of the experiment, therefore, and to remove all manner of doubt, Mr. Godfrey conſented to a third experiment in the upper room, which was entirely of wood. The flames were now ſuffered to get to a conſiderable height, and even the window frames deſtroyed, before the machines were thrown in: which, however, anſwered exactly as the former had done; and, being quite in ſight of the out-ſtanders, met with univerſal approbation.

In the year 1734, the ſtates of Sweden offered a premium of 20,000 crowns for the beſt method of ſtopping the progreſs of accidental fires; when one Mr. Fuches, a German phyſician, made a preparation for that end, and the experiment was made on a houſe built on purpoſe, of dry fir, at Legard iſland. In the buildings were placed ſeveral tubs of tar and pitch, and a great quantity of chips, all which were ſet on fire; flames iſſuing through the top of the houſe, windows, &c. when he threw in one of the barrels containing the preparation, which immediately quenched the flames; a ſecond barrel entirely cleared the ſmoke away; and the whole was executed to the ſatisfaction of the ſpectators, and to the no ſmall ſatisfaction of the inventor, who was about to return home, when unexpectedly the flames broke out again, ſuppoſed to be occaſioned by a ſmall quantity of combuſtible matter being introduced and ſet on fire ſecretly by ſome malicious perſon. Upon this the wrong-headed mob fell upon Mr. Fuches, and beat him moſt unmercifully, ſo that he narrowly eſcaped with his life. He ſoon after left the country, and never could be prevailed on (though ſtrongly perſuaded by ſome of the moſt eminent citizens) to return. It is ſaid, another experiment of the ſame kind was tried in the year 1761 in Holland; but rendered abortive through the perverſeneſs of the populace. Theſe machines of Mr. Godfrey's, it is evident, would be of great uſe in extinguiſhing fires on ſhipboard; and might be conſidered as a no leſs neceſſary part of a ſhip's lading, than her ſtores or ammunition. Theſe machines, however, are found to be only ſerviceable in the beginning of a fire. When the roof had fallen in, they had no effect.

Water-Engine for Extinguiſhing FIRE. See HYDROSTATICS.

In uſing this machine we have the following improvement by Dr. Hoffman, which promiſes to be of great efficacy. As ſoon as the engine is in readineſs to work, ſtir into the water that immediately is to be diſcharged, ſeven or eight pounds of pearl-aſhes in powder, and continue to add it in this manner as occaſion requires; taking care that it be directed againſt the timber or wainſcot, &c. juſt beginning to burn; and not waſted againſt the brickwork: or, where time will admit, diſſolve any quantity of pearl-aſhes in a copper with water, and as faſt as it diſſolves, which will be in a few minutes, mix a pailful with the water in the engine, pretty often; and whatever burning wood it is played upon, will be extinguiſhed as if it was dipped in water, and will not burn afreſh in the part extinguiſhed.

FIRE *Ball*, a compoſition of meal-powder, ſulphur, ſalt-petre, &c. about the bigneſs of a hand-grenade, coated over with flax, and primed with the ſlow compoſition of a fuze. This is to be thrown into the enemy's works in the night-time, to diſcover where they are; or to fire houſes, galleries, or blinds of the beſiegers; but they are then armed with ſpikes or hooks of iron, that they may not roll off, but ſtick or hang where they are deſired to have any effect.

FIRE *Flies*, a ſpecies of flies common in Guiana, of which there are two ſpecies. The largeſt is more than an inch in length, having a very large head connected with the body by a joint of a particular ſtructure, with which at ſome times it makes a loud knock, particularly when laid on its back. The fly has two feelers or horns, two wings, and ſix legs. Under its belly is a circular patch, which, in the dark, ſhines like a candle; and on each ſide of the head near the eyes, is a prominent, globular, luminous body, in ſize about one third larger than a muſtard ſeed. Each of theſe bodies is like a living ſtar, emitting a bright, and not ſmall, light; ſince two or three of theſe animals, put into a glaſs-veſſel, afford light ſufficient to read without difficulty, if placed cloſe to the book. When the fly is dead, theſe bodies will ſtill afford conſiderable light, though it is leſs vivid than before; and if bruiſed and rubbed over the hands or face, they become luminous in the dark, like a board ſmeared over with Engliſh phoſphorous. They have a rediſh-brown or cheſnut colour; and live in rotten trees in the day, but are always abroad in the night. The other kind is not more than half as large as the former: their light proceeds from under their wings, and is ſeen only when they are elevated, like ſparks of fire appearing or diſappearing at every ſecond. Of theſe the air is full in the night, though they are never ſeen in the day. They are common not only in the ſouthern, but in the northern parts of America, during the ſummer.

FIRE *Pots*, in the military art, ſmall earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered: then the pot is covered with a piece of parchment, and two pieces of match acroſs lighted: this pot being thrown by a handle of matches where it is deſigned, it breaks and fires the powder, and burns all that is near it, and likewiſe fires the powder in the grenade, which ought to have no fuſe, to the end its operations may be the quicker.

FIRE *Ship*, an old veſſel filled with combuſtible materials, and fitted with grappling irons to hook, and ſet fire to the enemies ſhips in battle, &c. See NAVAL *Affairs*.

FIRE *Works*, or *Artificial* FIRES, are preparations made of gunpowder, ſulphur, and other inflammable and combuſtible ingredients, uſed on occaſion of public rejoicing and other ſolemnities. See PYROTECHNY.

FIRING, in the military art, denotes the diſcharge of the fire-arms; and its object is to do the utmoſt execution to the enemy. See Military Affairs.

Firing *Iron*, in farriery, a piece of copper or iron, about a foot long, one end of which is made flat, and forged like a knife; the back of it being half an inch thick, and the fore edge about the fifth or ſixth part of this. When the farrier has made his firing iron red hot in his forge, he applies the thinneſt part to the horſe's ſkin, and ſo gives the fire to ſuch places as ſtand in need of it.

FIRKIN, an Engliſh meaſure of capacity, for things liquid; containing the fourth part of the barrel. The firkin of ale contains eight gallons; and that of beer nine; two firkins of beer, make the kilderkin; two kilderkins the barrel; and two barrels the hogſhead. The firkins of ſoap and butter are on the footing of the firkins of ale; viz. a gallon per firkin leſs than that of beer.

FIRMAMENT, in the ancient aſtronomy, the eighth heaven, or ſphere; being that wherein the fixed ſtars were ſuppoſed to be placed. It is called the eighth, with reſpect to the ſeven heavens or ſpheres of the planets, which it ſurrounds. It was ſuppoſed to have two motions; a diurnal motion, given it by the primum mobile, from eaſt to weſt, about the poles of the ecliptic; and another oppoſite motion, from weſt to eaſt; which laſt it finiſhes, according to Tycho, in 25412 years; according to Ptolemy, in 36000; and according to Copernicus, in 25800; in which time the fixed ſtars return to the ſame preciſe points wherein they were at the beginning. This period is commonly called Plato's year, or the great year. In divers places of Scripture the word firmament is uſed for the middle region of the air. Many of the ancients allowed, with the moderns, that the firmament is a fluid matter; though they, who gave it the denomination of firmament, muſt have taken it for a ſolid one.

FIRMNESS, in philoſophy, denotes the conſiſtence of a body; or that ſtate, wherein its ſenſible parts cohere, or are united together, ſo that the motion of one part induces a motion to the reſt. In which ſenſe, firmneſs ſtands oppoſed to fluidity.

FIRST *Fruits*, annates or primitiæ, the profits of a benefice for the firſt year after avoidance. The firſt fruits were formerly eſtimated according to a rate or valor made under the direction of pope Innocent IV. by Walter biſhop of Norwich, in 38 Hen. III. and afterwards advanced in value by commiſſion from pope Nicholas III. A. D. 1292, 20 Edw. I. which valuation of pope Nicholas is ſtill preſerved in the exchequer; and the tenths or decimæ were the tenth part of the annual profit of each living by the ſame valuation; claimed by the holy ſee on the authority of the precept recorded in Numb. xviii. 26. Theſe papal uſurpations were firſt introduced into this kingdom by Pandulph the pope's legate, during the reigns of king John and Henry III. in the ſee of Norwich, and afterwards attempted to be made univerſal by pope Clement V. about the beginning of the fourteenth century. Theſe claims were often oppoſed by the Engliſh parliament; but they continued till the reformation in the reign of Hen. VIII. at which period it was computed, that in the compaſs of 50 years 800,000 ducats had been ſent to Rome for firſt fruits only. This revenue was annexed to the crown by 26 Hen. VIII. cap. 3. confirmed by 1 Eliz. cap. 4. and a new *valor beneficiorum* was then made, by which the clergy are at preſent rated. By theſe ſtatutes all vicarages under ten pounds a year, and all rectories under ten marks, are diſcharged from the payment of firſt fruits; and if the incumbent lives but half a year, he ſhall pay only one quarter of his firſt fruits; if one whole year, half of them; if a year and a half, three quarters; and if two years the whole. By ſtat. 27 Hen. VIII. cap. 8. no tenths are due to be paid for the firſt year; and by other ſtatutes of queen Anne, in the fifth and ſixth years of her reign, if a benefice be under fifty pounds per annum, clear yearly value, it ſhall be diſcharged of the payments of firſt fruits and tenths. Queen Anne granted her royal charter, confirmed by ſtat. 2 Ann. cap. 11. whereby the whole revenue of firſt fruits and tenths is veſted in truſtees for ever, to form a perpetual fund for the augmentation of poor livings, uſually called queen Anne's bounty. Blackſt. Comm. vol. i. p. 284, &c. Office of Firſt-fruits is kept in the temple, under the direction of a remembrancer, receiver, and comptroller, and their deputies and clerks.

FISC, Fiscus, in the civil law, the treaſury of a prince, or ſtate; or that to which all things due to the public fall. The word is derived from the Greek Φισκος, *a great baſket*, uſed when when they went to market. By the civil law, none but a ſovereign prince has a right to have a fiſc, or public treaſury. See Ærarium.

FISCAL, ſomething relating to the pecuniary intereſt of the king, the public, or a private perſon. The emperor Adrian erected the office of fiſcal advocate in the Roman empire.

FISH, in natural hiſtory, the fourth claſs of animals, including four orders, viz. *apodes*, *jugulares*, *thoracica* and *abdominales*. For the deſcription, ſee the reſpective names; for the claſſification, ſee the Syſtem of Ichthyology.

FISHERY, a place where great numbers of fiſh are caught. The principal fiſheries for ſalmon, herring, mackerel, pilchards, &c. are along the coaſts of Scotland, England, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the Eaſt and Weſt Indies.

Fishery denotes alſo the commerce of fiſh, more particularly the catching them for ſale. Were we to enter into a very minute and particular conſideration of fiſheries, as at preſent eſtabliſhed in this kingdom, this article would ſwell beyond its proper bounds; becauſe, to do juſtice to a ſubject of ſuch concernment to the Britiſh nation, requires a very ample and diſtinct diſcuſſion. We ſhall, however, obſerve, that ſince the Divine Providence hath ſo eminently ſtored the coaſts of Great Britain and Ireland with the moſt valuable fiſh; and ſince fiſheries, if ſucceſsful, become permanent nurſeries for breeding expert ſeamen; it is not only a duty we owe to the Supreme Being, not to deſpiſe the wonderful plenty he hath afforded us, by neglecting to extend this branch of commerce to the utmoſt; but it is a duty we owe to our country, for its natural ſecurity, which depends upon the ſtrength of our royal navy. No nation can have a navy, where there is not a fund of buſineſs to breed and employ ſeamen without any expence to the public; and no trade is ſo well calculated for training up theſe uſeful members of ſociety, as fiſheries.

The ſituation of the Britiſh coaſts is the moſt advantageous in the world for catching fiſh; the Scottiſh iſlands, particularly thoſe to the north and weſt, lie moſt commodious for carrying on the fiſhing trade to perfection: for no country in Europe can pretend to come up to Scotland in the abundance of the fineſt fiſh, with which its various creeks, bays, rivers, lakes, and coaſts, are repleniſhed. King Charles I. was ſo ſenſible of the great advantage to be derived from fiſheries, that he began the experiment, together with a company of merchants; but the civil wars ſoon occaſioned that project to be ſet aſide. King Charles II. made a like attempt; but his preſſing wants made him withdraw what money he had employed that way, whereupon the merchants that joined with him did the ſame. Since the union, ſeveral attempts have been made to retrieve the fiſheries, and a corporation ſettled to that effect, entitled the Royal Britiſh Fiſhery.

Cod Fishery. There are two kinds of cod fiſh; the one green or white cod, and the other dried or cured cod: though it is all the ſame fiſh, (ſee Gadus,) differently prepared; the former being ſometimes ſalted and barrelled, then taken out for uſe; and the latter, having lain ſome competent time in ſalt, dried in the ſun or ſmoak.

Green Cod Fishery. The chief fiſheries for green cod are in the bay of Canada, on the great bank of Newfoundland, and on the iſle of St. Peter, and the iſle of Sable; to which places veſſels reſort from divers parts both of Europe and America. They are from 100 to 150 tons burden, and will catch between 30,000 and 40,000 cod each. The moſt eſſential part of the fiſhery is, to have a maſter who knows how to cut up the cod, one who is ſkilled to take off the head properly, and above all a good ſalter, on which the preſerving of them, and conſequently the ſucceſs of the voyage, depends. The beſt ſeaſon is from the beginning of February to the end of April; the fiſh, which in the winter retire to the deepeſt water, coming then on the banks, and fattening extremely. What is caught from March to June keeps well; but thoſe taken in July, Auguſt, and September, when it is warm on the banks, are apt to ſpoil ſoon. Every fiſher takes but one at a time: the moſt expert will take from 350 to 400 in a day; but that is the moſt, the weight of the fiſh and the great coldneſs on the bank fatiguing very much. As ſoon as the cod are caught, the head is taken off; they are opened, gutted, and ſalted; and the ſalter ſtows them in the bottom of the hold, head to tail, in beds a fathom or two ſquare; laying layers of ſalt and fiſh alternately, but never mixing fiſh caught on different days. When they have lain thus three or four days to drain off the water, they are replaced in another part of the ſhip, and ſalted again; where they remain till the veſſel is loaded. Sometimes they are cut in thick pieces, and put in barrels for the conveniency of carriage.

Dry Cod Fishery. The principal fiſhery for this article is, from Cape Roſe to the Bay des Exports, along the coaſt of Placentia, in which compaſs there are divers commodious ports for the fiſh to be dried in. Theſe, though of the ſame kind with the freſh cod, are much ſmaller, and therefore fitter to keep, as the ſalt penetrates more eaſily into them. The fiſhery of both is much alike; only this latter is moſt expenſive, as it takes up more time, and employs more hands, and yet ſcarce half ſo much ſalt is ſpent in this as in the other.

There are four kinds of commodities drawn from cod, viz. the zounds, the tongues, the roes, and the oil extracted from the liver. The firſt is ſalted at the fiſhery, together with the fiſh, and put in barrels from 600 to 700 pound. The tongues are done in like manner, and brought in barrels from 400 to 500 pounds. The roes are alſo ſalted in barrels, and ſerve to caſt into the ſea to draw fiſh together, and particularly pilchards. The oil comes in barrels, from 400 to 520 pounds, and is uſed in dreſſing leather. In Scotland, they catch a ſmall kind of cod on the coaſts of Buchan, and all along the Murray frith on both ſides; as alſo in the frith of Forth, Clyde, &c. which is much eſteemed. They ſalt and dry them in the ſun upon rocks, and ſometimes in the chimney. They alſo cure ſkait, and other ſmaller fiſh in the ſame manner; but moſt of theſe are for home-conſumption.

Herring FISHERY. Our great ſtations for this fiſhery are off the Shetland and Weſtern iſles, and off the coaſt of Norfolk; in which the Dutch alſo ſhare. There are two ſeaſons for fiſhing herring: the firſt from June to the end of Auguſt; and the ſecond in Autumn, when the fogs become favourable for this kind of fiſhing.

Mr. Anderſon in his Hiſtory of Commerce, gives to the Scots a knowledge of great antiquity in the herring fiſhery. He ſays that the Netherlanders reſorted to theſe coaſts as early as A. D. 836, to purchaſe ſalted fiſh of the natives; but, impoſing on the ſtrangers, they learned the art, and took up the trade, in after times, of ſuch immenſe emolument to the Dutch.

Sir Walter Raleigh's obſervations on that head, extracted from the ſame author, are extremely worthy the attention of the curious, and excite reflections on the vaſt ſtrength reſulting from the wiſdom of well applied induſtry. In 1603, remarks that great man, the Dutch ſold to different nations, as many herrings as amounted to £. 1,759,000 ſterling. In the year 1615, they at once ſent out 2000 buſſes, and employed in them 37,000 fiſhermen. In the year 1618, they ſent out 3000 ſhips, with 50,000 men to take the herrings, and 9000 more ſhips to tranſport and ſell the fiſh; which by ſea and land employed 150,000 men, beſides thoſe firſt mentioned. All this wealth was got on our coaſts; while our attention was taken up in a diſtant whale-fiſhery.

Of the Scots fiſhery in the Weſtern Iſles, the following account is given by Mr. Pennant. "The fiſhing is always performed in the night, unleſs by accident. The buſſes remain at anchor, and ſend out their boats a little before ſun ſet; which continue out, in winter and ſummer, till day-light; often taking up and emptying their nets, which they do 10 or 12 times in a night, in caſe of good ſucceſs. During winter it is a moſt dangerous and fatiguing employ, by reaſon of the greatneſs and frequency of the gales, in theſe ſeas, and in ſuch gales are the moſt ſucceſsful captures: but, by the Providence of heaven, the fiſhers are ſeldom loſt; and, what is wonderful, few are viſited with illneſs. They go out well prepared, with a warm great coat, boots, and ſkin aprons, and a good proviſion of beef and ſpirits. The ſame good fortune attends the buſſes, which in the tempeſtuous ſeaſon, and in the darkeſt nights, are continually ſhifting, in theſe narrow ſeas, from harbour to harbour.

"The herrings in general are exported to the Weſt Indies, to feed the negroes; or to Ireland, for the Iriſh are not allowed to fiſh in theſe ſeas. By having a draw back of 5d. a barrel, and by repacking the fiſh in new barrels of 28 gallons, they are enabled to export them to our colonies at a cheaper rate than the Scots can do. The migration of theſe fiſh from their Northern retreat is regular; their viſits to the Weſtern iſles and coaſts, certain; but their attachment to one particular lock, extremely precarious. All have their turns; that which ſwarmed with fiſh one year, is totally deſerted the following; yet the next loch to it may be crowded with the ſhoals. Theſe changes of place give often full employ to the buſſes, who are continually ſhifting their harbour in queſt of news reſpecting theſe important wanderers.

"They commonly appear here in July; the latter end of Auguſt they go into deep water, and continue there for ſome time, without any apparent cauſe: in November, they return to the ſhallows, when a new fiſhery commences, which continues till January; at that time the herrings become full of roe, and are uſeleſs as articles of commerce. Some doubt, whether theſe herrings that appear in November are not part of a new migration; for they are as fat, and make the ſame appearance, as thoſe that compoſed the firſt.

"The ſigns of the arrival of the herrings are flocks of gulls, who catch up the fiſh while they ſkim on the ſurface; and of gannets, who plunge and bring them up from conſiderable depths. Both theſe birds are cloſely attended to by the fiſhers.

"Cod fiſh, haddocks, and dog fiſh, follow the herrings in vaſt multitudes; theſe voracious fiſh keep on the outſides of the columns, and may be a concurrent reaſon of driving the ſhoals into bays and creeks. In ſummer, they come into bays generally with the warmeſt weather, and with eaſy gales. During winter, the hard gales from north-weſt are ſuppoſed to aſſiſt in forcing them into ſhelter. Eaſt winds are very unfavourable to the fiſhery.

"In a fine day, when the fiſh appear near the ſurface, they exhibit an amazing brilliancy of colours; all the various coruſcations that dart from the diamond, ſapphire, and emerald, enrich their tract; but, during night, if they break, i. e. play on the ſurface, the ſea appears on fire, luminous as the brighteſt phoſphorus."

Herrings are cured either white, or pickled, or red.

1. Of the firſt, thoſe done by the Dutch are the moſt eſteemed, being diſtinguiſhed into four ſorts, according to their ſizes; and the beſt are thoſe that are fat, fleſhy, firm, and white, ſalted the ſame day they are taken, with good ſalt, and well barrelled. The Britiſh cured herrings are little inferior, if not equal, to the Dutch; for in ſpite of all their endeavours to conceal the ſecret, their method of curing, laſting, or caſking the herrings, has been diſcovered, and is as follows: After they have hauled in their nets, which they drag in the ſtern of their veſſels backwards and forwards in traverſing the coaſt, they throw them upon the ſhip's deck, which is cleared of every thing for that purpoſe: the crew is ſeparated into ſundry diviſions, and each diviſion has a peculiar taſk; one part opens and guts the herrings, leaving the melts and roes; another cures and ſalts them, by lining or rubbing their inſide with ſalt; the next packs them, and between each row and diviſion they ſprinkle handfuls of ſalt; laſtly, the cooper puts the finiſhing hand to all, by heading the caſks very tight, and ſtowing them in the hold.

2. Red herrings muſt lie 24 hours in the brine, in as much as they are to take all their ſalt there; and when they are taken out, they are ſpitted, that is, ſtrung by the head on little wooden ſpits, and then hung in a chimney made for that purpoſe. After which, a fire of bruſh-wood, which yields a deal of ſmoke but no flame, being made under them, they remain there till ſufficiently ſmoked and dried, and are afterwards barrelled up for keeping.

Mackerel FISHERY. The Mackarel is a ſummer fiſh of paſſage, found in large ſhoals, in divers parts of the ocean; but eſpecially on the French and Engliſh coaſts. The fiſhing is uſually in the months of April, May, and June, and even July, according to the place. They enter the Engliſh channel in April, and proceed up to the ſtreights of Dover, as the ſummer advances; ſo that by June they are on the coaſts of Cornwall, Suſſex, Normandy, Picardy, &c. where the fiſhery is moſt conſiderable. They are an excellent food, freſh; and not to be deſpiſed when well prepared, pickled, and put up in barrels: a method of preſerving them chiefly uſed in Cornwall. Naturaliſts have obſerved, that the water wherein mackerel have been boiled, often yields a light, after ſtirring it a little. See FIRE, and luminouſneſs of the SEA.

The fiſh is taken two ways; either with a line, or nets: the latter is the more conſiderable, and is uſually performed in the night time. The rules obſerved in the fiſhing for mackerel are much the ſame as thoſe already mentioned in the fiſhery of herrings.

Pearl FISHERY. See PEARL.

Salmon FISHERY. The chief ſalmon fiſheries in Europe are in England, Scotland and Ireland, in the rivers, and ſea coaſts adjoining to the river mouths. The moſt diſtinguiſhed for ſalmon in Scotland are, the river Tweed, the Clyde, the Tay, the Dee, the Don, the Spey, the Neſs, the Bewly, &c. in moſt of which it is very common, about the height of ſummer, eſpecially if the weather happens to be very hot, to catch four or five ſcore ſalmon at a draught. The chief rivers in England for ſalmon are, the Tyne, the Trent, the Severn, and the Thames. The fiſhing is performed with nets, and ſometimes with a kind of locks or weirs made on purpoſe, which in certain places have iron or wooden grates ſo diſpoſed, in an angle, that being impelled by any force in a contrary direction to the courſe of the river, they may give way and open a little at the point of contact, and immediately ſhut again, cloſing the angle. The ſalmon, therefore, coming up into the rivers, are admitted into theſe grates, which open, and ſuffer them to paſs through, but ſhut again, and prevent their return. The ſalmon is alſo caught with a ſpear, which they dart into him when they ſee him ſwimming near the ſurface of the water. It is cuſtomary likewiſe to catch them with a candle and lanthorn, or whiſp of ſtraw ſet on fire; for the fiſh naturally following the light, are ſtruck with the ſpear, or taken in a net ſpread for that purpoſe, and lifted with a ſudden jerk from the bottom.

"The capture of ſalmon in the Tweed, about the month of July, (ſays Mr. Pennant) is prodigious. In a good fiſhery, often a boat load, and ſometimes near two, are taken in a tide: ſome few years ago there were above 700 fiſh taken at one hawl, but from 50 to 100 is very frequent. The coopers in Berwick then begin to ſalt both ſalmon and gilſes in pipes and other large veſſels, and afterwards barrel them to ſend abroad, having then far more than the London markets can take off their hands.

"Moſt of the ſalmon taken before April, or to the ſetting in of the warm weather, is ſent freſh to London in baſkets: unleſs now and then the veſſel is diſappointed, by contrary winds, of ſailing immediately; in which caſe the fiſh is brought aſhore again to the coopers offices, and boiled, pickled, and kitted, and ſent to the London markets by the ſame ſhip, and freſh ſalmon put in the baſkets in lieu of the ſtale ones. At the beginning of the ſeaſon, when a ſhip is on the point of ſailing, a freſh clean ſalmon will ſell from ſix pence to a ſhilling a pound; and moſt of the time that this part of the trade is carried on, the prices are from five to ſeven ſhillings per ſtone; the value riſing and falling according to the plenty of fiſh, or the proſpect of a fair or foul wind. Some fiſh are ſent in this manner to London the latter end of September, when the weather grows cool; but then the fiſh are full of large roes, grow very thin-bellied, and are not eſteemed either palatable or wholeſome.

"The ſeaſon for fiſhing in the Tweed begins November 30th, but the fiſhermen work very little till after Chriſtmas: it ends on Michaelmas day; yet the corporation of Berwick (who are conſervators of the river) indulge the fiſhermen with a fortnight paſt that time, on account of the change of the ſtyle. There are on the river 41 conſiderable fiſheries, extending upwards, about 14 miles from the mouth, (the others above being of no great value), which are rented for near 5400l. per annum: the expence attending the ſervants wages, nets, boats, &c. amount to 5000l. more; which together make up the ſum 10,400l. Now, in conſequence, the produce muſt defray all and no leſs than 20 times that ſum of fiſh will effect it; ſo that 208,000 ſalmon muſt be caught there one year with another.

“Scotland poſſeſſes great numbers of fine fiſheries on both ſides of that kingdom. The ſalmon are cured in the ſame manner as at Berwick, and a great quantity is ſent to London in the ſpring; but after that time, the adventurers begin to barrel and export them to foreign countries: but we believe that commerce is far leſs lucrative than it was in former times, partly owing to the great increaſe of the Newfoundland fiſhery, and partly to the general relaxation of the diſcipline of abſtinence in the Romiſh church. Ireland (particularly the north) abounds with this fiſh: the moſt conſiderable fiſhery is at Cranna, on the river Ban, about a mile and an half from Coleraine.

“Mr. Pennant obſerves, that when he made the tour of that kingdom, in 1754, it was rented by a neighbouring gentleman for 620l. a year, who aſſured him, that the tenant, his predeceſſor, gave 1600l. *per annum*, and was a much greater gainer by the bargain for the reaſons before mentioned, and on account of the number of poachers who deſtroy the fiſh in the fence mouths.

“The mouth of this river faces the north; and is finely ſituated to receive the fiſh that roam along the coaſt, in ſearch of an inlet into ſome freſh water, as they do all along that end of the kingdom which oppoſes itſelf to the northern ocean. We have ſeen near Ballicaſtle, nets placed in the ſea at the foot of the promontories that jut into it, which the ſalmon ſtrike into as they are wandering cloſe to ſhore; and numbers are taken by that method. In the Ban they fiſh with nets 18 ſcore yards long, and are continually drawing night and day the whole ſeaſon, which we think laſts about four months, two ſets of 16 men each alternately relieving one another. The beſt drawing is when the tide is coming in: we were told, that at a ſingle draught there were once 840 fiſh taken. A few miles higher up the river is a wear, where a conſiderable number of fiſh that eſcape the nets are taken. We were lately informed, that, in the year 1780, about 320 tons were taken in the Cranna fiſhery.”

Curing Salmon. When the ſalmon are taken, they open them along the back, take out the guts and gills, and cut out the greateſt part of the bones, endeavouring to make the inſide as ſmooth as poſſible: they then ſalt the fiſh in large tubs for the purpoſe, where they lie a conſiderable time ſoaking in brine; and about October, they are packed cloſe up in barrels, and ſent to London, or exported up the Mediterranean. They have alſo in Scotland, a great deal of ſalmon ſalted in the common way, which after ſoaking in brine a competent time, is well preſſed, and then dried in ſmoke: this is called kipper, and is chiefly made for home conſumption; and, if properly cured and prepared, is reckoned very delicious.

Sturgeon FISHERY. The greateſt ſturgeon fiſhery is in the mouth of the Volga, on the Caſpian ſea; where the Muſcovites employ a great number of hands, and catch them in a kind of incloſure formed by huge ſtakes repreſenting the letter Z repeated ſeveral times. Theſe fiſheries are open on the ſide next the ſea, and cloſe on the other; by which means the fiſh aſcending in its ſeaſon up the river, is embarraſſed in theſe narrow angular retreats, and ſo is eaſily killed with a harping iron. Sturgeons, when freſh, eat deliciouſly; and in order to make them keep, they are ſalted or pickled in large pieces, and put up in cags from 30 to 50 pounds. But the great object of this fiſhery is the roe, of which the Muſcovites are extremely fond, and of which is made the cavear, or kavia, ſo much eſteemed by the Italians. See CAVEAR.

Whale FISHERY. Whales are chiefly caught in the north ſeas: the largeſt ſort are found about Greenland, or Spitzbergen. At the firſt diſcovery of this country, and at the firſt beginning of this fiſhery, they took nothing but the pure oil and the whalebone, and all the buſineſs was executed in the country; by which means a ſhip could bring home the product of many more whales than ſhe can according to the preſent method of conducting this trade. The fiſhery alſo was then ſo plentiful, that they were obliged ſometimes to ſend other ſhips to fetch off the oil they had made, the quantity being more than the fiſhing ſhips could bring away. But time and change of circumſtances have ſhifted the ſituation of this trade; the ſhips coming in ſuch numbers from Holland, Denmark, Hamburgh, and other northern countries, all intruders upon the Engliſh, who were the firſt diſcoverers of Greenland.

The whale fiſhery begins in May, and continues all June and July; but whether the ſhips have good or bad ſucceſs, they muſt come away, and get clear of the ice, by the end of Auguſt; ſo that in the month of September at fartheſt, they may be expected home; but a ſhip that meets with a fortunate and early fiſhery in May, may return in June or July.

The manner of taking whales at preſent is as follows: Every ſhip is provided with ſix boats, to each of which belong ſix men for rowing the boat, and an harpooneer, whoſe buſineſs is to ſtrike the whale with his harpoon. Two of theſe boats are kept conſtantly on the watch at ſome diſtance from the ſhip, faſtened to pieces of ice, and are relieved by others every four hours. As ſoon as a whale is perceived, both the boats ſet out in purſuit of it, and if either of them can come up before the whale finally deſcends, which is known by his throwing up his tail, the harpooneer diſcharges his harpoon at him. There is no difficulty in chooſing the place where the whale is to be ſtruck, as ſome have aſſerted; for theſe creatures only come up to the ſurface in order to ſpout up the water, or blow, as the fiſhermen term it, and therefore always keep the ſoft and vulnerable part of their bodies above water. A late improvement was made in the method of diſcharging the harpoon; namely, by ſhooting it out of a kind of ſwivel or muſquetoon: but it doth not appear that, ſince this improvement was made, the whale-fiſhing ſhips have had better ſucceſs than before. As ſoon as the whale is ſtruck, the men ſet up one of their oars in the middle of the boat as a ſignal to thoſe in the ſhip. On perceiving this, the watchmen alarms all the reſt with the cry of *fall! fall!* upon which all the other boats are immediately ſent out to the aſſiſtance of the firſt.

The whale finding himſelf wounded, runs off with prodigious violence. Sometimes he deſcends perpendicularly; at others goes off horizontally, at a ſmall depth below the ſurface. The rope which is faſtened to the harpoon is about 200 fathoms long, and properly coiled up, that it may freely be given out as there is a demand for it. At firſt, the velocity with which this line runs over the ſide of the boat is ſo great, that it is wetted to prevent its taking fire; but in a ſhort time the ſtrength of the whale begins to fail, and the fiſhermen, inſtead of letting out more rope, ſtrive as much as poſſible to pull back what is given out already, though they always find themſelves neceſſitated to yield at laſt to the efforts of the animal, to prevent his ſinking their boat. If he runs out the 200 fathoms of line contained in one boat, that belonging to another is immediately faſtened to the end of the firſt, and ſo on; and there have been inſtances, where all the rope belonging to the ſix boats has been neceſſary, though half that quantity is ſeldom required.

The whale cannot ſtay long below water, but again comes up to blow; and being now much fatigued and wounded, ſtays longer above water than uſual. This gives another boat time to come up with him, and he is again ſtruck with an harpoon. He again deſcends, but with leſs force than before; and when he comes up again, is generally incapable of deſcending, but ſuffers himſelf to be wounded and killed with long lances which the men are provided with for the purpoſe. He is known to be near death when he ſpouts up the water deeply tinged with blood. A conſiderable trade is alſo carried on to the South-Seas, as the whales in that quarter, though inferior in ſize to thoſe of the northern climes, are much more valuable, in producing the ſpermaceti, a very profitable branch of commerce.

Beſides theſe fiſheries, there are ſeveral others both on the coaſts of Great Britain and in the North Seas, which, although not much the ſubject of merchandize, nevertheleſs employ great numbers of ſhips and men; as, 1. The oyſter-fiſhing at Colcheſter, Feverſham, Milton, the iſle of Wight, in the Swales of the Medway, and in all the creeks between Southampton and Chicheſter, from whence they are carried to be fed in pits about Wevenhoe and other places. (See OSTREA.) 2. The lobſter-fiſhing all along the Britiſh Channel, the Frith of Edinburgh, on the coaſt of Northumberland, and on the coaſt of Norway, from whence great quantities are brought to London. 3. And laſtly, The fiſhing of the pot-fiſh, fin-fiſh, ſea-unicorn, ſea-horſe, and the ſeal, or dog-fiſh; all which are found in the ſame ſeas with the whales, and yield blubber in a certain degree; beſides, the horn of the unicorn is as eſtimable as ivory, and the ſkins of the ſeals are particularly uſeful to trunk-makers.

FISHING, in general, the art of catching fiſh, whether by means of nets, of ſpears, or of the line and hook.

FISHING in the great, performed by the net, ſpear, or harpoon, has been explained in the preceding article. That performed by the rod, line and hook, is uſually termed angling: and for the particular manner of angling for the different kinds of fiſh, ſee their reſpective names.

Right of FISHING, and property of fiſh. It has been held, that where the lord of the manor hath the ſoil on both ſides of the river, it is a good evidence that he hath a right of fiſhing; and it puts the proof upon him who claims *liberam piſcariam:* but where a river ebbs and flows, and is an arm of the ſea, there it is common to all, and he who claims a privilege to himſelf muſt prove it; for if the treſpaſs is brought for fiſhing there, the defendant may juſtify, that the place where is *brachium maris, in quo unuſquiſque ſubditus domini regis habet et habere debet liberam piſcariam.* In the Severn the ſoil belongs to the owners of the land on each ſide; and the ſoil of the river Thames is in the king, but the fiſhing is common to all. He who is owner of the ſoil of a private river, hath *ſeparalis piſcaria*; and he that hath *libera piſcaria*, hath a property in the fiſh, and may bring a poſſeſſory action for them; but *communis piſcaria* is like the caſe of all other commons. One that has a cloſe pond in which there are fiſh, may call them *piſces ſuos*, in an indictment, &c. but he cannot call them *bona & catalla*, if they be not in trunks. There needs no privilege to make a fiſh-pond, as there doth in the caſe of a warren. See FRANCHISE. Jacob's Law Dictionary.

FISSURES, in the hiſtory of the earth, certain interruptions that horizontally or parallely divide the ſeveral ſtrata of which the body of our terreſtrial globe is compoſed.

FISTULA, in ſurgery, a deep, narrow, and callous ulcer, generally ariſing from abſceſſes. It differs from a ſinus, in its being callous, the latter not. See **Surgery**.

Fistula, in farriery. See Syſtem of **Farriery**. Sect XII.

FISTULARIA, or **Tobacco-pipe Fish**; a genus of fiſhes, belonging to the order of abdominales. Of this genus Linnæus enumerates only two ſpecies.

FIT, in medicine, an acceſs or paroxyſm. See **Paroxysm**.

FITCHEE, or **Fichee**, in heraldry, is when the lower part of any croſs is ſharpened into a point fit to fix into the ground. Thus, he bears azure, a croſs potent fitchee.

FITZ, a French term, literally denoting ſon, ſometimes given by way of addition to the natural ſons of the kings of England; as James Fitz-Roy, duke of Grafton, &c.

FIXATION, in chymiſtry, the rendering any volatile ſubſtance fixed, ſo as not to fly off upon being expoſed to a great heat; hence,

FIXED *Bodies*, are thoſe which bear a conſiderable degree of heat without evaporating, or loſing any of their weight. Among the moſt fixed bodies are diamonds, gold, &c. See **Diamond**, **Gold**, &c.

Fixed *Bodies*, in the general, are thoſe which neither the fire nor any corroſive has ſuch effect on, as to reduce or reſolve into their component elements; i. e. abſolutely to deſtroy them.

Fixed *Stars* are ſuch as conſtantly retain the ſame poſition and diſtance with reſpect to each other. By which they are contradiſtinguiſhed from erratic or wandering ſtars, which are continually ſhifting their ſituation and diſtance. The fixed ſtars are what we properly and abſolutely call ſtars; the reſt have their peculiar denomination of planet and comet.

FIXITY, or **Fixedness**, in philoſophy, the quality of a body which denominates and renders it fixed; or a property which enables it to endure the fire and other violent agents.

Fixity, or **Fixedness**, in chymiſtry, is, in a peculiar manner, uſed for the affection oppoſite to volatility; i. e. the property whereby bodies bear the action of the fire, without being diſſipated in fumes.

FLACCIDITY, in medicine, &c. a diſorder of the fibres or ſolid parts of the body, oppoſed to rigidity. The too great flaccidity of the parts is cured by cardiacs, exerciſe, friction, a dry warm air, proper food, &c.

FLAG, a general name, including colours, ſtandards, ancients, banners, enſigns, &c. which authors frequently confound with each other.

Flag is more particularly uſed in ſea language, for the colours, ancients, ſtandards, &c. borne on the top of the maſts of veſſels, to notify the quality of the perſon who commands the ſhip, of what nation it is, and whether it be equipped for war or trade. For a particular deſcription of the flags of this, and other nations, ſee **Naval Affairs**.

Flags, in the military art, are ſmall banners of diſtinction ſtuck in the baggage-waggons of the army, to diſtinguiſh the baggage of one brigade from another, and of battalion from another, that they may be marſhalled by the waggon-maſter-general according to the rank of their brigades, to avoid the confuſion that otherwiſe might ariſe.

Flag *Officers*, thoſe who command the ſeveral ſquadrons of a fleet; as admirals, vice-admirals, and rear-admirals. The flag-officers in our ſea-pay, are the admiral, vice-admiral, and rear-admiral, of the white, red, and blue.

Flag *Ship*, a ſhip commanded by a general or flag-officer, who has a right to carry a flag, in contradiſtinction to the ſecondary veſſels under the command thereof.

Flag *Staves*, are the ſtaves ſet on the heads of the top-gallant maſts, ſerving to let fly and unfurl the flag.

FLAGELLANTES, a ſect of wild fanatics who chaſtiſed and diſciplined themſelves with whips in public. The ſect of the flagellantes had its riſe in Italy in the year 1260; its author was one Rainier, a hermit; and it was propagated from hence through almoſt all the countries of Europe. It was in all probability no more than the effect of an indiſcreet zeal. A great number of perſons of all ages and ſexes made proceſſions, walking two by two with their ſhoulders bare, which they whipped till the blood ran down, in order to obtain mercy from God, and appeaſe his indignation again the wickedneſs of the age. They were then called the devout; and having eſtabliſhed a ſuperior, he was called the general of the devotion. Though the primitive flagellantes were exemplary in point of morals, yet they were joined by a turbulent rabble, who were infected with the moſt ridiculous and impious opinions; ſo that the emperors and pontiffs thought proper to put an end to this religious phrenzy, by declaring all devout whipping interest. contrary to the Divine Law, and prejudicial to man's eternal

FLAGELLATION, whipping, a voluntary diſcipline, or penance, frequently practiſed by the ancient penitents. The parliament of Paris prohibited all public flagellations by an arret of 1601.

Flagellation is a term more peculiarly appropriated to the ſufferings of Jeſus Chriſt, when whipped and ſcourged by the Jews; from the Latin, *flagellum*, *a ſcourge* or *whip*.

FLAGEOLET, or **Flajolet**, a kind of a little flute; or a muſical inſtrument of the flute kind, uſed chiefly by ſhepherds and country people. It is uſually made of box, or ſome other hard wood, ſometimes of ivory. It has ſix holes or ſtops beſides that at bottom, the mouth-piece, and that behind the neck. The ambit of the flageolet, according to the ſcale exhibited by Merſennus, is two octaves from *a ſol re ut* upwards.

FLAIL, an inſtrument for threſhing corn. It conſiſts of the following parts. 1. The hand-ſtaff, or piece held in the threſher's hand. 2. The ſwiple, or that part which ſtrikes out the corn. 3. The caplins, or ſtrong double leathers, made faſt to the tops of the hand-ſtaff and ſwiple. 4. The middle-band, being the leather thong, or fiſh-ſkin, that ties the caplins together.

FLAKE *White*, in painting, is lead corroded by means of the preſſing of grapes, or a ceruſe prepared by the acid of grapes. It is brought here from Italy, and far ſurpaſſes, both with regard to the purity of its whiteneſs and the certainty of its ſtanding, all the ceruſe or white lead made with us in common. It is uſed in oil and varniſh painting for all purpoſes, where a very clean white is required. The white flake ſhould be procured in lumps as it is brought over, and levigated by thoſe who uſe it, becauſe that which the colourmen ſell in a prepared ſtate is levigated and mixed up with ſtarch, and often with white lead, and worſe ſophiſtications.

FLAME, is a general name for every kind of luminous vapour, provided the light it emits hath any conſiderable degree of intenſity. The name flame, however, is moſt generally applied to ſuch as are of a conical figure, like thoſe ariſing from our common fires; without this, they are commonly called luminous vapours, or ſimply lights. According to Sir Iſaac Newton, flame is only red-hot ſmoke, or the vapour of any ſubſtance raiſed from it by fire and heated to ſuch a degree as to emit light copiouſly.

But Dr. Prieſtley has properly obſerved, that the ſmoke of common fuel conſiſts of two very different things: that which riſes firſt is mere water, loaded with ſome of the groſſer parts of the fuel, and is hardly more capable of becoming red-hot than water itſelf; but the other kind of ſmoke, which alone is capable of ignition, is properly inflammable air, which is alſo loaded with other heterogeneous matter, ſo as to appear like a very denſe ſmoke. A lighted candle ſoon ſhews them to be eſſentially different; for one of them inſtantly takes fire, whereas the other extinguiſhes a candle. Prieſtley on Air, vol. i. p. 207.

It is certain, that bodies are capable of emitting flame only in proportion to the quantity of vapour that riſes from them. Thus wood, coals, &c. which emit a great quantity of vapour, flame violently; while lead, tin, &c. which emit but a ſmall fume, can ſcarce be perceived to flame at all. Some vapours ſeem to be in their own nature uninflammable, and capable of extinguiſhing flame, as thoſe of water, the mineral acids, ſal-ammoniac, arſenic, &c. while others take fire on the ſlighteſt approach of a flaming ſubſtance, ſuch as ether, ſpirit of wine, &c. Theſe laſt mentioned ſubſtances alſo exhibit a remarkable phenomenon; namely, that they cannot be made to flame without the approach of ſome ſubſtance actually in flames beforehand. Thus, ſpirit of wine, poured on a red-hot iron, though inſtantly diſſipated in vapour, will not flame; but if a burning candle touches its ſurface, the whole is ſet in a flame at once. The caſe is otherwiſe with oils, eſpecially thoſe of the groſſer kind; for their vapours will readily be changed into flame by the mere increaſe of heat, without the approach of any flaming ſubſtance.

There is however, no kind of vapour, perhaps, that is incapable of being converted into flame, provided it is expoſed to a ſufficient degree of heat. Thus the vapour of water, made to paſs through burning coals, produces an exceedingly ſtrong and bright flame. It is remarkable, that this kind of vapour ſeems to be more powerful than almoſt any other in abſorbing heat, and detaining it in a latent ſtate. Dr. Black hath ſhewn, that when any quantity of aqueous vapour is condenſed, more heat will be ſeparated from it than would have been ſufficient to heat an equal bulk of iron red-hot. It is moſt probably to this property which all vapours have of abſorbing heat, and detaining it in a latent ſtate, that we are to attribute the phenomena of flame, and alſo the exceeding great elaſticity of ſteam. It is certain, that vapours, of water at leaſt, have a much greater power of abſorbing and retaining heat, than the water from which they are raiſed. In open veſſels, water cannot be heated more than 212 degrees of Fahrenheit's thermometer; but in Papin's digeſter, where the vapour is forcibly confined, it has been heated to 400 of the ſame degrees; and, no doubt, might have been heated a great deal more, had the veſſels been ſtrong enough to bear the expanſile force of the ſteam. On opening the veſſels, however, the exceſs of heat was found to have reſided entirely in the vapour; for the water in the veſſel very ſoon ſunk down to 212°, while the ſteam iſſued forth with great violence. From theſe experiments it appears, that the ſteam of water, after it has abſorbed as much heat in a latent ſtate as it can contain, continues to abſorb, or detain among its particles, an unlimited quantity of ſenſible heat; and if the ſteam could be confined till this quantity became great enough to be viſible by its emiſſion of light, there cannot be the leaſt doubt that the vapour would then be converted into flame.

We find that when gun-powder takes fire, it goes off in a flaming ſmoke. The manner we conceive to be this: the charcoal and ſulphur eaſily take fire, and ſet fire to the nitre; by which the ſpirit of the nitre being rarefied into vapour, ruſhes out like the vapour of water out of an æolipile. Then the acid ſpirit of the ſulphur entering violently into the fixed body of the nitre ſets looſe the ſpirit of the nitre, and excites a greater fermentation, whereby the heat is increaſed, and the fixed body of the nitre rarefied into fume, and thus is a vehement exploſion effected. The flame of gun-powder ariſes from a violent action, whereby the mixt being quickly and vehemently heated, is rarefied and converted into fume and vapour: which vapour, by the violence of the action becoming ſo hot as to ſhine, appears in the form of flame. Newt. Optics, p. 318. See Air, Fire, Heat, and Phologiston. Flames are of different colours, according to the ſubſtances from which they are produced. Thus, the flame of ſulphur and ſpirit of wine is blue; the flame of nitre and zinc, of a bright white; that of copper, of a greeniſh blue, &c. Theſe varieties afford an opportunity of making a number of agreeable repreſentations in fire work, which could not be done if the flame produced from every different ſubſtance was of the ſame colour. See Pyrotechnics. We have ſeveral inſtances of actual flame being produced by the mixture of two cold liquors. Dr. Slare gives us a liſt of the oils which burſt into flame upon mixing them with compound ſpirit of nitre; ſuch are thoſe of caraways, cloves, ſaſſafras, guaiacum, box, camphire, pepper, hartſhorn, blood, &c. Philoſoph. Tranſact. N° 213.

FLAMEN, among the ancient Romans, was a prieſt or miniſter of ſacrifice. There were as many kinds of flamens at Rome as there were gods who had prieſts and ſacrifices offered them.

FLANCONADE, in fencing, is the action of dropping the point of your ſword under your adverſary's hilt, in ſeizing with force the feeble of his blade; which, binding without quitting it, form the parade in octave, and then throw in your thruſt. See Syſtem of Fencing, deſcription of Fig. IV. Plate I.

FLANEL, or Flannel, a kind of ſlight, looſe, woollen ſtuff, not quilted, but very warm, compoſed of a woof and warp, and wove on a loom with two treddles, after the manner of bays.

FLANK, or Flanc, is applied to the ſides of a horſe's buttocks, &c. In a ſtrict ſenſe, the flanks of a horſe are the extremes of the belly, where the ribs are wanting, and are below the loins.

Flank, in fortification, is a line drawn from the extremity of the face towards the inſide of the work. Or, flank is that part of a baſtion which reaches from the curtain to the face, and defends the oppoſite face, the flank and the curtain.

FLANKING, in general, is the act of diſcovering and firing upon the ſide of a place, body, battalion, &c. To flank a place, is to diſpoſe a place or other work in ſuch a manner as that there ſhall be no part of the place but what may be played on, both in front and rear. Any fortification that has no defence but juſt right forwards is faulty; and to render it complete, one part ought to be made to flank the other. Hence the curtain is always the ſtrongeſt part of any place, becauſe it is flanked at each end. Battalions alſo are ſaid to be flanked by the wings of the cavalry. A houſe is ſometimes ſaid to be flanked with two pavilions, or two galleries, meaning it has a gallery, &c. on each ſide.

FLAT *Bottomed Boats* are ſuch as are made to ſwim in ſhallow water, and to carry a great number of troops, artillery, ammunition, &c.

Flats, in muſic, a kind of additional or half-notes contrived together with ſharps, to remedy the defects of muſical inſtruments.

FLATULENCY, a word uſed by medical writers to expreſs a diſtempered ſtate of the body in which there is an uncommon and unnatural generation of flatuſes or halituous and elaſtic matter of the nature of air, ariſing from the humidity of the abdomen, and attended with ſeveral very bad ſymptoms.

FLATULENT, ſomething that has a relation to flatuſes, or blaſts of wind. Peas, and moſt kind of pulſe, onions, &c. are flatulent foods.

FLAX, the Engliſh name of the genus Linum, for a deſcription of which and its ſpecies, ſee Linum. For the cultivation of flax, ſee Syſtem of Agriculture, Sect. XVIII. For the dreſſing of flax, ſee the following.

Flax *Dreſſing*. For many ages it was the practice to ſeparate the boon or core from the flax, which is the bark of the plant, by the following ſimple hand methods. Firſt, for breaking the boon, the ſtalks in ſmall parcels were beat with a mallet. This method of breaking and ſcutching the flax being ſlow and very laborious, a water mill is ſometimes uſed; which, with ſome late improvements, makes great diſpatch, and in ſkilful and careful hands gives ſatisfaction.

The ſcutching is next carried on by the mill in the following manner: Four arms, ſomething like the hand-ſcutchers before deſcribed, project from a perpendicular axle; a box around the axle incloſes theſe projecting ſcutchers; and this box is divided among the workmen, each having ſufficient room to ſtand and handle his flax, which, through ſlits in the upper part and ſides of the box, they hold in to the ſtroke of the ſcutchers: which moving round horizontally, ſtrike the flax a-croſs or at right angles, and ſo threſh out or clear it of the boon.

The breaking of the flax by rollers is ſcarcely ſubject to any objection, but that it is dangerous to workmen not ſufficiently on their guard, who ſometimes allow the rollers to take hold of their fingers, and thereby their whole arm is inſtantly drawn in; thus many have loſt their arms. To avoid this danger, a break upon the general principles of the hand-break before deſcribed, has been lately adapted to water-machinery, and uſed in place of rollers. The horizontal ſtroke of the ſcutchers was long thought too ſevere, and waſteful of the flax; but very careful experiments have diſcovered that the waſte complained of muſt be charged to the unſkilfulneſs or negligence of the workmen, as in good hands the mill carries away nothing but what, if not ſo ſcutched off, muſt be taken off in the heckling with more loſs both of time and flax. But to obviate this objection of the violence of the horizontal ſcutchers, an imitation of hand-ſcutching has lately been applied to water. The ſcutchers then project from an horizontal axle, and move like the arms of a check-reel, ſtriking the flax neither acroſs nor perpendicularly down, but ſloping in upon the parcel exactly as the flax is ſtruck by the hand-ſcutcher. This ſloping ſtroke is got by raiſing the ſcutching-ſtock ſome inches higher than the centre of the axle; and by raiſing or lowering the ſtock, over which the flax is held, or ſcrewing it nearer to or farther from the ſcutchers, the workmen can temper or humour the ſtroke almoſt as he pleaſes.

A lint mill with horizontal ſcutchers upon a perpendicular axle requires a houſe of two ſtories, the rollers or break being placed in the ground ſtory, and the ſcutchers in the loft above; but a mill with vertical ſcutchers on an horizontal axle, requires but one ground ſtory for all the machinery. Another method of breaking and ſcutching flax, more expeditious than the old hand methods and more gentle than water-mills has alſo been lately invented. It is much like the break and ſcutcher giving the ſloping ſtroke laſt deſcribed, moved by the foot. The treddle is remarkably long, and the ſcutchers are fixed upon the rim of a fly-wheel. The foot-break is alſo aſſiſted in its motion by a fly. Theſe foot machines are very uſeful where there are no water-mills, but they are far inferior to the mills in point of expedition.

The next operation that flax undergoes after ſcutching is heckling. The heckle is firmly fixed to a bench before the workman, who ſtrikes the flax upon the teeth of the heckle, and draws it through the teeth. To perſons unacquainted with that kind of work this may ſeem a very ſimple operation; but, in fact, it requires as much practiſe to acquire the ſlight of heckling well, and without waſting the flax, as any other operation in the whole manufacture of linen. They uſe coarſer and wider teethed heckles, or finer, according to the quality of the flax, generally putting the flax through two heckles, a coarſer one firſt, and next a fine one.

Flax for cambric and fine lawn, thread, and lace, is dreſſed in a manner ſomewhat different. It is not ſkutched ſo thoroughly as common flax; which from the ſkutch proceeds to the heckle, and from that to the ſpinner: whereas, this fine flax, after a rough ſkutching, is ſcraped and cleanſed with a blunt knife upon the workman's knee covered with his leather apron; from the knife it proceeds to the ſpinner, who, with a bruſh made for the purpoſe, ſtraights and dreſſes each parcel juſt before ſhe begins to ſpin it.

Flax *made to reſemble Cotton*. In the Swediſh tranſactions for the year 1747, a method is given of preparing flax in ſuch a manner as to reſemble cotton in whiteneſs and ſoftneſs, as well as in coherence. For this purpoſe, a little ſea-water is to be put into an iron pot or an untinned copper-kettle, and a mixture of equal parts of birch-aſhes and quicklime ſtrewed upon it: a ſmall bundle of flax is to be opened and ſpread upon the ſurface, and covered with more of the mixture, and the ſtratification continued till the veſſel is ſufficiently filled. The whole is then to be boiled with ſea-water for ten hours, freſh quantities of water being occaſionally ſupplied in proportion to the evaporation, that the matter may never become dry. The boiled flax is to be immediately waſhed in the ſea by a little at a time, in a baſket, with a ſmooth ſtick: When grown cold enough to be borne by the hands, it muſt be well rubbed, waſhed with ſoap, laid to bleach, and turned and watered every day. Repetitions of the waſhing with ſoap expedite the bleaching; after which the flax is to be beat in again well waſhed; when dry, it is to be worked and carded in the ſame manner as common cotton, and preſſed betwixt two boards for 48 hours. It is now fully prepared and fit for uſe. It loſes in this proceſs near one half its weight, which is abundantly compenſated by the improvement made in its quality.

Flax *Plant*, is a name which we may give to a plant that ſerves the inhabitants of New Zealand inſtead of hemp and flax. Of this plant there are two ſorts; the leaves of both reſemble thoſe of flags, but the flowers are ſmaller, and their cluſters more numerous; in one kind they are yellow, and in the other a deep red. Of the leaves of theſe plants, with very little preparation, they make all their common apparel, and alſo their ſtrings, lines, and cordage, for every purpoſe, which are ſo much ſtronger than any thing we can make with hemp, that they will not bear a compariſon. From the ſame plant, by another preparation, they draw long ſlender fibres, which ſhine like ſilk, and are as white as ſnow: of theſe which are very ſtrong, they make their fineſt cloaths; and of the leaves, without any other preparation than ſplitting them into proper breadths, and tying the ſtrips together, they make their fiſhing nets, ſome of which are of an enormous ſize. Hawkeſworth's Voyag. vol. iii. p. 39.

The ſeeds of this valuable plant have been brought over into England; but, upon trial, appeared to have loſt their vegetating power. The filamentous parts of different vegetables have been employed in different countries for the ſame mechanic uſes as hemp and flax among us. Putrefaction, and in ſome degree alcaline lixivia, deſtroy the pulpy or fleſhy matter, and leave the tough filaments entire. By curiouſly putrefying the leaf of a plant in water, we obtain the fine flexible fibres.

Earth FLAX. See AMIANTHUS.

FLEA, in entomology, the Engliſh name of the genus pulex belonging to the order of aptera; for a particular deſcription of which, ſee PULEX.

FLEAM, in ſurgery and farriery, an inſtrument for letting blood of a man or horſe. A caſe of fleams, as it is called by farriers, comprehends ſix ſorts of inſtruments; two hooked ones, called drawers, and uſed for cleaning wounds; a pen knife; a ſharp pointed lancet, for making inciſions; and two fleams, one ſharp and the other broad pointed. Theſe laſt are ſomewhat like the point of a lancet, fixed in a flat handle, and no longer than is juſt neceſſary to open the vein.

FLEECE, the covering of wool ſhorn off the bodies of ſheep.

The Golden FLEECE, is famous among the ancient writers. It was this that the Argonauts, under the command of Jaſon, went in purſuit of to Colchis, a province of Aſia, now called Mingrelia. The miſtery of the golden fleece is variouſly explained; either of the profit of the wool trade to Colchis; or of the gold that they commonly gather there, with fleeces, in the rivers. Arbuth. Diſſ. p. 224. See ARGONAUTS.

FLEET, a number of veſſels, going in company, whether on a deſign of war, or commerce. In times of peace, merchants ſhips go in fleets, for their mutual aid and aſſiſtance: in times of war, beſides this ſecurity, they likewiſe procure convoys of men of war; either to eſcort them to the places whither they are bound, or only a part of the way, to a certain point or latitude, beyond which they are judged out of danger of privateers, &c.

FLEET is alſo a priſon in London, thus called from the river Fleet, on the border whereof it once ſtood. To this priſon perſons are uſually committed for contempt of the king and his laws; or upon abſolute command of the king, or ſome of his courts, particularly that of chancery; and laſtly, for debt.

FLEMISH, or the Flemiſh tongue, is that which we otherwiſe call low Dutch, to diſtinguiſh it from the German, whereof it is a corruption, and a kind of dialect. The Flemiſh is the language uſed throughout the provinces of the Netherlands. It differs conſiderably from the Walloon, which is a corrupt French.

FLESH, *Caro*, in anatomy, a fibrous part of an animal body, ſoft and bloody; being that whereof moſt of the other parts are compoſed, and whereby they are connected together. Fleſh is properly underſtood of ſuch parts of the body where the blood-veſſels are ſo ſmall, as only to retain blood enough to preſerve their colour red. The ancients accounted five different kinds of fleſh; the firſt muſcular, fibrous, or fiſtular; as the ſubſtance of the heart, and other muſcles; the ſecond parenchymous, as that of the lungs, liver, and ſpleen; the third viſcerous, as the fleſh of the ſtomach and inteſtines; the fourth glandulous, as that of the breaſts, pancreas, tonſils, &c. and the fifth ſpurious, as that of the gums, glans of the penis, the lips, &c. The moderns admit only of one kind of fleſh: viz. the muſcular, conſiſting of little tubes and veſſels, with blood therein; ſo that fleſhy and muſcular parts of the body with them are the ſame thing. Sometimes, however, they apply the terms to the glands, which they call, by way of diſtinction, glandulous fleſh. As to the parenchymas, they are now found to be quite other things than the ancients imagined. The lungs are only an aſſemblage of membranous veſicles, inflated with air; the liver a collection of glands, wherein the bile is ſeparated; the ſpleen, a heap of veſicles, full of blood; and the kidneys, like the liver, a maſs of glands for ſeparating of the urine.

FLESH is alſo uſed, in theology, in ſpeaking of the myſteries of the incarnation and euchariſt. The word was made fleſh, *Verbum caro factum eſt*. The Romaniſts hold, that the bread in the ſacrament of the ſupper is turned into the real fleſh of Jeſus Chriſt. See TRANSUBSTANTIATION.

FLESH is ſometimes alſo uſed by botaniſts for the ſoft pulpy ſubſtance of any fruit, incloſed between the outer rind or ſkin, and the ſeeds, or ſtone; or for that part of a root, fruit, &c. fit to be eaten.

FLEUR-DE-LIS, FLEURETTE, FLEURONNE, and FLEURY, in heraldry. See FLORY.

FLEXIBLE, in phyſics, is applied to bodies, that are capable of being bent, or changed from their natural form and direction. A body is not capable of being inflected or bent, unleſs the whole thereof be at reſt. In bending a body, it conſtitutes, as it were, two levers; and the point it is to be bent in, is a fulcrum: hence, as a moving power, the farther it is from the fulcrum, it acquires a greater force; the longer the flexible body is, the eaſier it is bent.

FLEXION, in anatomy, &c. is applied to the motion of an arm, or other member, whereby it is bent. The arm has a motion of flexion, and another of extenſion. The motion of flexion is, when the radius and humerus approach each other, and form an angle at the elbows.

FLEXOR, in anatomy, a name given to ſeveral muſcles in reſpect of their action, viz. the bending of the members, or joints, in oppoſition to the extenſors, which open and ſtretch them. See Syſtem of ANATOMY, Part III. Sect. XIII and XIV.

FLEXURE, or FLEXION, in geometry, is uſed to ſignify; that a curve is both concave and convex, with reſpect to a given right line, or a fixed point. And the point which limits the concavity and convexity, is called the point of contrary flexure.

FLIE, or FLY, that part of the mariner's compaſs on which the thirty two winds are drawn, and over which the needle is placed, and faſtened underneath.

FLIGHT, the act of a bird in flying; or the manner, duration, &c. thereof. The feathers of birds are admirably contrived and fitted for the eaſe and convenience of flight. Almoſt every kind of bird has its particular flight: the eagle's flight is the higheſt: the flight of the ſparrow hawk and vulture are noble, and are fit for high enterprize and combat. The flight of ſome birds is low, weak, tranſient, and, as they call it, *terra à terra*; the flight of the partridge and pheaſant is but of ſhort continuance; that of the dove is laboured; that of the ſparrow undulatory, &c.

FLINT, in natural hiſtory, a kind of ſemi-tranſparent, or quite opaque ſtones; generally of a roundiſh form, and covered with white cruſt; of a ſmooth, uniform ſhining texture; ſo hard, that they will ſtrike fire with ſteel.

FLINTS are of the claſs of earths called vitrifiable, becauſe theſe earths are generally employed, together with fixed alkali, as materials in the making of glaſs. See GLASS.

Breaking of FLINTS. The art of cutting, or rather breaking, flint-ſtones into uniform figures, is by ſome ſuppoſed to be one of the arts now loſt. That it was known formerly, appears from the ancient Bridewell at Norwich, from the gate of the Auguſtin friars at Canterbury, and that of St. John's Abbey, Colcheſter. But that the art is not loſt, and that the French know it, appears from the platform on the top of the royal obſervatory at Paris; which, inſtead of being leaded, is paved with flint cut or broke into regular figures.

FLIP, a ſort of ſailors drink, made of malt liquor, ſpirits, and ſugar mixed.

FLOAT, denotes a certain quantity of pieces of timber joined together with rafters athwart, thrown into a river, to be conveyed down the ſtream; and even ſometimes to carry burthens down a river with the ſtream. The invention of floats is of great uſe; it is ſaid to have been firſt put in execution at Paris, in the year 1618.

FLOAT *Boards*, thoſe boards fixed to water wheels of underſhot mills, ſerving to receive the impulſe of the ſtream, whereby the wheel is carried round.

It is a diſadvantage to have too great a number of float-boards; becauſe when they are all ſtruck by the water, in the beſt manner it can be brought to act againſt them, the ſum of all theſe impulſes will only be equal to the impulſe made againſt one float-board at right angles, by all the water coming out of the pen-ſtock, through the opening, ſo as to take place on the float-board. The beſt rule in this caſe is, to have juſt ſo many, that each of them may come out of the water as ſoon as poſſible, after it has received and acted with its full impulſe; or, which comes to the ſame thing, when the ſucceeding one is in a perpendicular direction to the ſurface of the water. As to the length of theſe float-boards, it may be regulated according to the breadth of the ſtream. See Deſaguliers, vol. ii. p. 425.

FLOATING *Bridge*, a bridge conſiſting of ſeveral boats covered with planks; which ought to be ſo ſolidly framed as to bear both horſes and cannon.

FLOATING, in huſbandry, is the drowning or watering of meadows.

FLOOD, a deluge or inundation of waters. See DELUGE.

FLOOD is alſo uſed in ſpeaking of the tide. When the water is at loweſt, it is called flood; when riſing, young, or old flood; when at higheſt, high flood; when beginning to fall, ebb water.

FLOOD *Mark*, the mark which the ſea makes on the ſhore, at flowing water, and the higheſt tide: it is alſo called high water mark.

FLOOR, in building, the underſide of a room, or that part we walk on. Floors are of divers ſorts; ſome of earth, ſome of brick, others of ſtone, others of boards, &c. Carpenters, by the word floor, underſtand as well the frame work of timber, as the boarding over it.

FLOOR *of a Ship*, ſtrictly taken, is only ſo much of her bottom which ſhe reſts on, when a-ground. Such ſhips as have long, and withal broad floors, lie on the ground with moſt ſecurity, and are not apt to ſeel, or tilt on one ſide; whereas others, which are narrow in the floor, or, in the ſea phraſe, cranked by the ground, cannot be grounded without danger of being overturned.

FLORA, the goddeſs of flowers, was, according to the poets, the wife of Zephyrus, and was firſt honoured among the Sabines; but, according to Lactantius, ſhe was a lady of pleaſure, who having gained large ſums of money by proſtituting herſelf, made the Roman people her heir, on condition that certain games, called floralia, might be annually celebrated on her birth day. Her image in the temple of Caſtor and Pollux was dreſſed in a cloſe habit, and ſhe held in her hands the flowers of peaſe and beans: but the modern poets and painters have been more laviſh in ſetting off her charms, conſidering that no parts of nature offered ſuch innocent and exquiſite entertainment to the ſight and ſmell, as the beautiful variety which adorns, and the odour which embalms, the floral creation.

FLORALES *Ludi*, or FLORAL *Games*, in antiquity, were games held in honour of Flora, the goddeſt of flowers. Theſe were celebrated with ſhameful debaucheries. The moſt licentious diſcourſes were not enough, but the courteſans were called together by the ſound of a trumpet, and made their appearance naked, and entertained the people with indecent ſhews and poſtures: the comedians appeared after the ſame manner on the ſtage. Val. Maximus relates, that Cato being once preſent in the theatre on this occaſion, the people were aſhamed to aſk for ſuch immodeſt repreſentations in his preſence; till Cato, appriſed of the reſervedneſs and reſpect with which he inſpired them, withdrew, that the people might not be diſappointed of their accuſtomed diverſion.

FLORID *Style*, is that enriched and heightened with figures and flowers of rhetoric. Longinus uſes the terms florid and affected ſtyle indifferently, and lays them down as quite contrary to the true ſublime.

FLORIN, as a money of account, is uſed by the Italian, Dutch, and German merchants and bankers, in keeping their books, and making up their accounts. But this florin admits of different diviſions. Fabian obſerves, the florins were not of ſo fine gold as the nobles and half-nobles of Edw. III.

FLORIST, a perſon curious or ſkilled in flowers; their kinds, names, characters, culture, &c. It is alſo applied to an author who writes what is called the flora of any particular place, that is, a catalogue of the plants and trees which are found ſpontaneouſly growing there. The Flora Laponica of Linnæus, and Flora Virginia of Gronovius, are works of this kind; and theſe authors, as the authors of thoſe works, are properly called floriſtæ.

FLOTA, or FLOTTA, *Fleet*; a name the Spaniards give particularly to the ſhips which they ſend annually from Cadiz, to the port of Vera Cruz, to fetch thence the merchandizes gathered in Mexico for Spain. It conſiſts of the captains, admiral, and patach, or pinnace, which go on the king's account; and about ſixteen ſhips, from four hundred to a thouſand tons, belonging to particular perſons. They ſet out from Cadiz about the month of Auguſt, and are eighteen or twenty months before they return. Thoſe ſent to fetch the commodities prepared in Peru, are called galleons. The name flotilla is given to a number of ſhips, which get before the reſt in their return, and give information of the departure and cargo of the flota and galleons.

FLOTAGES, all ſuch things as are floating on the top of the ſea, or great rivers, a word chiefly uſed in the commiſſions of water bailiffs.

FLOUNDER, in ichthyology, the Engliſh name of a ſpecies of the genus Pleuronectes. For the various ſpecies ſee PLEURONECTES.

FLOUR, the meal of any grain, but more particularly of wheat, ground and ſifted for the purpoſe of food. The grain itſelf is not only ſubject to be eaten by inſects in that ſtate, but when ground into flour it gives birth to another race of deſtroyers, who eat it unmercifully and increaſe ſo faſt in it, that it is not long before they wholly deſtroy the ſubſtance. The fineſt flour is moſt liable to breed them, eſpecially when ſtale or ill prepared; in this caſe, if it be examined in a good light, it will be perceived to be in a continual motion; and on a nicer inſpection, there will be found in it a great number of little animals of the colour of the flour, and very nimble. If a little of this flour be laid on the plate of the double microſcope, the inſects are very diſtinctly ſeen in great numbers, very briſk and lively, continually crawling over one another's backs, and playing a thouſand antic tricks together; whether for diverſion, or ſearch of food, it is not eaſily to be determined. Theſe animals are of an oblong ſlender form, their heads are furniſhed with a kind of trunk, or oblong hollow tube, by means of which they take in their food, and their body is compoſed of ſeveral rings. They do vaſt miſchief among the magazines of flour laid up for armies and other public uſes; when they have once taken poſſeſſion of a parcel of this valuable commodity, it is impoſſible to drive them out, and they increaſe ſo faſt, that the only method of preventing the total loſs of the parcel, is to make it up into bread as ſoon as can be. The way to prevent their breeding in the flour is to preſerve it from damp; nothing gets more injury by being put up damp than flour, and yet nothing is ſo often put up ſo. It ſhould be always carefully and thoroughly dried before it is put up, and the barrels alſo dried into which it is to be put: then if they are kept in a room tolerably warm and dry, they will preſerve it well. Too dry a place never does any hurt, though one too moiſt always ſpoils it. See MEAL.

Flour, when carefully analyzed, is found to be compoſed of three very different ſubſtances. The firſt and moſt abundant is pure ſtarch, or white fecule, inſoluble in cold but ſoluble in hot water, and of the nature of mucous ſubſtances; which, when diſſolved, form water-glues. The ſecond is the gluten, moſt of whoſe properties have been deſcribed under the article BREAD. The third is of a mild nature, perfectly ſoluble in cold water, of the nature of ſaccharine extractive mucous matters. It is ſuſceptible of the ſpirituous fermentation, and is found but in ſmall quantity in the flour of wheat. See BREAD, GLUTEN, STARCH, and SUGAR.

FLOWER, FLOS, among botaniſts, the moſt beautiful part of trees and plants, containing the organs or parts of fructification. Though no parts of plants are more generally known than their flowers, yet the definitions given by different authors of this word are very various, and neceſſary to be explained, in order to the underſtanding of their works.

Jungius defines it to be the moſt tender part of a plant, remarkable for its colour or form, or for both, and cohering with the fruit. But this author himſelf acknowledges his definition to be too limited, as there are ſeveral plants whoſe flowers are produced remote from their fruit. Mr. Ray, ſays the flowers cohere for the moſt part with the rudiments of the fruit; which is likewiſe a phraſeology too inaccurate to be admitted in definitions. Tournefort defines the flower to be a part of a plant very often remarkable for its peculiar colours, for the moſt part adhering to the young fruit, to which it ſeems to afford the firſt nouriſhment, in order to explicate its moſt tender parts: but this is ſtill a more indeterminate definition than the former. Pontedera defines a flower to be a part of a plant, unlike the reſt in form and nature. If the flower has a tube, it adheres to or is fixed very near the embryo, to the uſe of which it is ſubſervient; but if the flower has no tube, then its baſe does not adhere to the embryo. This definition is ſcarce intelligible, except to expert botaniſts. Juſſieu defines a flower to be compoſed of chives and a piſtillum, and to be of uſe in the generation of the plant: but this definition is too imperfect, as there are many plants in which the piſtillum are found at a great diſtance from the chives, many flowers which have no piſtillum, and many which have their chives. Vaillant has been happier in his definition.

He ſays, that flowers are the organs which conſtitute the ſexes of plants, which are ſometimes found naked, and without any covering; and that the petals which moſt of them have, are not eſſential to their uſe, but ſerve, and are intended, merely as covers for them: but yet, as theſe coats or coverings are the moſt conſpicuous and moſt beautiful parts of the flowers, theſe are to be called flowers, be they of whatever form or ſtructure, or colour; and whether they contain the organs of both ſexes in each individual, or only of one, or even but of ſome part of one, provided they are not of the ſame figure and colour with the leaves of the plant. The ſhorteſt and moſt expreſs definition, however, ſeems to be that of Martin; which is, that flowers are the organs of generation of both ſexes, adhering to a common placenta, together with their common covering; or of either ſex ſeparately with its proper coverings if it have any.

The parts of flowers are, 1. The piſtillum or ovary, which is the rudiment of the fruit, and is therefore properly the organ of generation. 2. The ſtyle, which is a body accompanying the ovary; either ariſing from the middle of it, or ſtanding as an axis in the middle, with the embryos of the ſeeds round it. 3. The ſummits, called alſo apices, and antheræ, which are thoſe bodies that contain the prolific powder analogous to the male ſperm of animals, and generally hung upon ſlender threads, which are called the chives. 4. The petals, commonly called the flower-leaves, which are thoſe tender fine coloured leaves that are generally the moſt conſpicuous parts of a flower. 5. The empalement or calyx, which is formed of theſe tender leaves that cover the outer parts of the flower. Flowers, according to the number of their leaves or petals, are called monopetalous, or one-leaved; dipetalous, or two-leaved, &c.

The ſtructure of different flowers is very various; but Dr. Grew has obſerved, that the far greater number of them have the empalement, foliation, chives, &c. Mr. Ray accounts that every perfect flower has the petals, ſtamina or chives, apices or ſummits, and the ſtyle or piſtil; and ſuch as want any of theſe he calls imperfect flowers. The greater number of plants have a flower cup; which is of a firmer ſtructure than their leaves, and ſerves for their ſupport.

Flowers, deſigned for medicinal uſe, ſhould be plucked when they are moderately blown, and on a clear day before noon: for conſerves, roſes muſt be taken in the bud.

Eternal FLOWER. See XERANTHEMUM.
Everlaſting FLOWER. See GNAPHALIUM.
FLOWER-*Fence*. See POINCIANA.
Sun-FLOWER. See HELIANTHUS.
Wind-FLOWER. See ANEMONE.
FLOWER-*de-Luce*. See IRIS.

FLOWERS, in heraldry. They are much uſed in coats of arms; and in general ſignify hope, or denote human frailty and momentary proſperity. See ROSE, &c.

FLOWERS, in chymiſtry. By this name are generally underſtood bodies reduced into very fine parts, either ſpontaneouſly, or by ſome operation of art; but the term is chiefly applied to volatile ſolid ſubſtances, reduced into very fine parts, or into a kind of meal by ſublimation. Some flowers are nothing elſe than the bodies themſelves, which are ſublimed entire, without ſuffering any alteration or decompoſition; and other flowers are ſome of the conſtituent parts of the body ſubjected to ſublimation.

Preſerving of **FLOWERS.** The method of preſerving flowers in their natural beauty through the whole year has been much ſought after by many people.

The flowers of plants are by much the moſt difficult parts of them to preſerve in any tolerable degree of perfection; of which we have inſtances in all the collections of dried plants, or *horti ſicci*. In theſe the leaves, ſtalks, roots, and ſeeds of the plants appear very well preſerved; the ſtrong texture of theſe parts making them always retain their natural form, and the colours in many ſpecies naturally remaining. But where theſe fade, the plant is little the worſe for uſe as to the knowing the ſpecies by it. But it is very much otherwiſe in regard to flowers; theſe are naturally by much the moſt beautiful parts of the plants to which they belong; but are ſo much injured in the common way of drying, that they not only loſe, but change their colours one into another, by which means they give a handle to many errors; and they uſually alſo whither up, ſo as to loſe their form and natural ſhape. The primroſe and cowſlip kinds are very eminent inſtances of the change of colours in the flowers of dried ſpecimens: for thoſe of this claſs of plants eaſily dry in their natural ſhape; but they loſe their yellow, and, inſtead of it, acquire a fine green colour much ſuperior to that of the leaves in their moſt perfect ſtate. The flowers of all the violet kind loſe their beautiful blue, and become of a dead white; ſo that in dried ſpecimens there is no difference between the blue flowered violet, and the white flowered kinds. Sir Robert Southwell recommends the following method to preſerve both flowers and fruit throughout the whole year. Take ſalt-petre one pound; armenian bole, two pounds; clean common ſand, three pounds. Mix all well together: then gather fruit of any kind that is not fully ripe, with the ſtalk to each; put theſe in, one by one, into a wide-mouthed glaſs, laying them in good order. Tie over the top with an oilcloth, and carry them into a dry cellar, and ſet the whole upon a bed of the prepared matter of four inches thick in a box. Fill up the remainder of the box with the ſame preparation; and let it be four inches thick all over the top of the glaſs, and all round its ſides. Flowers are to be preſerved in the ſame ſort of glaſſes, and in the ſame manner; and they may be taken up after a whole year as plump and fair as when they were buried.

FLOWER *de lis*, or *Flour de luce*, in heraldry, a bearing repreſenting the lily, called the *queen of flowers*, and the true hieroglyphic of royal majeſty; but of late it is become more common, being borne in ſome coats one, in others three, in others five, and in ſome *ſemee* or ſpread all over the eſcutcheon in great numbers. The arms of France are, three flower de lis or, in a field azure.

FLOWERING *of Bulbous Plants*. Theſe plants will grow and flower in water alone, without any earth, and make a very elegant appearance.

We daily ſee this practiſed in ſingle roots; but there is a method of doing it with ſeveral roots in the ſame veſſel. Take a common ſmall garden pot; ſtop the hole at the bottom with a cork, and lute in the cork with putty, that no water can get through; then fit a board to the top of the pot, and bore ſix or ſeven holes in it at equal diſtances, to place the bulbs in; and as many ſmaller ones near them to receive ſticks, which will ſerve to tie up the flowers. Then fill up the pot with water to the board; and place tulips, jonquils, narciſſus's, and the like plants in the root upon the holes, ſo that the bottom of the roots may touch the water: thus will they all flower early in the ſeaſon, and be much more beautiful than any pot of gathered flowers, and will laſt many weeks in their full perfection. After the ſeaſon of flowering is over, the roots will gradually ſhrink through the holes of the board, and get looſe into the water: but, inſtead of being ſpoiled there, they will ſoon increaſe in ſize; ſo that they cannot return through the holes, and will produce ſeveral off-ſets. It is natural to try from this the conſequence of keeping the roots under water during the whole time of their blowing; and in this way they have been found to ſucceed very well, and flower even ſtronger and more beautifully than when in the ground. They may thus, alſo, with proper care in the degree of heat in the room, be kept flowering from before Chriſtmas till March or April. It is not eaſy, in this laſt manner, to manage the keeping the boards under water; for which reaſon, it is better to procure ſome ſheet lead of about four pounds to the foot, and cut this to the ſize of the mouth of the pot. In this there ſhould be bored holes for the bulbs, and other holes for the ſticks: and, in order to keep the ſticks quite firm, it is proper to have another plate of lead ſhaped to the bottom of the pot, with holes in it, anſwering to thoſe of the upper plate made for the ſticks. The ſticks will by this means be always kept perfectly ſteady; and the roots, being kept under water by the upper plate of lead, will flower in the moſt vigorous and beautiful manner imaginable. Some have thought of adding to the virtues of the water by putting in nitre in ſmall quantities, and others have added earth and ſand at the bottom; but it has always been found to ſucceed better without any addition.

It may be more agreeable to ſome to uſe glaſs jars in this laſt method with the leads, inſtead of earthern pots. The bulbs ſucceed full as well in theſe; and there is this advantage that the progreſs of the roots is ſeen all the while, and they are managed better as to the ſupply of water. By repeated experiments in this way on dried bulbs, and on thoſe taken freſh out of the ground, the former have been found to ſucceed the beſt. For thoſe taken freſh out of the ground being full of moiſture, will not ſo ſoon, upon changing their element, be nouriſhed fully by a new one; and the fibres which they had ſtruck in the ground, always rot when put into the water, and new ones muſt be formed in their places; ſo that it requires more time for them to come to flowering. The bulbs themſelves will not rot in this manner; but they will never be ſo ſtrong as thoſe which were put into the water dry, which gradually fill themſelves with moiſture from it, and regularly plump up. The beſt method of managing the whole proceſs is this: Place the bulbs at firſt only on the ſurface of the water; for thus they will ſtrike out their fibres moſt ſtrongly. When they have ſtood thus ſix weeks, pour in the water ſo high as to cover them entirely, and keep them thus till they have done flowering.

Sometimes the roots will become mouldy in ſeveral parts while they ſtand above the water, and the cleaning them of it is to no purpoſe; for it will eat and ſpread the farther, and frequently eat through two or three of their coats. In this caſe they muſt be immediately covered with water; when the mould will be ſtopped, and the roots become ſound, and flower as well as thoſe which never had any ſuch diſtemper. If the roots are ſuffered to remain in water all the year, they will not decay: but will flower againſt their proper ſeaſon, and that as vigorouſly as thoſe which have been taken out and dried. The old fibres of thoſe roots never rot till they are ready to puſh forth new ones. It is found by experience, that the hyacinth, and many other plants, grow to a greater degree of perfection when thus in water, than when in the ground. There is a peculiar ſpecies of hyacinth called *Keyſer's jewel*: this never, or very rarely, produces ſeed-veſſels in the common way of flowering, in the ground; but it will often produce ſome pods when blown in water.

Mr. Miller has intimated, in the Philoſophical Tranſactions, that bulbs ſet in glaſſes grow weaker, and ſhould be renewed every other year: but it is found, that, when managed in this manner, and kept under water, at the time of taking them up, they are as large; and ſome of them larger, than when planted; and if theſe be dried at a proper ſeaſon, they will flower, year after year, as well as freſh ones.

Ranunculus and anemone roots have been found to ſhoot up their ſtalks very well in this way; but the flowers are uſually blaſted, which ſeems to ariſe from want of free air. Pinks will flower very well in this manner; auriculus alſo may, with care, be brought to flower, but not ſtrongly. Roſes, jeſſamines, and honeyſuckles, may alſo be made to flower this way, and will thrive and ſend out ſuckers; the beſt pieces to plant, are ſuckers cut off about three inches under ground, without any fibres. The ſucculent plants may alſo be raiſed this way; for inſtance, the opuntia or Indian fig. If a fragment of a leaf of this plant be cut and laid by to dry for a month till it is an abſolute ſkin, as ſoon as it is put in this manner into water, it begins to plump up, and ſoon ſends out fibrous roots, and produces new leaves as quickly as it would do in the ground.

This is the more ſingular in theſe ſorts of plants, becauſe in their natural ſtate in the ground, they cannot bear much water. This method of growing in water is not peculiar to the bulbous rooted ones, but others may even be raiſed from ſeed by it. A bean, or pea, ſet in this manner, will grow up to its proper ſtandard, and will flower and produce pods which will ripen their ſeed. The ſmaller ſeeds may be alſo raiſed in this manner, by the help of wool ſupport them.

No vegetable tranſplanted out of the earth into water will thrive kindly: but any plant, whether raiſed from the root or ſeed in water, may be tranſplanted to the earth, and will ſucceed very well. It may be poſſible, therefore, from this method of raiſing plants in water, to come at a better way than is uſually practiſed of raiſing ſome roots in the earth which are ſubject to rot there; ſuch as anemonies, ranunculuſes, and hyacinths. A bulb dropped by chance upon the ground, will ſtrike out both ſtronger and more numerous fibres than thoſe which are planted in the uſual way in the ground. On this principle, it may be proper to take out the earth of the bed where the bulbs are to ſtand at the time of planting them, to ſuch a depth as they are to be placed under it when ſet for flowering. The bulbs are then to be ſet in their places, on the ſurface of this low ground; and to ſtand there till they have ſhot out their fibres and their head: then the earth is to be added over them by degrees, till they are covered as high above the head as they are in the uſual manner of planting them: thus they would be preſerved from the danger of rotting; and their fibres would be much ſtronger, and conſequently they would draw more nouriſhment, and flower better, than in the common way. The common method of planting theſe roots renders them liable to be deſtroyed by either extreme of a wet or a dry ſeaſon. In the firſt caſe, they immediately rot, by the abundant moiſture they receive; and, in the ſecond, they become dry as a ſtick, and mouldy; ſo that they are infallibyl rotted by the firſt rain that falls afterwards.

The directions neceſſary to the ſucceſs of the bulbs planted in water are theſe. When the leaden falſe bottoms are fixed down tight within two or three inches of the bottom of the veſſel (which is only deſigned to hold the ſticks ſteady which are to ſupport the leaves and ſtalks), then lay on the lead upon which the bulbs are to reſt, placing the notched part oppoſite to that in the falſe bottom, as near as the ſticks, when placed, will ſuffer it; then place the bulbs one in each hole, and fill up with water to the upper lead. The bottom of the bulb will then touch the water; and as the water diminiſhes in quantity, keep it ſupplied with more up to the ſame height for a month or ſix weeks; in which time the bulbs will have ſhot ſtrong fibres. Then fill up the water about half an inch above the ſurface of the lead; and, by degrees, as the fibres ſtrengthen, and the plume ſhoots from the head, keep the water higher and higher, till at length the whole bulb is covered. The water is to be kept at this ſtandard till the ſeaſon for drying them returns. At the time of planting the bulbs, they muſt be carefully cleaned from any foulneſſes at the bottom, by ſcraping them with the point of a knife till the ſound part of the bulb appears; clear them likewiſe from any looſe ſkins, and even take off their brown ſkin till they appear white; otherwiſe this brown ſkin will tinge the water, and the growth will not ſucceed ſo well.

The notches in the ſide of each lead are intended to give eaſy paſſage to the water, that, if there ſhould be any foulneſs or ſediment in it, on ſhaking it a little it may all run through, and freſh water be put in its place. But this ſhifting the water need not be done more than once or twice in a winter, as there may be occaſion from the foulneſs; and when this is done, the ſides of the veſſel ſhould be cleaned with a painter's bruſh, and rinced out again, and the bulbs themſelves waſhed, by pouring water on them at a little diſtance.

At any time when the outer ſkins of the bulbs dry, they are to be pealed off, that they may not occaſion foulneſs in the water; and if any duſt or foul matter be at any time obſerved ſwimming on the ſurface, the method is to fill up the pot or veſſel to the rim, and let it run over: this will carry off that light foulneſs, and the water may afterwards be poured away to the proper ſtandard. Bulbs of equal bigneſs ſhould be planted together in the ſame pot, that they may all have the ſame benefit of the water. Narciſſuſes and hyacinths do well together; as alſo tulips and jonquils, and crocuſes and ſnow-drops.

FLOWERS, in gardening, are diſtinguiſhed into early, or ſpring flowers, which flouriſh in the months of March, April, and May. Of this claſs are the annemonies, daffodils, hyacinths, tulips, jonquils, cowſlips, primroſes, &c. Summer-flowers, which open in June, July, and Auguſt, as pinks, gilly-flowers, lilies, daiſies, campanulas, poppies, ſunflowers, &c. Autumnal, or late flowers, denote thoſe of September, and October; as the occulus chriſti, Indian pinks and roſes, pancy, flower-gentle, &c. Of theſe flowers, thoſe which ſubſiſt all the year, we mean in the ſtem, or root at leaſt, are called perennials. And thoſe which are to be planted or ſowed a-freſh every year, according to the ſeaſon, are called annuals.

FLOWERS, in the animal œconomy, denote women's monthly purgations, or menſes. Nicod derives the word in this ſenſe from *fluere*, q. d. *fluors*. Others will have the name occaſioned hence, that women do not conceive till they have had their flowers: ſo that theſe are a ſort of forerunners of their fruit.

FLOWERS, in rhetoric, are figures or ornaments of diſcourſe by the Latins called *floſculi*.

FLUID, an appellation given to all bodies whoſe particles eaſily yield to the leaſt partial preſſure, or force impreſſed. For the laws and properties of fluids, ſee HYDROSTATICS. There are various kinds of animalcules to be diſcerned in different fluids by the microſcope. Of many remarkable kinds of theſe, a deſcription is given under the article ANIMALCULE. All of theſe little creatures are eaſily deſtroyed by ſeparating them from their natural element.

Naturaliſts have even fallen upon ſhorter methods. A needle point, dipped in ſpirit of vitriol, and then immerſed into a drop of pepper water, readily kills all the animalcules; which, though before friſking about with great livelineſs and activity, no ſooner come within the influence of the acid particles, than they ſpread themſelves, and tumble down to all appearance dead. The like may be done by a ſolution of ſalt; only with this difference, that, by the latter application, they ſeem to grow vertiginous turning round and round, till they fall down. Tincture of ſalt of tartar, uſed in the ſame manner, kills them ſtill more readily; yet not ſo, but there will be apparent marks of their being firſt ſick and convulſed.

Inks deſtroy them as faſt as ſpirit of vitriol, and human blood produces the ſame effect. Urine, ſack, and ſugar, all deſtroy them, though not ſo faſt; beſides, that there is ſome diverſity in their figures and appearances, as they receive their deaths from this poiſon or that. The point of a pin dipped in ſpittle, preſently killed all the kinds of animalcules in puddle-water, as Mr. Harris ſuppoſes it will other animalcules of this kind.

All who are acquainted with microſcopic obſervations, know very well, that in water, in which the beſt glaſſes can diſcover no particle of animated matter, after a few grains of pepper or a fragment of a plant of almoſt any kind, has been ſome time in it, animals full of life and motion are produced; and thoſe in ſuch numbers, as to equal the fluid itſelf in quantity. When we ſee a numerous brood of young fiſhes in a pond, we make no doubt of their having owed their origin to the ſpawn, that is, to the eggs of the parents of the ſame ſpecies. What are we then to think of theſe? If we conſider the progreſs of nature in the inſect-tribes in general, and eſpecially in ſuch of them as are moſt analogous to theſe, we ſhall find it leſs difficult to give an account of their origin than might have been imagined.

A ſmall quantity of water taken from any ditch in the ſummer-months, is found to be full of little worms, ſeeming in nothing ſo much as in ſize to differ from the microſcopic animalcules. Nay, water, without theſe, expoſed in open veſſels to the heat of the weather, will be always found to abound with multitudes of them, viſible to the naked eye, and full of life and motion. Theſe we know, by their future changes, are the fly worms, of the different ſpecies of gnats, and multitudes of other fly ſpecies; and we can eaſily determine, that they have owed their origin only to the eggs of the parent fly there depoſited. Nay, a cloſer obſervation will at any time give ocular proof of this, as the flies may be ſeen laying their eggs there, and the eggs may be followed through all their changes, to the fly again. Why then are we to doubt but that the air abounds with other flies and animalcules as minute as the worms in thoſe fluids; and that theſe laſt are only the fly worms of the former, which, after a proper time ſpent in that ſtate, will ſuffer changes like thoſe of the larger kinds, and become flies like thoſe to whoſe eggs they owed their origin? Vid. Reaumur. Hiſt. Inſect. vol. iv. p. 431.

The differently medicated liquors made by infuſions of different plants, afford a proper matter for the worms of different ſpecies of theſe ſmall flies: and there is no reaſon to doubt, but that among theſe ſome are viviparous, others oviparous; and to this may be, in a great meaſure, owing the different time taken up for the production of theſe inſects in different fluids. Thoſe which are a proper matter for the worms of the viviparous fly, may be ſooneſt found full of them; as, probably, the liquor is no ſooner in a ſtate to afford them proper nouriſhment, than their parents place them there: whereas thoſe produced from the eggs of the little oviparous flies, muſt, after the liquor is in a proper ſtate, and they are depoſited in it in the form of eggs, have a proper time to be hatched, before they can appear alive. It is eaſy to prove, that the animals we find in theſe vegetable infuſions were brought thither from elſewhere. It is not leſs eaſy to prove, that they could not be in the matter infuſed any more than in the water in which it is infuſed. Notwithſtanding the fabulous accounts of ſalamanders, it is now well known, that no animal, large or ſmall, can bear the force of fire for any conſiderable time; and, by parity of reaſon, we are not to believe, that any inſect, or embryo inſect, in any ſtate, can bear the heat of boiling water for many minutes. To proceed to inquiries on this foundation; if ſeveral tubes filled with water, with a ſmall quantity of vegetable matter, ſuch as pepper, oak-bark, truffles, &c. in which, after a time, inſects will be diſcovered by the microſcope; and other like tubes be filled with ſimple water boiled, with water and pepper boiled together, and with water with the two other ingredients, all ſeparately boiled in it; when all theſe liquors come to proper time for the obſervation of the microſcope, all, as well thoſe which have been boiled, as thoſe which have not, will be found equally to abound with inſects; and thoſe of the ſame kind, in infuſions of the ſame kind, whether boiled or not boiled. Thoſe in the infuſions which had ſuſtained a heat capable of deſtroying animal-life, muſt therefore not have ſubſiſted either in the water, or in the matters put into it, but muſt have been brought thither after the boiling; and it ſeems by no way ſo probably, as by means of ſome little winged inhabitants of the air depoſiting their eggs or worms in theſe fluids.

On this it is natural to aſk, how it comes to paſs, that while we ſee myriads of the progeny of theſe winged inſects in water, we never ſee themſelves? The anſwer is equally eaſy, viz. becauſe we can always place a drop of this water immediately before the focus of the microſcope, and keep it there while we are at leiſure to examine its contents; but that is not the caſe with regard to the air inhabited by the parent-flies of theſe worms, which is an immenſe extent in proportion to the water proper for nouriſhing theſe worms; and conſequently, while the latter are cluſtered together in heaps, the former may be diſperſed and ſcattered. Nor do we want inſtances of this, even in inſects of a larger kind. In many of our gardens, we conſequently find veſſels of water filled with worms of the gnat kind, as plentifully, in proportion to their ſize, as thoſe of other fluids are with animalcules. Every cubic inch of water in theſe veſſels contains many hundreds of animals; yet we ſee many cubic inches of air in the garden not affording one of the parent flies.

But neither are we poſitively to declare that the parent flies of theſe animalcules are in all ſtates wholly inviſible to us; if not ſingly to be ſeen, there are ſome ſtrong reaſons to imagine that they may in great cluſters. Every one has ſeen in a clear day, when looking ſtedfaſtly at the ſky, that the air is in many places diſturbed by motions and convolutions in certain ſpots. Theſe cannot be the effects of imagination, or of faults in our eyes, becauſe they appear the ſame to all; and if we conſider what would be the caſe to an eye formed in ſuch a manner as to ſee nothing ſmaller than an ox, on viewing the air on a marſh fully peopled with gnats, we muſt be ſenſible, that the clouds of theſe inſects, though to us diſtinctly enough viſible, would appear to ſuch an eye merely as the moving parcels of air in the former inſtance do to us; and ſurely it is thence no raſh concluſion to infer, that the caſe may be the ſame, and that myriads of flying inſects, too ſmall to be ſingly the objects of our view, yet are to us what the clouds of gnats would be in the former caſe.

Nervous FLUID. See NERVOUS *Fluid.*

Elaſtic FLUIDS. See AIR, GAS, VAPOUR, &c.

FLUIDITY, is by Sir Iſaac Newton defined to be, that property of bodies by which they yield to any force impreſſed, and which have their parts very eaſily moved among one another. To this definition ſome have added, that the parts of a fluid are in a continual motion. This opinion is ſupported by the ſolution of ſalts, and the formation of tinctures. If a ſmall bit of ſaffron is thrown into a vial full of water, a yellow tincture will ſoon be communicated to the water to a conſiderable height, though the vial is allowed to remain at reſt; which indicates a motion in thoſe parts of the fluid which touch the ſaffron, by which its colouring matter is carried up.

With regard to water, this can ſcarce be denied; the conſtant exhalations from its ſurface ſhew, that there muſt be a perpetual motion in its parts from the aſcent of the ſteam through it. In mercury, where inſenſible evaporation does not take place, it might be doubted; and accordingly the Newtonian philoſophers in general have been of opinion, that there are ſome ſubſtances eſſentially fluid, from the ſpherical figure of their conſtituent particles. The congelation of mercury, however, by an extreme degree of cold, demonſtrates that fluidity is not eſſentially inherent in mercury more than in other bodies. That fluids have vacuities in their ſubſtance is evident, becauſe they may be made to diſſolve certain bodies without ſenſibly increaſing their bulk. For example, water will diſſolve a certain quantity of ſalt; after which it will receive a little ſugar, and after that a little alum, without increaſing its firſt dimenſions. Here we can ſcarce ſuppoſe any thing elſe than that the ſaline particles were interpoſed between thoſe of the fluid; and as, by the mixture of ſalt and water, a conſiderable degree of cold is produced, we may thence eaſily ſee why the fluid receives theſe ſubſtances without any increaſe of bulk. All ſubſtances are expanded by heat, and reduced into leſs dimenſions by cold: therefore, if any ſubſtance is added to a fluid, which tends to make it cold, the expanſion by the bulk of the ſubſtance added, will not be ſo much perceived as if this effect had not happened; and if the quantity added be ſmall, the fluid will contract as much, perhaps more, from the cold produced by the mixture, than it will be expanded from the bulk of the ſalt. This alſo may let us know with what theſe interſtices between the particles of the fluid were filled up; namely, the element of fire, or heat. The ſaline particles, upon their ſolution in the fluid, have occupied theſe ſpaces; and now the liquor, being deprived of a quantity of this element equal in bulk to the ſalt added, feels ſenſibly colder. As, therefore, there is ſcarce any body to be found, but what may become ſolid by a ſufficient degree of cold; and none but what a certain degree of heat will render fluid; the opinion naturally ariſes, that fire is the cauſe of fluidity in all bodies, and that this element is the only eſſentially fluid ſubſtance in nature. Hence we may conclude, that thoſe ſubſtances which we call fluids are not eſſentially ſo, but only aſſume that appearance in conſequence of an intimate union with the element of fire; juſt as gums aſſume a fluid appearance on being diſſolved in ſpirit of wine, or ſalts in water.

Upon theſe principles Dr. Black mentions fluidity as an effect of heat. The different degrees of heat which are required to bring different bodies into a ſtate of fluidity, he ſuppoſes to depend on ſome particulars in the mixture and compoſition of the bodies themſelves; which becomes extremely probable, from conſidering that we change the natural ſtate of bodies in this reſpect, by certain mixtures; thus, if two metals are compounded, the mixture is uſually more fuſible than either of them ſeparately.

It is certain, however, that water becomes warmer by being converted into ice; which may ſeem contradictory to this opinion. To this, however, the Doctor replies, that fluidity does not conſiſt in the degree of ſenſible heat contained in bodies, which will affect the hand or a thermometor; but in a certain quantity which remain in a latent ſtate. This opinion he ſupports from the great length of time required to melt ice; and to aſcertain the degree of heat requiſite to keep water in a fluid ſtate, he put 5 ounces of water into a Florence flaſk, and converted it into ice by means of a freezing mixture put round the flaſk. Into another flaſk of the ſame kind he put an equal quantity of water cooled down nearly to the freezing point, by mixing it with ſnow, and then pouring it off. In this he placed a very delicate thermometer; and found, that it acquired heat from the air of the room in which it was placed: ſeven degrees of heat were gained the firſt half-hour. The ice being expoſed to the ſame degree of heat, namely, the air of a large room without fire, it cannot be doubted that it received heat from the air as faſt as the water which was not frozen: but, to prevent all poſſibility of deception, he put his hand under the flaſk containing the ice, and found a ſtream of cold air very ſenſibly deſcending from it, even at a conſiderable diſtance from the flaſk; which undeniably proved, that the ice was all that time abſorbing heat from the air. Nevertheleſs, it was not till 11 hours, that the ice was half-melted, though in that time it had abſorbed ſo much heat as ought to have raiſed the thermometer to 140°; and even after it was melted, the temperature of the water was found ſcarce above the freezing point: ſo that, as the heat which entered could not be found in the melted ice, he concluded that it remained concealed in the water, as an eſſential ingredient of its compoſition.

FLUMMERY, a wholeſome ſort of jelly made of oat-meal. The manner of preparing it is as follows. Put three large handfuls of finely ground oat-meal to ſteep, for 24 hours, in two quarts of fair water: then pour off the clear water, and put two quarts of freſh water to it: ſtrain it through a fine hair-ſieve, putting in two ſpoonfuls of orange-flower water, and a ſpoonful of ſugar: boil it till it is as thick as haſty-pudding, ſtirring it continually while it is boiling, that it may be very ſmooth.

FLUENT, or flowing quantity, in the doctrine of fluxions, that quantity (whether line, ſurface, ſolid, &c.) which is continually increaſing, or decreaſing. Thoſe fluents, which are generated in the ſame time, or in equal times, or which begin together and end together, are called contemporary fluents, and their fluxions are called contemporary fluxions; and if two or more of theſe contemporary fluents are always equal, or in any invariable ratio to each other, their contemporary fluxions will likewiſe be equal, or in the ſame proportion, and vice verſa. See Syſtem of FLUXIONS.

FLUOR, in phyſics, a fluid; or, more properly, the ſtate of a body that was before hard or ſolid, but is now reduced by fuſion, or fire, into a ſtate of fluidity.

FLUOR, in mineralogy, a certain kind of ſtone which facilitates fuſion. They are of different colours, purple, green, yellow, &c. more or leſs tranſparent, which are commonly found in veins of ores, and ſerve as the matrix to the minerals which they envelope. Moſt of them affect a cubical form, but others are found in lumps which have no determinate ſhape.

FLUOR *Albus*, or *Uterinus*, a kind of flux, incident to women, called the whites. It conſiſts in an irregular, diſorderly diſcharge of ſome corrupt humour from the uterus, near the os internum and the vagina, ſometimes white and pale, like whey; ſometimes yellow, green, or blackiſh. At firſt, it is uſually mild, and harmleſs; but in time, it grows hot, ſharp and corroſive, and excoriates all the parts it touches. It is attended with a pain in the ſpina dorſi, a ſwelling of the feet and eyes, wearineſs, lumbago, a loſs of appetite, loathings, and unaccountable longings, change of complexion, &c. It generally proceeds from a relaxed habit, ariſing from indolence, extreme grief, or the immoderate uſe of coffee, tea, or other weak and watery diet; and ſometimes from exceſſive menſtrual diſcharges, abortions, &c.

FLUTE, an inſtrument of muſic, the ſimpleſt of all thoſe of the wind-kind. It is played on by blowing it with the mouth; and the tones or notes are changed by ſtopping and opening the holes diſpoſed for that purpoſe along its ſide. German Flute is an inſtrument entirely different from the common flute. Its ſound is exceeding ſweet and agreeable; and ſerves as treble in a concert.

FLUX, FLUXUS, in medicine, an extraordinary iſſue, or evacuation of ſome humour. Fluxes are various, and variouſly denominated, according to their ſeats, or the humours thus voided; as a flux of the belly, uterine flux, hepatic flux, ſaliva flux, &c. The flux of the belly is of four kinds which have each their reſpective denominations, viz. the *lientery*, or *fluxus lientericus*; the *coeliac*, or *fluxus chyloſus*; the *diarrhoea*; and the *dyſentery*, or *bloody flux*. A wound, or ſcarification acroſs the crown of the head, is uſed in Scotland, to cure fluxes and dyſenteries. Philoſoph. Tranſact. N° 312. See Syſtem of MEDICINE.

FLUX, in metallurgy, is ſometimes uſed ſynonimouſly with fuſion. For inſtance, an ore, or other matter, is ſaid to be in liquid flux, when it is completely fuſed. But the word flux is generally uſed to ſignify certain ſaline matters, which facilitates the fuſion of ores, and other matters which are difficultly fuſible in eſſays and reductions of ores. Fixed alkalis, nitre, borax, tartar, and common ſalt, are the ſaline matters of which fluxes are generally compoſed. But the word flux is more particularly applied to mixtures of different proportions of only nitre and tartar; and theſe fluxes are called by particular names, according to the proportions of theſe ingredients as white flux, crude flux, and black flux.

FLUXION, in medicine, a ſudden collection of morbid matter. The velocity by which a flowing quantity is increaſed by its generating motion. In arithmetic, the method of finding an infinitely ſmall quantity, which, being taken an infinite number of times, becomes equal to a given quantity. See Syſtem of FLUXIONS.

SYSTEM OF FLUXIONS.

INTRODUCTION.

THE method of Fluxions, by ſome termed the *differential calculus*, and by others the *modern Geometry*, is one of the greateſt, moſt ſubtle, and ſublime diſcoveries of this, or perhaps of any age: it opens a new world to us, and extends our views, as it were, to infinity; it carries our conceptions beyond the bounds that ſeemed to have been preſcribed to the human mind, at leaſt infinitely beyond thoſe to which the ancient geometry was confined. Sir I. Newton and M. Leibnitz, both claimed the invention thereof; and nothing can be more glorious for the method itſelf, than the zeal wherewith the partiſans of either ſide have aſſerted their title. The firſt time the method made its appearance in public, was in 1684, when M. Leibnitz gave the rules thereof in the Leipſic Acts of that year; but the demonſtrations he kept to himſelf. The two brothers, the Bernouillis, were preſently ſtruck with it, and found out the demonſtrations, though very difficult; and practiſed the calculus with ſurpriſing ſucceſs. However, M. Leibnitz began to propoſe his differential method in a letter, dated 21 Jan. 1677, in which he exactly purſues Dr. Barrow's method of tangents, publiſhed in 1670; and Sir I. Newton communicated his method of drawing tangents to Mr. Collins, in a letter dated 10 Dec. 1672; which letter, together with another dated 13 June 1676, were ſent to M. Leibnitz by Mr. Oldenburgh, in 1676. So that there is a ſtrong preſumption that he might avail himſelf of the information contained in theſe letters, and other papers tranſmitted with them, and alſo in 1675, before the publication of his own letter, containing the firſt hint of his differential method. And it ſufficiently appears, that ſir I. Newton had invented his method before the year 1669, and that he actually made uſe of it in his Compendium of Analyſis and Quadrature of Curves before that time. His attention ſeems to have been directed this way, even before the plague which happened in London in 1665 and 1666, when he was about 23 years of age: and therefore there is no foundation for the hint ſuggeſted by the authors of the French Encyclopedic Art. *Differentielle*, that ſir Iſaac borrowed the differential method from Dr. Barrow.

In the year 1711, M. Leibnitz complained to the Royal Society, that Dr. Keill had accuſed him of publiſhing the method of Fluxions invented by ſir I. Newton, under other names and characters. He inſiſted, that nobody knew better than ſir Iſaac himſelf, that he had ſtolen nothing from him; and required that Dr. Keill ſhould publicly diſavow the ill conſtruction which might be put on his words. The ſociety therefore appointed a committee to examine all the old letters, papers, &c. that had paſſed among the ſeveral mathematicians, relating to the point; and after a ſtrict examen of all the evidences that could be procured, gave in their report, "That M. Leibnitz was in London in 1673, and kept a correſpondence with Mr. Collins by means of Mr. Oldenburgh, till Sept. 1676, when he returned from Paris to Hanover, by way of London and Amſterdam: that it did not appear that M. Leibnitz knew any thing of the differential calculus before his letter of the 21ſt June, 1677, which was a year after a copy of a letter, wrote by ſir I. Newton, in the year 1672, had been ſent to Paris to be communicated to him, and above four years after Mr. Collins began to communicate that letter to his correſpondents; wherein the method of fluxions was ſufficiently explained, to let a man of his ſagacity into the whole matter: and that ſir I. Newton had even invented his method before the year 1669, and, of conſequence, fifteen years before M. Leibnitz had given any thing on the ſubject in the Leipſic Acts." And thence they concluded, that Dr. Keill had not at all injured M. Leibnitz in what he had ſaid. The ſociety printed this cenſure of theirs, together with all the pieces and materials relating thereto, under the title of Commercium Epiſtolicum de Analyſi Promota, Lond. 1712. This book was carefully diſtributed through Europe, to vindicate the title of the Engliſh nation to the diſcovery.

SECT. I.

NATURE OF FLUXIONS.

In the Doctrine of Fluxions, Quantities and Magnitudes are conſidered, not as compoſed of an infinite number of conſtituent parts, but as deſcribed by continued local motion. Thus a line is conceived as deſcribed by the motion of a point; a rectangle, as produced by the motion of a line, and in ſhort all Quantities of what kind ſoever may (by analogy) be conceived to be generated after the like manner. Hence the following

DEFINITIONS.

1ſt. Quantities that are conſidered as generated by continual increaſe, are named *fluents* or *flowing*, *variable* or *indeterminate* quantities; while thoſe quantities that are aſſumed as already perfect, and retaining the ſame value, are named *conſtant*, *ſtanding*, or *invariable* quantities. Thus in a circle, the diameter is a *conſtant* quantity; but the ſine, verſed ſine, coſine, &c. are variable quantities; ſo alſo in a Parabola the Latus Rectum is a conſtant quantity; but the Abſciſſa and Correſpondent Ordinate are variable quantities.

2d. The *velocity*, *celerity*, or *rate of increaſe*, of any generating quantity, (or the degree of quickneſs, or ſlowneſs, wherewith the new parts thereof do continually ariſe) is named its Fluxion. Thus when a line is deſcribed by the motion of a point, the generated line itſelf is the *fluent*, and the *velocity* or *celerity* of the moving point is its Fluxion; but though this holds with reſpect to the generating of a line (becauſe in this caſe the rate of increaſe is as the velocity of the moving point) yet the idea of a fluxion ought to be carefully diſtinguiſhed from that of the mere abſtracted velocity of a moving body; for in many caſes the *celerity* or *rate of increaſe* of a flowing quantity (which is the ſtrict idea of a fluxion) is far from being proportional to the ſimple velocity of the generating point or line, &c. Thus, if a triangle be ſuppoſed to be generated by the parallel motion of a line, from an angular point, formed by two other lines, the ſpaces or areas deſcribed with the ſame velocity in equal times, will not be equal, but will be augmented at each, in proportion as the triangle increaſes in altitude; and therefore the fluxions in different parts thereof, though generated with the ſame velocity of motion, will not be equal to each other, but will be every where as the reſpective altitudes. Further, more variable quantities are not always conſidered as growing or increaſing, after this manner; but ſometimes as perpetually diminiſhing, till they vaniſh, and then the *celerities*, or *rates of decreaſe*, are the fluxions, and the *quantities* thus *diminiſhing* are the *fluents*.

3d. The indefinitely ſmall portions of the fluent, which are generated in any indefinitely ſmall particles of time, are called *moments* or *increments*; or, if the fluent decreaſes, the portions continually deſtroyed are named *decrements*.

4th. The celerity, variation, or quickneſs of increaſe or decreaſe of any fluxion, is called the ſecond fluxion; and the like variation, &c. of a ſecond fluxion is named the third fluxion, &c.

5th. Contemporary fluents are thoſe which are ſuppoſed to be generated together, or in equal times.

6th. In any fluxionary equation, a quantity of the firſt order is that which has only one firſt fluxion in it; a quantity of the ſecond order has either one ſecond fluxion, or two firſt fluxions; a quantity of the third order contains either a third fluxion, the product of three firſt fluxions, or the product of a firſt and ſecond fluxion, &c.

THE ALGORITHM OF FLUXIONS.

It muſt be obſerved, that in this art, it is not ſtrictly the fluxions themſelves that are brought into operation, but the *relation* of the fluxions among one another; for we do not determine what are the poſitive celerities of increaſe or decreaſe of variable quantities, but what is their ratio or proportion to each other; it being all that is requiſite to come at the ſolution of our enquiries. But in fluxional operations, for the ſake of brevity, we frequently ſpeak of the relations of fluxions and fluents, as though the algebraic expreſſions, exhibiting ſuch relations, were abſolutely the proper fluxional and fluential quantities themſelves. Hence we frequently ſay that ſuch and ſuch expreſſions are the fluxions of ſuch and ſuch variable quantities, when we only mean that thoſe expreſſions exhibit the true proportion or relation of the fluxions compared with one another. Therefore, when ever we ſpeak of a *fluxion* or a *fluent*, in any operation, the ſame muſt be underſtood in the like relative ſenſe. Hence if any terms are put to denote the relation of the fluxions of certain flowing quantities, ſuch fluxional relation will be alſo truly repreſented by any other terms which have the ſame proportion to each other.

To determine the relation of fluxional quantities, the immortal inventor of this art advances the following Axiom.

AXIOM I.

"Fluxions are very nearly as the augments of their fluents, generated in equal, but very ſmall, particles of time; and to ſpeak correctly, they are in the firſt ratio of their naſcent augments, or the laſt ratio of the evaneſcent parts; but they may be expounded by any lines that are proportional to them."

Hence they are proportional to the generating increment at the very inſtant: not the increment to be generated in the ſucceeding interval, however ſmall; neither the increment already generated in the preceding interval, but that which comes into exiſtance at that moment of duration when the fluent is complete. Nevertheleſs, in caſes where the fluxion or celerity of increaſe is uniform, the fluxions may be expounded by the contemporary increments taken either before or after, becauſe the celerity by which the fluent increaſes is every where alike. Thus, if a line be deſcribed by the uniform motion of a point, the fluxion in every part thereof is the ſame; and the like holds with reſpect to the generating of a parallelogram by the uniform motion of a line, &c. Hence alſo this other General Axiom.

AXIOM II.

The increments by which any contemporary flowing quantities *would be* uniformly increaſed in a given portion of time, with the generating celerity at any propoſed poſition or inſtant (were they from thence to continue invariable or uniform) would be to each other in the ſame proportion as are the fluxions of thoſe quantities at that poſition or inſtant; conſequently by means of thoſe increments the relation of the fluxions are had.

The following Axiom alſo will be found uſeful in many uſes.

AXIOM III.

Quantities, which in any finite time converge to an equality, and before the end of that time approach nearer to each other than by any aſſignable difference, do at the laſt become perfectly equal. Should any deny this, and ſay they may not be equal; then let D be the ultimate difference, and ſo it will follow that they cannot approach nearer to equality than by this aſſigned difference D; but according to the conditions of the Axiom, they may before the end of the time approach nearer to equality than by any aſſignable difference, and conſequently nearer than by D. Hence, to deny the Axiom is abſurd, even though D be ſuppoſed ever ſo ſmall, for ſtill it will always involve a contradiction, except when D is poſitively nothing; and when D, the ſuppoſed difference, is nothing, the quantities muſt be perfectly equal.

Hence, in caſes where the fluxions are not uniform, their true ratio may be found by means of the increments generated in the equal preceding and ſucceeding ſmall particles of time; for they converge to an equality, the one after a direct motion, and the other by a retrograde motion; ſo that before they come to the point in queſtion, the generating increment and decrement become nearer to an equality than by any given difference; and conſequently by the above Axiom, they do at the laſt, or in the point where they coincide, become perfectly equal.

In the method of fluxions, the firſt letters of the alphabet, *a*, *b*, *c*, &c. are generally put to denote invariable or ſtanding quantities; and the laſt letters, *x*, *y*, *z*, &c. to repreſent the relation of fluents or variable or flowing quantities. Alſo, when *x* and *y*, &c. are made the repreſentatives of variable quantities, then thoſe letters with points over them ($\dot{x}$ and $\dot{y}$) denote the fluxions of *x* and *y*; or more properly *x* and *y* are put to expreſs the relation of the fluents, and $\dot{x}$ and $\dot{y}$ the relation of the fluxions: likewiſe the ſame letters twice pointed ($\ddot{x}$ and $\ddot{y}$) denote the relation of the ſecond fluxions of *x* and *y*; and $\dddot{x}$ and $\dddot{y}$ are, in like manner, put for the third fluxions of *x* and *y*, &c.

Furthermore x' denotes the moment, increment, or decrement, of *x*; and y', the moment, increment, &c. of *y*. Alſo x'' and y'' are the moments of the moments, or ſecond moments of *x* and *y*. Invariable quantities have no fluxion, or their fluxion is 0.

SECT. II.

DIRECT METHOD OF FLUXIONS.

By means of the foregoing Axioms, writers on Fluxions have demonſtrated the following Rules for performing fluxional operations.

Prob. I. *To find the Fluxion of any Power of a flowing Quantity.*

Rule. Multiply the fluxion of the root by the exponent of the power, and the product by a power of the ſame root, leſs by unity than the given exponent. Thus, the fluxion of x^3 is $3x^2\dot{x}$, of x^n $nx{-}^{n1}\dot{x}$; for the root of x^n is x, whoſe fluxion is $\dot{x}$; which, multiplied by the exponent n, and by a power of x leſs by unity than n, gives the above fluxion.

Prob. II. *To find the Fluxion of the Product of ſeveral variable Quantities multiplied together.*

Rule. Multiply the fluxion of each by the product of the reſt of the quantities, and the ſum of the products thus ariſing will be the fluxion ſought. Thus, the fluxion of xy, is $\dot{x}y+\dot{y}x$; that of xyz, is $xy\dot{z}+xz\dot{y}+yz\dot{x}$; and that of $xyzu$, is $xyz\dot{u}+xyu\dot{z}+xzu\dot{y}+yzu\dot{x}$.

Prob. III. *To find the Fluxion of a Fraction.*

Rule. From the fluxion of the numerator multiplied by the denominator, ſubtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the ſquare of the denominator. Thus, the fluxion of $\frac{x}{y}$ is $\frac{\dot{y}x-\dot{x}y}{y^2}$; that of $\frac{x}{x+y}$, is $\frac{\dot{x}\times\overline{x+y}-\overline{\dot{x}+\dot{y}}\times x}{\overline{x+y}|^2}=\frac{y\dot{x}-x\dot{y}}{\overline{x+y}|^2}$.

In complex caſes, let the particulars be collected from the ſimple rules, and combined together.

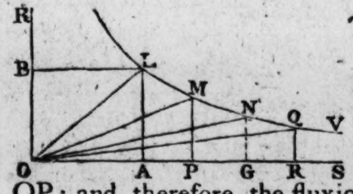
The fluxion of $\frac{x^2y^2}{z}$ is $\frac{\overline{2x^2y\dot{y}+2y^2x\dot{x}}\times z-x^2y^2\dot{z}}{x^2}$; for the fluxion of x^2 is $2x\dot{x}$, and of y^2 is $2y\dot{y}$, by Prob. I. and therefore the fluxion of x^2y^2 (by Prob. II.) $2x^2y\dot{y}+2y^2x\dot{x}$; from which, multiplied by z, (by Prob. III.) and ſubtracting from it the fluxion of the denominator z, multiplied by the numerator, and dividing the whole by the ſquare of the denominator, gives the above fluxion.

Prob. IV. *To find the* Fluxions *of Surd Quantities.* Suppoſe it required to find the fluxions of $\sqrt{2rx-xx}$, or $\overline{2rx-xx}|^{\frac{1}{2}}$. Suppoſe $\overline{2rx-xx}|^{\frac{1}{2}}=z$; then is $2rx-xx=zz$; and conſequently $r\dot{x}-x\dot{x}=z\dot{z}$; and, by diviſion, $\frac{r\dot{x}-x\dot{x}}{z}=\dot{z}=$ (by ſubſtitution) $\frac{r\dot{x}-x\dot{x}}{\sqrt{2rx-xx}}=$ to the fluxion of $\sqrt{2rx-xx}$.

Or, by the preceding rule, the fluxion of $\overline{2rx-xx}|^{\frac{1}{2}}$ will be $\frac{1}{2}\times\overline{2rx-2x\dot{x}}\times\overline{2rx-xx}|^{\frac{1}{2}-1}=\overline{r\dot{x}-x\dot{x}}+\overline{2rx-xx}|^{-\frac{1}{2}}=\frac{r\dot{x}-x\dot{x}}{\overline{2rx-xx}|^{\frac{1}{2}}}$.

If it be required to find the fluxion of $\overline{ay-xx}|^{\frac{1}{3}}$; for $\overline{ay-xx}|^{\frac{1}{3}}$ put z; then $ay-xx=z^{\frac{1}{3}}$, and $a\dot{y}-2x\dot{x}=\frac{1}{3}\dot{z}z^{-\frac{2}{3}}$; and multiplying by 3, $3a\dot{y}-6x\dot{x}=\dot{z}z^{-\frac{2}{3}}$; and, conſequently, $3az^{\frac{2}{3}}\dot{y}-6z^{\frac{2}{3}}x\dot{x}=\dot{z}$; equal (ſubſtituting $\overline{ay-xx}|^2=z^{\frac{2}{3}}$) $3a^3y^2\dot{y}-6a^2x^2y\dot{y}+3ax^4\dot{y}-6a^2y^2x\dot{x}+12ayx^3\dot{x}-6x^5\dot{x}=$ to the fluxion of $\overline{ay-xx}|^{\frac{1}{3}}$.

Prob. V. *To find the* Fluxion *of a Logarithm.* The fluxion of the hyperbolic logarithm of any quantity is equal to the fluxion of that quantity divided by the quantity itſelf; e. gr. the fluxion of the hyperbolic logarithm of x is $=\frac{\dot{x}}{x}$: for let L Q, *Figure* I. be an hyperbola, whoſe aſymptotes are OR and OS, and whoſe parameter is $AL=AO=1$: draw an ordinate PM parallel to AL, and the ſpace APML will be the hyperbolic logarithm of the line OP; and, therefore, the fluxion of the ſpace APML will be equal to the fluxion of the hyperbolic logarithm of the line OP. But the fluxion of this ſpace, OP being $=x$, and $PM=y$, is $=y\dot{x}$, and OP : AO :: LA : MP by the nature of the curve; i. e. $x:1::1:y=\frac{1}{x}$; therefore, $y\dot{x}=\frac{\dot{x}}{x}$. Then, from the nature of logarithms, the hyperbolic logarithm of 10, (viz. 2.30258, &c.) is to the common logarithm of 10, (viz. 1) as the hyperbolic logarithm of any number x, to the common logarithm of the ſame number x; i. e. L being made $=2.30258$, &c. L : 1 :: the hyperbolic logarithm of x : common logarithm of x: and therefore L : 1 :: the fluxion of the hyperbolic logarithm of x : the fluxion of the common logarithm of x : i. e. L : 1 :: $\frac{\dot{x}}{x}:\frac{\dot{x}}{Lx}$, which is the fluxion of the common logarithm of x; or becauſe $\frac{1}{L}=0.43429$, &c. the modulus of the Brigean or common form of logarithms, if $\frac{1}{L}$ be $=M$, the fluxion of the common logarithm of x (viz. $\frac{\dot{x}}{Lx}$) will be $=\frac{\dot{x}}{x}\times M$; or, the fluxion of the hyperbolic logarithm of any number multiplied by M or 0.43429, &c. is = the fluxion of the common logarithm of the ſaid number.



Prob. VI. *To find the* Fluxion *of an exponential or percurrent Quantity*, i. e. of a quantity having a variable exponent, as y^x. Suppoſe $y^x=u$; then, by the properties of logarithms, $x\times\log. y=\log. u$. And finding the fluxions of theſe terms, $\dot{x}\times\log. y+\frac{M\dot{y}}{y}\times x=\frac{M\dot{u}}{u}$, M being as in the preceding article: conſequently, the fluxion of y^x or $u=\frac{u\dot{x}}{M}\times\log. y+\frac{\dot{y}xu}{y}=\frac{\dot{x}}{M}\times y^x\times\log. y+xy^{x-1}\dot{y}$.

Second Fluxions are derived from the firſt, in the ſame manner as the firſt are from the flowing quantity. In the ſame way are third fluxions derived from ſecond fluxions, and fluxions of the fourth order from thoſe of the third, &c. Thus the fluxion of x^3, $3x^2\dot{x}$; its ſecond, $6x\dot{x}^2+3x^2\ddot{x}$ (by Prob. II.); and ſo on: but if $\dot{x}$ be invariable, $\ddot{x}=0$, and the ſecond fluxion of $x^3=6x\dot{x}^2$.

SECT. III.

THE APPLICATION OF THE DIRECT METHOD.

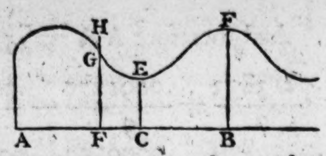
Prob. I. *To determine the Maxima and Minima.*

When a quantity increaſes, its fluxion is poſitive; when it decreaſes, it is negative; therefore, when it is juſt betwixt increaſing, its fluxion is $=0$.

Rule. Find the fluxion of the Equation, and put it $=0$, and the reſult will give an anſwer to the queſtion.

Examp. I. To determine the dimenſions of a cylindric meaſure, open at the top, which ſhall contain a given quantity of liquor, grain, &c. under the leaſt internal ſuperficies poſſible. Let the diameter $=x$, and the altitude $=y$; moreover, let p (3,14159, &c.) denote the periphery of the circle, whoſe diameter is unity, and let c be the given content of the cylinder. Then it will be $1:p::x:(px)$ the circumference of the baſe; which, multiplied by the altitude y, gives pxy for the concave ſuperficies of the cylinder. In like manner, the area of the baſe, by multiplying the ſame expreſſion into $\frac{1}{4}$ of the diameter x, will be found $=\frac{px^2}{4}$; which drawn into the altitude y, gives $\frac{px^2y}{4}$ for the ſolid content of the cylinder; which being made $=c$, the concave ſurface pxy will be found $=\frac{4c}{x}$, and conſequently the whole ſurface $=\frac{4c}{x}+\frac{px^2}{4}$: Whereof the fluxion, which is $-\frac{4c\dot{x}}{x^2}+\frac{px\dot{x}}{2}$ being put $=0$, we ſhall get $-8c\times px^3=0$; and therefore $x=2\sqrt[3]{\frac{c}{p}}$: Further, becauſe $px^3=8c$, and $px^2y=4c$, it follows, that $x=2y$; whence y is alſo known, and from which it appears, that the diameter of the baſe muſt be juſt the double of the altitude.

Examp.



Examp. II. To find the longeſt and ſhorteſt ordinates of any curve, GEF, *Figure* II. whoſe equation or relation which the ordinates bear to the abſciſſas is known.

Make AC the abſciſſa x, and CE the ordinate $=y$; take a value y in terms of x, and find its fluxion; which making $=0$, an equation will reſult whoſe roots give the value of x when y is a maximum or a minimum. To determine when it is a maximum and when a minimum, take the value of y, when x is a little more than the root of the equation ſo found, and it may be perceived whether it increaſes or decreaſes. If the equation has an even number of equal roots, y will be neither a maximum nor minimum when its fluxion is $=0$.

Art. II. *To draw a Tangent to any Curve.*

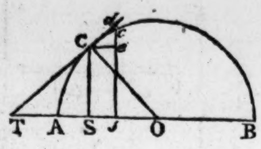


Figure III. When the abſciſſa C S of a curve moves uniformly from A to B, the motion of the curve will be retarded if it be concave, and accelerated if convex, towards A B; for a ſtraight line T C is deſcribed by an uniform motion, and the fluxion of the curve at any point is the ſame as the fluxion of the tangent, becauſe it would deſcribe the tangent if it continued to move equally from that point. Now if S*s* or C*e* be the fluxion of the baſe, C*d* will be the fluxion of the tangent, and *de* of the ordinate. And becauſe the triangles TSC, C*ed*, are equiangular, $de : ce :: \mathrm{CS} : \mathrm{ST}$, wherefore

Rule. Find a fourth proportional to the fluxion of the ordinate valued in terms of the abſciſſa, the fluxion of the abſciſſa, and the ordinate, and it determines the line ST, which is called the ſemi-tangent, and TC joined is a tangent to the curve.

Examp. To draw a right line C T, (ſee *fig.* 3.) to touch a given circle BCA in a given point C.

Let CS be perpendicular to the diameter AB, and put $\mathrm{AB}=a$, $\mathrm{AS}=x$, and $\mathrm{SC}=y$; then, by the property of the circle, y^2 (CS^2) $=\mathrm{BS}\times\mathrm{AS}$ ($=x\times\overline{a-x}$) $=ax-x^2$; whereof the fluxion being taken, in order to determine the ratio of $\dot{x}$, and $\dot{y}$, we get $2y\dot{y}=a\dot{x}-2x\dot{x}$; conſequently $\frac{\dot{x}}{\dot{y}}=\frac{2y}{a-2x}=\frac{y}{\frac{1}{2}a-x}$; which multiplied by y, gives $\frac{y\dot{x}}{\dot{y}}=\frac{y^2}{\frac{1}{2}a-x}=$ the ſubtangent ST. Whence (O being ſuppoſed the centre) we have OS ($\frac{1}{2}a-x$) : CS (y) :: CS (y) : ST; which we alſo know from other principles.

Art. III. *To determine Points of contrary Flexure in Curves.*
See *Fig.* II.

Suppoſing C to move uniformly from A to B, the curve GEF will be convex towards AB when the celerity of E increaſes, and concave when it decreaſes; therefore at the point where it ceaſes to be convex and begins to be concave, or the oppoſite way, the celerity of E will be uniform, that is, C E will have no ſecond fluxion. Therefore,

Rule. Find the ſecond fluxion of the ordinate in terms of the abſciſſa, and make it $=0$; and from the equation that ariſes you get a value of the abſciſſa, which determines the point of contrary flexure.

Examp. Let the nature of the cuve AGF be defined by $ay=a^{\frac{3}{2}}x^{\frac{1}{1}}+xx$, (the abſciſſa AF and the ordinate FG being, as uſual, repreſented by x and y reſpectively). Then $\dot{y}$, expreſſing the celerity of the point r, in the line FH, will be equal to $\frac{\frac{1}{2}a^{\frac{3}{2}}x^{-\frac{1}{2}}\dot{x}+2x\dot{x}}{a}$

Whoſe fluxion, or that of $\frac{1}{2}a^{\frac{3}{2}}x^{-\frac{1}{2}}+2x$ (becauſe a and $\dot{x}$ are conſtant) muſt be equal to nothing; that is, $-\frac{1}{4}a^{\frac{3}{2}}x^{-\frac{3}{2}}\dot{x}+2x=0$: Whence $a^{\frac{3}{2}}x^{-\frac{3}{2}}=8$, $a^{\frac{3}{2}}=8x^{\frac{3}{1}}64x^3=a^3$, and $x=\frac{1}{4}a=\mathrm{AF}$; therefore F G ($=\frac{a^{\frac{3}{2}}x^{\frac{1}{2}}+xx}{a}$) $=\frac{9}{16}a$: From which the poſition of the point G is given.

Art. IV. *To find the Radii of Curvature.*

The curvature of a circle is uniform in every point, that of every other curve continually varying: and it is meaſured at any point by that of a circle whoſe radius is of ſuch a length as to coincide with it in curvature in that point. All curves that have the ſame tangent have the ſame firſt fluxion, becauſe the fluxion of a curve and its tangent are the ſame. If it moved uniformly on from the point of contact, it would deſcribe the tangent. And the deflection from the tangent is owing to the acceleration or retardation of its motion, which is meaſured by its ſecond fluxion; and conſequently two curves which have not only the ſame tangent, but the ſame curvature at the point of contact, will have both their firſt and ſecond fluxions equal. It is eaſily proved from thence, that if y, x, and z, repreſent the abſciſſa, ordinate, and curve reſpectively, the radius curvature is $=\frac{\dot{z}^3}{-\dot{x}\ddot{y}}$.

Examp. Let the given curve be the common parabola, whoſe equation is $y=a^{\frac{1}{2}}x^{\frac{1}{2}}$: Then will $\dot{y}=\frac{1}{2}a^{\frac{1}{2}}\dot{x}x^{-\frac{1}{2}}=\frac{a^{\frac{1}{2}}\dot{x}}{2x^{\frac{1}{2}}}$, and (making $\dot{x}$ conſtant) $\ddot{y}=-\frac{1}{2}\times\frac{1}{2}a^{\frac{1}{2}}\dot{x}^2x^{-\frac{3}{2}}=\frac{-a^{\frac{1}{2}}\dot{x}^2}{4x^{\frac{3}{2}}}$: Whence $\dot{z}$ $\left(\sqrt{\dot{x}^2+\dot{y}^2}\right)=\frac{\dot{x}}{2}\sqrt{\frac{4x+a}{x}}$, and the radius of curvature $\left(\frac{\dot{z}^3}{-\dot{x}\ddot{y}}\right)=\frac{\overline{a+4}|^{\frac{3}{2}}}{2\sqrt{a}}$: Which at the vertex, where $x=0$, will be $=\frac{1}{2}a$.

SECT. III. INVERSE METHOD.

Prob. *From a given Fluxion to find a Fluent.*

This is done by tracing back the ſteps of the direct method. The fluxion of x is $\dot{x}$; and therefore the fluent of $\dot{x}$ is x: but as there is no direct method of finding fluents, this branch of the art is imperfect. We can aſſign the fluxion of every fluent; but we cannot aſſign the fluent of a fluxion, unleſs it be ſuch a one as may be produced by ſome rule in the direct method from a known fluent.

General Rule. Divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent ſo increaſed.

For, dividing the fluxion $nx{-}^{n1}\,\dot{x}$ by $\dot{x}$ the fluxion of the root x) it becomes nx^{n-1}; and, adding 1 to the exponent ($n-1$) we have nx^n; which, divided by n, given x^n, the true fluent of $nx^{n-1}\dot{x}$.

Hence (by the ſame rule) the fluent of $3x^2\dot{x}$ will be $=x^3$; that of $8x^2\dot{x}=\frac{8x^3}{3}$; that of $2x^5\dot{x}=\frac{x^6}{3}$; that of $y^{\frac{1}{2}}\dot{y}=\frac{2}{3}y^{\frac{3}{2}}$.

Sometimes the fluent ſo found requires to be corrected. The fluxion of x is $\dot{x}$, and the fluxion of $a+x$ is alſo $\dot{x}$, becauſe a is invariable and has therefore no fluxion. Now when the fluent of $\dot{x}$ is required, it muſt be determined, from the nature of the problem, whether any invariable part, as a, muſt be added to the variable part x. When fluents cannot be exactly found, they can be approximated, by infinite ſeries.

Examp. Let it be required to approximate the fluent of $\frac{\overline{a^2-x^2}|^{\frac{1}{2}}\times x^n}{\overline{c^4-x^2}|^{\frac{1}{2}}}$ in an infinite ſeries.

The value of $\frac{\overline{a^2-x^2}|^{\frac{1}{1}}}{\overline{c^2-x^2}|^{\frac{1}{2}}}$, expreſſed in a ſeries, is $\frac{a}{c}+\overline{\frac{a}{2c^3}-\frac{1}{2ac}}\times x^2+\overline{\frac{3a}{8c^5}-\frac{1}{4ac^3}-\frac{1}{8a^3c}}\times x^4+\overline{\frac{5a}{16c^7}-\frac{3}{16ac^5}-\frac{1}{16a^3c^3}-\frac{1}{16a^5c}}\times x^6+$ &c. Which value being therefore multiplied by $x^n x$, and the fluent taken (by the common method) we get $\frac{ax^{n+1}}{\overline{n+1}\times c}+\overline{\frac{a}{2c^3}-\frac{1}{2ac}}\times\frac{x^{n+3}}{n+3}+\overline{\frac{3a}{8c^5}-\frac{1}{4ac^3}-\frac{1}{8a^3c}}\times\frac{x^{n+5}}{n+5}+\overline{\frac{5a}{16c^7}-\frac{3}{16ac^5}-\frac{1}{16a^3c^3}-\frac{1}{16a^5c}}\times\frac{x^{n+7}}{n+7}+$ &c.

SECT. IV. APPLICATION OF THE INVERSE METHOD.

Art. I. *To find the Area of any Curve.*

Rule. Multiply the ordinate by the fluxion of the abſciſſa, and the product gives the fluxion of the figure, whoſe fluent is the area of the figure.

Examp. 1. Let the curve, whoſe area you will find, be the common parabola. Put u to repreſent the area, and $\dot{u}$ its fluxion. In which caſe the relation of the abſciſſa (x) and ordinate (y) being expreſſed $y^2=ax$ where a is the parameter) we thence get $y=a^{\frac{1}{2}}x^{\frac{1}{2}}$; and therefore $\dot{u}$ ($=y\dot{x}$) $=a^{\frac{1}{2}}x^{\frac{1}{2}}\dot{x}$: whence $u=\frac{2}{3}\times a^{\frac{1}{2}}x^{\frac{2}{3}}=\frac{2}{3}a^{\frac{1}{2}}x^{\frac{1}{2}}\times x=\frac{2}{3}yx$ (becauſe $a^{\frac{1}{2}}x^{\frac{1}{2}}=y$) $=\frac{2}{3}\times x\times y$. Hence a parabola is $\frac{2}{3}$ of a rectangle of the ſame baſe and altitude.

Examp. 2. Let the propoſed curve LMNQ (*fig.* 1.) be of ſuch a nature, that (ſuppoſing OA unity) the ſum of the areas LMPA and LNGO anſwering to any two propoſed abciſſas OP and OG, ſhall be equal to the area LQRA whoſe correſponding abſciſſa OR is equal to OP×OG, the product of the meaſures of the two former abſciſſas. Firſt, in order to determine the equation of the curve, (which muſt be known before the area is found), let the ordinates NG and OR, move parallel to themſelves, towards SV; and having put $\mathrm{GN}=y$, $\mathrm{QR}=z$, $\mathrm{OP}=a$, $\mathrm{OG}=s$, and $\mathrm{OR}=u$, the fluxion of the area LNGA will be repreſented by $y\dot{s}$, and that of the area LQRA by $z\dot{u}$; which two expreſſions muſt, by the nature of the problem, be equal to each other; becauſe the latter area exceeds the former by the area LMPA, which is here conſidered as a conſtant quantity: and it is evident, that two expreſſions, that differ only by a conſtant quantity, muſt always have equal fluxions. Since, therefore, $y\dot{s}$ is $= z\dot{u}$, and $u = as$, by hypotheſis, it follows, that $\dot{u} = a\dot{s}$, and that the firſt equation (by ſubſtituting $a\dot{s}$ for $\dot{u}$) will become $y\dot{s} = az\dot{s}$, or $y = az$; or, laſtly, $ys = zas$, that is, GN × OG : = QR + OR : therefore, GN : QR : : OR : OG; whence it appears, that every ordinate of the curve is reciproſally as its correſponding abcciſſa. Now to find the area of the curve ſo determined, put $OA = 1$, $AL = b$, and $AG = x$; then, ſince OG $(1+x)$: OA (1) : : AL (b) : GN (y) we have $y = \frac{b}{1+x}$, consequently $\dot{u}\ (= y\dot{x}) = \frac{b\dot{x}}{1+x}$ $= b \times \overline{\dot{x} - x\dot{x} + \dot{x}^2 z - n^3\dot{x} + \dot{x}x^4} -$ &c. Whence AGNL, the area itſelf will be $= b \times x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5}$, &c which was to be found.

Hence it appears, that as theſe areas have the ſame properties as logarithms, this ſeries gives an eaſy method of computing logarithms; and the fluent may be found by means of a table of logarithms, without the trouble of an infinite ſeries; and every fluxion whoſe fluent agrees with any known logarithmic expreſſion, may be found the ſame way. Hence the fluents of fluxions of the following forms are deduced.

The fluent of $\frac{\dot{x}}{\sqrt{x^2 \pm a^2}} =$ hyp. log. of $x + \sqrt{x^2 \pm a^2}$;

of $\frac{\dot{x}}{\sqrt{2ax+xx}} =$ hyp. log. $a \times x + \sqrt{2ax + x^2}$;

of $\frac{2a\dot{x}}{a^2 - x^2} =$ hyp. log. of $\frac{a+x}{a-x}$;

and of $\frac{2a\dot{x}}{x\sqrt{a^2 \pm x^2}} =$ hyp. log. $\frac{a - \sqrt{a^2 \pm x^2}}{a + \sqrt{a^2 \pm x^2}}$

ART. II. *To determine the Length of Curves.*

Fig. 3. Becauſe C de is a right-angled triangle, $Cd^2 = Ce^2 + de^2$; wherefore the fluxions of the abſciſſa and ordinate being taken in the ſame terms and ſquared, their ſum gives the ſquare of the fluxion of the curve; whoſe root being extracted, and the fluent taken, gives the length of the curve.

EXAMP. To find the length of a circle from its tangent. Make the radius AO (*fig.* 3.) $= a$, the tangent of AC $= t$, and its ſecant $= s$, the curve $= z$, and its fluxion $= \dot{z}$; becauſe the triangles OTC, OCS, are ſimilar, OT : OC : : OC : : OS; whence OS $= \frac{a^2}{s}$, and SA $= a - \frac{a^2}{s} = a - \frac{a^2}{\sqrt{a^2+t^2}}$; whoſe fluxion is $\frac{a^2 t\dot{t}}{\overline{a^2+t^2}|^{\frac{2}{3}}}$; and becauſe the triangles OTC, dCe are ſimilar, TC $(= t)$: TO $(= \sqrt{a^2+t^2})$: : Ce $= \left(\frac{a^2 t\dot{t}}{\overline{a^2+t^2}|^{\frac{2}{3}}}\right)$: C$d = \frac{a^2\dot{t}}{a^2+t^2} =$ fluxion of the curve. Now by converting this into an infinite ſeries, we have the fluxion of the curve $= \dot{t} - \frac{t^2\dot{t}}{a^2} + \frac{t^4\dot{t}}{a^4} - \frac{t^6\dot{t}}{a^6}$, &c. and conſequently $z = - \frac{t^3}{3a^2} + \frac{t^5}{5a^4} - \frac{t^7}{7a^6} + \frac{t^9}{9a^8}$ &c. $=$ AR. Where, if (for example ſake) AR be ſuppoſed an arch of 30 degrees, and AO (to render the operation more eaſy) be put $=$ unity, we ſhall have $t = \sqrt{\tfrac{1}{3}} = .5773502$ (becauſe Ob $\sqrt{\tfrac{3}{4}}$: bR $(\tfrac{1}{2})$: : O A (1) : AT $(t) = \sqrt{\tfrac{8}{2}}$) Whence,

$t^3 \quad (= t \times t^2 = t \times \tfrac{1}{3}) = .1924500$

$t^5 \quad (= t^3 \times t^2 = \frac{t^3}{3}) = .0641500$

$t^7 \quad (= t^5 \times {}^5t = \frac{t^2}{3}) = .0213833$

$t^9 \quad (= t^7 \times t^2 = \frac{t^7}{3}) = .0071277$

$t^{11} \quad (= t^9 \times t^2 = \frac{t^9}{3}) = .0023759$

$t^{13} \quad (= t^{11} \times t^2 = \frac{t^{11}}{3}) = .0007919$

$t^{15} \quad (= t^{13} \times t^2 = \frac{t^{13}}{3}) = .0002639$

&c.

And therefore $AR = .5773502 - \frac{.1934500}{3} + \frac{.0641500}{5} - \frac{.0213833}{7} + \frac{.0091277}{9} - \frac{.0023759}{11} + \frac{.0007919}{13} - \frac{.0002639}{15} + \frac{.0000879}{17} - \frac{.0000293}{19} + \frac{0000097}{21} - \frac{.0000032}{23} = .5235987$; for the length of an arch of 30 degrees, which multiplied by 6 gives 3.141592 + for the length of the ſemi periphery of the circle whoſe radius is unity.

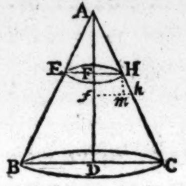
Other ſeries may be deduced from the verſed ſine, ſine, and ſecant; and theſe are of uſe for finding fluents which cannot be expreſſed in finite terms. Thus,

the fluent of	is equal to the arch whose	is $\frac{w}{a}$, and Radius Unity.
$\frac{\dot{w}}{\sqrt{2aw - w^2}}$	Verſed ſine	
$\frac{\dot{w}}{\sqrt{a^2 - w^2}}$	Right ſine	
$\frac{a\dot{w}}{{}^2 + w^2}$	Tangent	
$\frac{a\dot{w}}{w\sqrt{w^2 - a^2}}$	Secant	

ART. III. *To find the Contents of a Solid.*

Let the ſurface of the generating plane be multiplied by the ſpace it paſſes through in any time, the product will give a ſolid which is the fluxion of the ſolid required; the ſurface muſt therefore be computed in terms of x, which repreſents the line or axis on which it moves, and by its motion on which the fluxion is to be meaſured, and the fluent found will give the contents of the ſolid.

EXAMP. Let it be propoſed to find the content of a cone, ABC, *Fig.* IV.



Put the given altitude (AD) of the cone $= a$, and the ſemi-diameter (BD) of its baſe $= b$, the ſolid $= s$, its fluxion $= \dot{s}$ and the area of a circle, whoſe radius is unity, $= p$; then the diſtance (AF) of the circle EH, from the vertex A, being denoted by x, we have, by ſimilar triangles, as $a : b : : x :$ EF, $(y) = \frac{bx}{a}$. Whence in this caſe, $\dot{s}\ (= py^2\dot{x}) = \frac{pb^2x^2\dot{x}}{a^2}$; and conſequently $s = \frac{pb^2x^3}{3a^2}$; which, when $x = a$ (= AD) gives $\frac{pb^2a}{3}$ $(= p \times BD^2 \times \tfrac{1}{3}$ AD) for the content of the whole cone ABC; which appears from hence to be juſt $\tfrac{1}{3}$ of a cylinder of the ſame baſe and altitude.

ART. IV. *To compute the Surface of any Solid Body.*

The fluxion of the ſurface of the ſolid is equal to the periphery of the ſurface, by whoſe motion the ſolid is generated, multiplied by its velocity on the edge of the ſolid, and the computation is made as in the foregoing.

EXAMP. Let it be propoſed to determine the convex ſuperficies of a cone ABC, ſee *Fig.* 4.

Then, the ſemi-diameter of the baſe (BD, or CD) being put $= b$, the ſlanting line or hypothenuſe AC $= c$, and FH (parallel to DC) $= y$, AG $= z$, the ſurface $= w$, its fluxion $= \dot{w}$, and $p =$ the periphery of a circle whoſe diameter is unity, we ſhall, from the ſimilarity of the triangles A D C and H m h, have $b : c : : \dot{y}\ (mh) : x$ (H h) $= \frac{c\dot{y}}{b}$: whence $\dot{w}\ (2py\dot{z}) = \frac{2pcy\dot{y}}{b}$; and conſequently $w = \frac{pcy^2}{b}$. This, when $y = b$, becomes $= pcb = p \times DC \times AC =$ the convex ſuperficies of the whole cone ABC: which therefore is equal to a rectangle under half the circumference of the baſe and the ſlanting line.

The method of fluxions is alſo applied to find the centres of gravities, and oſcillation of different bodies; to determine the paths deſcribed by projectiles and bodies acted on by central forces, with the laws of centripetal force in different curves, the retardates given to motions performed in reſiſting medii, the attractions of bodies under different forms, the direction of wind which has the greateſt effect on an engine, and to ſolve many other curious and uſeful problems.

In this brief Syſtem of Fluxions, I have taken the ſtricteſt care to avoid Perplexity, and to make the Definitions and Axioms conſiſtent with Science, and pure Geometry. I have introduced the moſt uſeful Articles to which it is applicable, and extracted the moſt eſſential parts, from the valuable works of Sir Iſaac Newton, Maclaurin, Simpſon, Emerſon, and others, diſtinguiſhed for their Knowledge in the Science.

WILLIAM SQUIRE,
Late Maſter of the Academy in St. John's Lane.

FLY, in entomology, a large order of inſects, the diſtinguiſhing characteriſtic of which is, that their wings are tranſparent. By this they are diſtinguiſhed from beetles, butterflies, graſhoppers, &c. See SCARABÆUS, GRYLLUS, &c. Flies are ſubdivided into thoſe which have four, and thoſe which have two wings. Of thoſe with four wings there are ſeveral, genera or kinds; as the ant, abis, ichneumon, &c. See APIS, FORMICA, &c. Of thoſe with two wings, there are ſeveral kinds, as the gad-fly, gnat, &c. See GAD-*Fly*, &c. Thoſe who deſire a particular account of the anatomy, generation, ſtructure, and manifold ſubdiviſions of flies, may conſult the Syſtem of ENTOMOLOGY.

FLY, in mechanics, a croſs with leaden weights at its ends; or rather a heavy wheel at right angles to the axis of a windlaſs, jack, or the like; by means of which, the force of the power, whatever it is, is not only preſerved, but equally diſtributed in all parts of the revolution of the machine. See MECHANICS.

Vegetable FLY, a very curious and natural production chiefly found in the Weſt Indies. "Excepting that it has no wings, it reſembles the drone in ſize and colour more than any other Britiſh inſect. The credulous part of the natives believe that in the month of May it buries itſelf in the earth, and vegetates." Such was the account originally given of this extraordinary production. But ſeveral boxes of theſe flies having been ſent to Dr. Hill for examination, his report was this. "There is in Martinique a fungus of the clavaria kind, different in ſpecies from thoſe hitherto known. It produces ſoboles from its ſides, I call it therefore *clavaria ſobolifera*. It grows on putrid animal bodies, as our *fungus ex pede equino* from the dead horſe's hoof. The cicada is common in Martinque, and in its nympha ſtate, in which the old authors call it *tettigometra*; it buries itſelf under dead leaves to wait its change; and, when the ſeaſon is unfavourable, many periſh. The ſeeds of the clavaria find a proper bed on this dead inſect, and grow. The tettigometra is among the cicadæ in the Britiſh muſeum; the clavaria is juſt now known. This is the fact, and all the fact; though the untaught inhabitants ſuppoſe a fly to vegetate, and though there is a Spaniſh drawing of the plant's growing into a trifoliate tree, and it has been figured with the creature flying with this tree on its back." The ingenious Mr. Edwards has taken notice of this extraordinary production in his gleanings of Natural Hiſtory.

FLY-*Boat*, or *Flight*, a large flat-bottomed Dutch veſſel, whoſe burden is generally from 400 to 600 tons. It is diſtinguiſhed by a ſtern remarkably high, reſembling a Gothic turret, and by very broad buttocks below.

FLY-*Catcher*, the Engliſh name of the genus Muſicapa, according to Linnæus, the 73d genus of birds, and belonging to the 6th order called Paſſerds. Latham in his improved arrangement makes it the 38th genus, and the 3d order. For the deſcription, ſee MUSCICAPA. For the claſſification, ſee Syſtem of ORNITHOLOGY, for the repreſentation, ſee Plate III.

FLY-*Tree*, in natural hiſtory, a name given by the common people in America to a tree, whoſe leaves, they ſay, at a certain time of the year, produce flies. On examining theſe leaves about the middle of ſummer, the time at which the flies uſe to be produced, there are found on them a ſort of bags of tough matter, of about the ſize of a filbert, and of a duſky greeniſh colour; on opening one of theſe bags with a knife, there is uſually found a ſingle full-grown fly of the gnat kind, and a number of ſmall worms, which, in a day or two more, have wings, and fly away in the form of their parent. The tree is of the mulberry-kind, and its leaves are uſually very largely ſtocked with theſe inſect bags, and the generality of them are found to contain the inſects in the worm ſtate; when they become winged, they ſoon make their way out. The bags begin to appear when the leaves are young, and afterwards grow with them; but they never rumple the leaf, or injure its ſhape. They are of the kind of leaf galls, and partake in all reſpects, except ſize, of a ſpecies we have frequent on the large maple, or, as it is called the ſycamore. Philoſ. Tranſ. N° 431.

FLYING, the progreſſive motion of a bird, or other winged animal, in the liquid air. Flying is either natural, or artificial.

Natural FLYING is that performed by an apparatus, or ſtructure of parts, concerted for that end by nature herſelf. Such is that of moſt birds and inſects, and of ſome fiſhes. In Virginia and New-England they have monſtrouſly large flying beetles. Philoſoph. Tranſact. N° 127. And in Languedoc, graſhoppers about an inch long, wherewith the ground, in ſeveral parts, in the year 1685, was covered one third of a foot deep. Ibid. N° 182. The parts of birds, &c. chiefly concerned in flying, are the wings and tails: by the firſt the bird ſuſtains and wafts himſelf along; and by the ſecond, he is aſſiſted in aſcending and deſcending, to keep his body poiſed and upright, and to obviate the vacillations thereof. It is by the largeneſs and ſtrength of the pectoral muſcles, that birds are ſo well diſpoſed for quick, ſtrong, and continued flying. Theſe muſcles, which in men are ſcarce a ſeventieth part of the muſcles of the body, in birds exceed and outweigh all the other muſcles taken together. See COMPARATIVE ANATOMY, Sect. II.

The flying of birds is thus effected: The bird firſt bends his legs, and ſprings with a violent leap from the ground; then opens, or expands the jointures of his wings, ſo as to make a right line, perpendicular to the ſides of his body; thus, as the wings, with the feathers therein, conſtitute one continued lamina, being now raiſed a little, and vibrating the wings, with great force and velocity, perpendicularly againſt the air; the air, though a fluid, reſiſts thoſe ſucculſions, both from its natural inactivity and from its elaſticity, which makes it reſtore itſelf after it has been compreſſed; and re-act as much as it has been acted on: by ſuch means is the whole body of the bird protruded. The ſagacity of nature is very remarkable in the opening and recovering of the wing for freſh ſtroke. To do it directly, and perpendicularly, it muſt needs have a great reſiſtance to overcome; to avoid which the bony part, or bend, of the wing, into which the feathers are inſerted, moves ſideways, with its ſharp end foremoſt, the feathers following it like a flag. The reſiſtance the air makes to the withdrawing of the wings, and, conſequently, the progreſs of the bird will be ſo much the greater, as the waft, or ſtroke, of the fan of the wing is the longer; but as the force of the wing is continually diminiſhed by this reſiſtance, when the two forces come to be in equilibrio, the bird will remain ſuſpended in the ſame place; for the bird only aſcends ſo long as the arch of air, the wing deſcribes, makes a reſiſtance equal to the exceſs of the ſpecific gravity of the bird above the air: if the air, therefore, be ſo rare as to give way with the ſame velocity as it is ſtruck withal, there will be no reſiſtance, and, conſequently, the bird can never mount.

Artificial FLYING, is that attempted by men by the aſſiſtance of mechanics. The art of flying is one of the great deſiderata of mechanics: it has been attempted in divers ages; the diſcovery of it might prove of great ſervice, and alſo of great diſſervice to mankind. No body ſeems to bid ſo fair for that invention, as our famous friar Bacon, who lived upwards of five hundred years ago. He not only affirms the art feaſible, but aſſures us he himſelf knew how to make an engine, in which a man ſitting might be able to carry himſelf through the air like a bird; and affirms that there was another perſon who had actually tried it with ſucceſs. The ſecret conſiſted in a couple of large thin hollow copper globes, exhauſted of air, being much lighter than air, would ſuſtain a chair, whereon a perſon might ſit. The famous biſhop Wilkins was ſo confident of ſucceſs in this art, that he ſeems to intimate, that in future ages it will be as uſual to hear a man call for his wings when he is going a journey, as it is now to call for his boots.

FLYING *of Colours*, is uſed by painters to denote their want of durableneſs, which they expreſs by their ſtanding.

FLYING *Fiſh*, a name given by the Engliſh writers to ſeveral ſpecies of fiſh, which by means of their long fins have a method of keeping themſelves out of water for ſome time. The flying fiſh, moſt properly ſo called, is the exocœtus, a genus belonging to the order of aſdominales. For deſcription, ſee EXOCOETUS; for claſſification, ſee Syſtem of ICHTHYOLOGY.

FOAL, or COLT, the young of the horſe kind. The word colt, ſimply ſpoken, is, among the dealers, underſtood to mean the male kind; the female, or mare colt, being called a filly.

FOCUS, in geometry, and the conic ſections, is applied to certain points of the parabola, ellipſis, and hyperbola; wherein the rays reflected from all parts of theſe curves do concur or meet. See Syſtem of GEOMETRY.

FOCUS, in optics, is a point wherein ſeveral rays concur, and are collected; either after having undergone refraction, or reflection. It is thus called, becauſe the rays being here brought together, and united, their force and effect are increaſed; ſo that they become able to burn; accordingly it is in this point, that bodies are placed to ſuſtain the force of burning glaſſes, or mirrors. See Syſtem of OPTICS.

FODDER, any kind of meat for horſes, or other cattle: in ſome places hay and ſtraw mingled together are more peculiarly denominated fodder.

FŒTOR, in medicine, ſtinking or fetid effluvia, proceeding from the body or the parts thereof. Fœtors ariſe from ſtagnant, extravaſated, corrupted, or poiſoned humours: as alſo from any thing capable of attenuating and volatilizing the oils and ſalts, as abſtinence, heat, too much motion, acrimony of food, &c.

FOETOR *Oris*, a term uſed by medical writers to expreſs that ill ſmell in the mouth, actually, though often, improperly, called by us a ſtinking breath. This is a malady ariſing in different cauſes; as from the ſcurvy, and particularly that ſpecies, of it which affects the mouth, and is therefore called *ſtomacace*, from the French pox; from an ulceration, whether ſimple or fiſtulous, in the lungs, which is the caſe in conſumptions; from ulcers in the mouth; from caries or rottenneſs of the teeth, or from any other impurity of them; from crudities in the ſtomach ariſing from a bad digeſtion, and in particular, from a weakneſs about the left orifice of the ſtomach from which part the fœtid vapours will often ariſe in very great abundance.

Method of Cure. According to the different cauſes of this diſorder, it requires a very different method of cure. In caſes where it depends on the ſcurvy, pox, or other diſeaſes, thoſe diſeaſes are to be attacked by the proper medicines in order to its cure; when it ariſes from a carious tooth, there is no cure for it but drawing the tooth; when the impurities of the teeth occaſion it cleaning them proves a cure.

FOETUS, the young of all viviparous animals whilſt in the womb, and of oviparous animals before being hatched: the name is transferrable by botaniſts to the embryos of vegetables. In the human fetus are ſeveral peculiarities not to be found in the adult; ſome of them are as follows. 1. The arteries of the navel ſtring, which are continuations of the hypograſtics, are, after the birth, ſhrivelled up, and form the ligamenta umbilic. infer. 2. The veins of the navel ſtring are formed by the union of all the venaous-branches in the placenta, and paſſing into the abdomen become the falciform ligament of the liver. 3. The lungs, before being inflated with air, are compact and heavy; but after one inſpiration they become light, and as it were ſpongy: and it may be noted here, that the notion of the lungs ſinking in water before the child breathes, and of their ſwimming after the reception of air, are no certain proofs that the child had or had not breathed, much leſs than it was murdered: for the uninflated lungs become ſpecifically lighter than water as ſoon as any degree of putrefaction takes place in them; and this ſoon happens after the death of the child: beſides, where the utmoſt care hath been taken to preſerve the child, it hath breathed once or twice, and then died. 6. The thymus gland is very large in the fetus, but dwindles away in proportion as years advance. 7. The foramina ovale in the heart of a fetus, is generally cloſed in an adult. See Syſtem of MIDWIFRY; and for an account of the different opinions concerning the formation and growth of the fetus, ſee GENERATION.

FOG, or MIST, a meteor, conſiſting of groſs vapours, floating near the ſurface of the earth. Miſts, according to lord Bacon, are imperfect condenſations of the air, conſiſting of a large proportion of the air, and a ſmall one of the aqueous vapour: and theſe happen in the winter, about the change of the weather from froſt to thaw, or from thaw to froſt; but in the ſummer, and in the ſpring, from the expanſion of the dew. If the vapours, which are raiſed plentifully from the earth and waters, either by the ſolar or ſubterraneous heat, do at their firſt entrance into the atmoſphere, meet with cold enough to condenſe them to a conſiderable degree, their ſpecific gravity is by that means increaſed; and ſo they will be ſtopped from aſcending, and either return back, in form of dew or of drizzling rain; or remain ſuſpended ſome time in the form of a fog. Vapours may be ſeen on the high grounds as well as the low, but more eſpecially about marſhy places: they are eaſily diſſipated by the wind, as alſo by the heat of the ſun: they continue longeſt in the loweſt grounds, becauſe theſe places contain moſt moiſture, and are leaſt expoſed to the action of the wind. Hence we may eaſily conceive, that fogs are only low clouds, or clouds in the loweſt region of the air; as clouds are no other than fogs raiſed on high. See CLOUD. When fogs ſtink, then the vapours are mixed with ſulphureous exhalations, which ſmell ſo. Objects viewed through fogs, appear larger and more remote than through the common air. Mr. Boyle obſerves, that upon the coaſt of Coromandel, and moſt maritime parts of the Eaſt Indies, there are, notwithſtanding the heat of the climate, annual fogs ſo thick, as to occaſion people of other nations who reſide there, and even the more tender ſort of the natives, to keep their houſes cloſe ſhut up.

FOIBLE, a French term, frequently uſed alſo in our language. It literally ſignifies weak; and in that ſenſe is applied to the body of animals, and the parts thereof; as *foible* reins, *foible* ſight, &c. being derived from the Italian *fievole*, of the Latin *flebilis*, *to be lamented*, *pitied*. But it is chiefly uſed with us ſubſtantively to denote a defect, or flaw in a perſon, or thing. Thus we ſay, every perſon has his foible; and the great ſecret conſiſts in hiding it artfully: princes are gained by flattery, that is their foible: the foible of young people is pleaſure; the foible of old men is avarice; the foible of the great and learned is vanity; the foible of women and girls, coquetry, and an affectation of having gallants. It is a term alſo uſed in fencing, to denote the weakeſt part of a blade; in oppoſition to the fort, which is the ſtrongeſt.

FOIL, in fencing, denotes a blunt ſword, or one that has a button at the end covered with leather uſed in learning the art of fencing.

FOIL, among jewellers, a thin leaf of metal, placed under a precious ſtone, in order to make it tranſparent, to improve the colour, or to give it an agreeable different colour, either deep or pale. Thus the effect of giving luſtre is produced by the poliſh of the ſurface of the foil, which is colourleſs; but if a ſtone is wanted to be of a pale colour, a foil of that colour muſt be put under it: if deep, a dark one muſt be laid under it. Theſe foils are made either of copper, tin, gold, or gold and ſilver together: the copper foils are generally known by the name of Nuremberg or German foils.

FOILING, among hunters, the footing and treading of deer, which remains on the graſs, but ſcarce viſible.

FOLD *Net*, among ſportſmen, a ſort of net with which ſmall birds are taken in the night: there are two ſizes of it; the leaſt may be managed by one man, but the largeſt muſt be carried by two, and uſed thus: let the net be fixed on both ſides to two ſtrong poles about twelve feet long, each man holding one of them; let a third carry lights behind them, at the diſtance of two yards: the net ſhould be carried between the wind and birds, which rooſt on their perches with their breaſts againſt the wind: another perſon, who beats the buſhes on the other ſide of the hedge, will drive out the birds towards the light.

FOLIAGE, a cluſter or aſſemblage of flowers, branches, leaves, &c.

FOLIAGE is generally uſed for repreſentations of ſuch flowers, leaves, branches, rinds, &c. whether natural or artiſiical; uſed as enrichments on capitals, freezes, pediments, &c. See Syſtem of CHITECTURE, on the principles of the Art.

FOLIATING *of Looking Glaſſes*, is the ſpreading compoſition of ſomething which will firmly adhere to the back of the glaſs, and there reflect the image. This compoſition is called the foil, and is uſually made with quickſilver, mixed with tin, and ſome other ingredients. For the method of foliating looking glaſſes, ſee LOOKING-GLASS.

FOLIATION, in botany, &c. is uſed by Dr. Crew, to expreſs the aſſemblage of the folia, or petala, of a flower. The foliation is the moſt conſpicuous part of flowers, being that collection of fugaceous, coloured leaves, which conſtitutes the compaſs, or body of the flower.

FOLIO, in books of account, &c. ſignifies page. See Syſtem of BOOK-KEEPING, Sect. IV.

FOLIO, among bookſellers, a book in folio, or ſimply a folio, is that where the ſheet is only folded in two, each leaf making half a ſheet. Beneath the folio are the quarto, octavo, duodecimo, ſixteens, twenty-fours, &c.

FOLLY, according to Mr. Locke, conſiſts in the drawing of falſe concluſions from juſt principles; by which it is diſtinguiſhed from madneſs, which draws juſt concluſions from falſe principles. But this ſeems too confined a definition; folly, in its moſt general acceptation, denoting a weakneſs of intellect or apprehenſion, or ſome partial abſurdity in ſentiment or conduct.

FOMENTATION, a liquid medicine applied to any diſeaſed part, to reſolve, diſcuſs, ſoften, aſſwage, fortify, or conſtringe the ſame. Fomentations are either ſimple or compound.

Compound FOMENTATIONS, are decoctions of roots, leaves, flowers, and ſeeds, made in common water, or other proper liquor, to which are ſometimes added ſalts, exungiæ, oils, &c. To uſe, or apply them, they dip a hot linen cloth, or flannel, in the liquor, and ſpread it on the part affected.

Simple FOMENTATIONS, are thoſe made with luke-warm water, milk, oil, oxycrate, or the like liquors. Fomentations are alſo called local baths, or partial bathings; becauſe, being applied on a diſeaſed part, they have much the ſame effect as a bath, or half-bath, has on the whole body.

FONT, or *Baptiſmal* FONT, a ſtone or marble veſſel in churches ſerving to hold water to be uſed in adminiſtering the ſacrament of baptiſm.

FONT, or FOUNT, among printers, &c. a ſet, or quantity of characters, or letters, of each kind, caſt by a letter founder, and ſorted. We ſay, a founder has caſt a fount of pica, of engliſh, of pearl, &c. meaning that he has caſt a ſet of characters of theſe kinds. A complete fount does not only include the running letter, but alſo majuſcules, or large and ſmall capitals, ſingle letters, double letters, points, commas, lines, borders, head pieces, tail-pieces, and numeral characters. Founts are large or ſmall, according to the demand of the printer, who orders them by the hundred weight, or by ſheets. When the printer orders a fount of five hundred, he means that the fount ſhall weigh five hundred pounds. When he demands a fount of ten ſheets, it is underſtood, that with that fount he ſhall be able to compoſe ten ſheets, or twenty forms, without being obliged to diſtribute. The founder takes his meaſures accordingly; he reckons a hundred and twenty pounds for a ſheet, including the quadrates, &c. or ſixty pounds for a form, which is half a ſheet: not that the ſheet always weighs a hundred and twenty pounds, or the form ſixty pounds; on the contrary, it varies according to the ſize of the form; beſides, it is always ſuppoſed that there are letters left in the caſes. The letter founders have a kind of liſt, or tariff, whereby they regulate their founts: the occaſion thereof is, that ſome letters being in much more uſe, and oftener repeated, than others, their cells, or caſes, ſhould be better filled and ſtored, than thoſe of the letters which do not return ſo frequently. Thus the *o*, and *i*, for inſtance, are always in greater quantity than *k*, or *z*. This difference will be beſt perceived from a proportional compariſon of thoſe letters with themſelves, or ſome others. Suppoſe a *fount* of a hundred thouſand characters, which is a common *fount*; here the *a* ſhould have five thouſand; the *c*, three thouſand; the *e*, eleven thouſand; the *i*, ſix thouſand; the *m*, three thouſand; the *k*, only ſixty; and the *x*, *y*, and *z*, not many more. But this is only to be underſtood of the letters of the lower caſe; thoſe of the upper caſe having other proportions, which it would be, here, too long to inſiſt on.

FOOD, in the moſt extenſive ſignification of the word, implies whatever aliments are taken into the body, whether ſolid or fluid; but, in common language, it is generally uſed to ſignify only the ſolid part of our aliment.

Diſſertation on the Nature and Properties of Food.

The remarkable diſtinction of foods is into thoſe which are already aſſimilated into the animal nature, and ſuch as are not. Of the firſt kind are animal ſubſtances in general; which if not entirely ſimilar, are nearly ſo, to our nature. The ſecond comprehends vegetables, which are much more difficultly aſſimilated.

The moſt remarkable properties of different vegetable ſubſtances as food, are taken notice of under their different names: here we ſhall only compare vegetable foods in general with thoſe of the animal kind.

I. *In the Stomach.*

They differ remarkably, in that the vegetables always have a tendency to acidity, while animal-food of all kinds tend rather to alkaleſcency and putrefaction. Some animal-foods, indeed, turn manifeſtly acid before they putrify; and it has been aſſerted, that ſome degree of aceſcency takes place in every king of animal food before digeſtion. This aceſcency of animal food, however, never comes to any morbid degree, but the diſeaſe is always on the ſide of putreſcency. The aceſcency of vegetables is more frequent, and ought to be more attended to, than the alkaleſcency of animal food; which laſt, even in weak ſtomachs, is ſeldom felt; while aceſcency greatly affects both the ſtomach and ſyſtem.

With regard to their difference of ſolution: Heavineſs, as it is called, is ſeldom felt from vegetables, except from tough farinaceous paſte, or the moſt viſcid ſubſtances; while the heavineſs of animal food is more frequently noticed, eſpecially when in any great quantity. Difficulty of ſolution does not depend ſo much on firmneſs of texture, but on viſcidity; and hence it is more frequent in animal food, eſpecially in the younger animals. With regard to mixture:—There is no inſtance of difficult mixture in vegetables, except in vegetable oils; while animal foods, from both viſcidity and oilineſs, eſpecially the fatter meats, are refractory in this reſpect. Perhaps the difference of animal and vegetable foods might be referred to this head of mixture. For vegetable food continues long in the ſtomach, giving little ſtimulus: now the ſyſtem is affected in proportion to the extent of this ſtimulus, which is incomparably greater from the animal viſcid oily food, than from the vegetable, firmer, and more aqueous. However, there are certain applications to the ſtomach, which have a tendency to bring on the cold fit of fever, independent of ſtimulus, merely by their refrigeration: and this oftener ariſes from vegetables; as we ſee, in thoſe hot countries where intermittents prevail, they are oftener induced from a ſurfeit of vegetable than of animal food. A proof of this is, that when one is recovering of an intermittent, there is nothing more apt to cauſe a relapſe than cold food, eſpecially if taken on thoſe days when the fit ſhould return, and particularly aceſcent, fermentable vegetables, as ſallad, melons, cucumbers, &c. acido-dulces, &c. are the moſt frequent cauſes of epidemics; therefore, when an intermittent is to be avoided, we ſhun vegetable diet, and give animal foods, although their ſtimulus be greater.

II. *In the Inteſtines.*

When the putreſcency of animal food has gone too far, it produces an active ſtimulus, cauſing diarrhœa, dyſentery, &c. But theſe effects are but rare: whereas from vegetable food and its acid, which, united with the bile, proves a pretty ſtrong ſtimulus, they more frequently occur; but luckily, are of leſs conſequence, if refrigeration is not very great. In the autumnal ſeaſon, when there is a tendency to dyſentery, if it is obſerved that eating of fruits brings it on, it is rather to be aſcribed to their cooling than ſtimulating the inteſtines.

As to *ſtool*—Wherever neither putrefaction, nor acidity, has gone a great length, animal food keeps the belly more regular. Vegetable food gives a greater proportion of feculent matter, and, when exſiccated by the ſtomach and inteſtines, is more apt to ſtagnate, and produce ſlow belly and coſtiveneſs, than animal ſtimulating food; which, before it comes to the great guts, where ſtoppage is made, has attained a putrefactive tendency, and gives a proper ſtimulus: and thus thoſe who are coſtive from the uſe of vegetables, when they have recourſe to animal-food are in this reſpect better.

III. *In the Blood Veſſels.*

They both give a blood of the ſame kind, but of a different quality. Animal-food gives it in greater quantity, being in great part, as the expreſſion is, convertible in *ſuccum et ſanguinem*, and of eaſy digeſtion; whereas vegetable is more watery, and contains a portion of unconquerable ſaline matter, which cauſes it to be thrown out of the body by ſome excretion. Animal-food affords a more denſe ſtimulating elaſtic blood than vegetable: ſtretching and cauſing a greater reſiſtance in the ſolids, and again exciting their ſtronger action. It has been ſuppoſed, that aceſcency of vegetable food is carried into the blood-veſſels, and there exerts its effects; but the tendency of animal-fluids is ſo ſtrong to alkaleſcency, that the exiſtence of an acid acrimony in animal-blood ſeems very improbable. Animal-food alone will ſoon produce an alkaleſcent acrimony; and if a perſon who lives entirely on vegetables were to take no food for a few days, his acrimony would be alkaleſcent.

IV. *Quantity of Nutriment.*

We are next to take notice of the quantity of nutriment theſe different foods afford. Nutriment is of two kinds: the firſt repairs the waſte of the ſolid fibres; the other ſupplies certain fluids, the chief of which is oil. Now, as animal-food is eaſier converted, and alſo longer retained in the ſyſtem, and as it contains a greater proportion of oil, it will afford both kinds of nutriment more copiouſly than vegetables.

V. Laſtly, *The Different degrees of Perſpirability of theſe Foods.*

This is not yet properly determined. Sanctorius conſtantly ſpeaks of mutton as the moſt perſpirable of all food, and of vegetables as checking perſpiration. This is a conſequence of the different ſtimulus thoſe foods give to the ſtomach, ſo that perſons who live on vegetables have not their perſpiration ſo ſuddenly excited. In time of digeſtion, perſpiration is ſtopped from whatever food, much more ſo from cooling vegetables. Another reaſon why vegetables are leſs perſpirable is, becauſe their aqueo-ſaline juices determine them to go off by urine, while the more perfectly mixed animal food is more equally diffuſed over the ſyſtem, and ſo goes off by perſpiration. Hence Sanctorius's accounts may be underſtood; for vegetable aliment is not longer retained in the body, but moſtly takes the courſe of the kidneys. Both are equally perſpirable in this reſpect, viz. that a perſon living on either, returns once a day to his uſual weight; and if we conſider the little nouriſhment of vegetables, and the great tendency of animal food to corpulency, we muſt allow that vegetable is more quickly perſpired than animal food. As to the queſtion, whether man was originally deſigned for animal or vegetable food, ſee the article CARNIVOROUS.

With regard to the effects of theſe foods on men, it muſt be obſerved, that there are no perſons who live entirely on vegetables. The Pythagoreans themſelves eat milk; and thoſe who do ſo moſtly, as theſe Pythagoreans, are weakly, ſickly, and meagre, labouring under a conſtant diarrhœa and ſeveral other diſeaſes. None of the hardy, robuſt, live on theſe; but chiefly ſuch as gain a livelihood by the exertion of their mental faculties, as (in the Eaſt Indies) factors and brokers; and this method of life is now confined to the hot climates, where vegetable diet, without inconvenience, may be carried to great exceſs. Though it be granted, therefore, that man is intended to live on theſe different foods promiſcuouſly, yet the vegetable ſhould be in very great proportion. Thus the Laplanders are ſaid to live entirely on animal food: but this is contradicted by the beſt accounts; for Linnæus ſays, that beſides milk, which they take ſour, to obviate the bad effects of animal food, they uſe alſo calla, menianthes, and many other plants copiouſly. So there is no inſtance of any nation living entirely either on vegetable or animal food, though there are indeed ſome who live particularly on one or other in the greateſt proportion. In the cold countries, e. g. the inhabitants live chiefly on animal food, on account of the rigour of the ſeaſon, their ſmaller perſpiration, and little tendency to putrefaction. Of more importance, however, is the following than the former queſtion, viz.

In what Proportion Animal and Vegetable Food ought to be mixed?

Animal food certainly gives moſt ſtrength to the ſyſtem. It is a known aphoriſm of Sanctorius, that *pondus addit robur*; which may be explained from the impletion of the blood veſſels, and giving a proper degree of tenſion for the performance of ſtrong oſcillations. Now animal food not only goes a greater way in ſupplying fluid, but alſo gives the fluid more denſe and elaſtic. The art of giving the utmoſt ſtrength to the ſyſtem is beſt underſtood by thoſe who breed fighting cocks. Theſe people raiſe the cocks to a certain weight, which muſt bear a certain proportion to the other parts of the ſyſtem, and which at the ſame time is ſo nicely proportioned, as that, on loſing a few ounces of it, their ſtrength is very conſiderably impaired. Dr. Robinſon of Dublin has obſerved, that the force and weight of the ſyſtem ought to be determined by the largeneſs of the heart, and its proportion to the ſyſtem: for a large heart will give large blood-veſſels, while at the ſame time the viſcera are leſs, particularly the liver; which laſt being increaſed in ſize, a greater quantity of fluid is determined into the cellular texture, and leſs into the ſanguineous ſyſtem. Hence we ſee how animal food gives ſtrength, by filling the ſanguiferous veſſels. What pains we now beſtow on cocks, the ancients did on the Athletæ, by proper nouriſhment bringing them to a great degree of ſtrength and agility. It is ſaid that men were at firſt fed on figs, a proof of which we have from their nutritious quality; however, in this reſpect they were ſoon found to fall far ſhort of animal food; and thus we ſee, that men, in ſome meaſure, will work in proportion to the quality of their food. The Engliſh labour more than the Scots; and wherever men are expoſed to hard labour, their food ſhould be animal. Animal food, although it gives ſtrength, yet loads the body; and Hippocrates long ago obſerved, that the athletic habit, by a ſmall increaſe, was expoſed to the greateſt hazards. Hence it is only proper for bodily labours, and entirely improper for mental exerciſes; for whoever would keep his mind acute and penetrating, will exceed rather on the ſide of vegetable food. Even the body is oppreſſed with animal food; a full meal always produces dulneſs, lazineſs and yawning; and hence the feeding of gameſters, whoſe mind muſt be ready to take advantage, is always performed by avoiding a large quantity of animal food. Farther, with regard to the ſtrength of the body, animal-food in the firſt ſtage of life is hardly neceſſary to give ſtrength: in manhood, when we are expoſed to active ſcenes, it is more allowable; and even in the decline of life, ſome proportion of it is neceſſary to keep the body in vigour. There are ſome diſeaſes which come on in the decay of life, at leaſt are aggravated by it; among theſe the moſt remarkable is the gout. This, when it is in the ſyſtem, and does not appear with inflammation in the extremities, has pernicious effects there, attacking the lungs, ſtomach, head, &c. Now to determine this to the extremities, a large proportion of animal food is neceſſary, eſpecially as the perſon is commonly incapable of much exerciſe.

Animal Food.

Although it gives ſtrength, is yet of many hazards to the ſtyſtem, as it produces plethora and all its conſequences. As a ſtimulus to the ſtomach and to the whole ſyſtem, it excites fever, urges the circulation, and promotes the perſpiration. The ſyſtem, however, by the repetition of theſe ſtimuli, is ſoon worn out; and a man who has early uſed the athletic diet, is either early carried off by inflammatory diſeaſes, or, if he takes exerciſe ſufficient to render that diet ſalutary, ſuch an accumulation is made of putreſcent fluids, as in his after-life lays a foundation for the moſt inveterate chronic diſtempers. Therefore it is to be queſtioned, whether we ſhould deſire this high degree of bodily ſtrength, with all the inconveniences and dangers attending it. Thoſe who are chiefly employed in mental reſearches, and not expoſed to too much bodily labour ſhould always avoid an exceſs of animal-food. There is a diſeaſe which ſeems to require animal-food, viz. the hyſteric or hypochondriac; and which appears to be very much a-kin to the gout, affecting the alimentary canal. All people affected with this diſeaſe are much diſpoſed to aceſcency; which ſometimes goes ſo far, that no other vegetable but bread can be taken in, without occaſioning the worſt conſequences. Here then we are obliged to preſcribe an animal-diet, even to thoſe of very weak organs; for it generally obviates the ſymptoms. However, ſeveral inſtances of ſcurvy in exceſs have been produced by a long continued uſe of this diet, which it is always unlucky to be obliged to preſcribe; and when it is abſolutely neceſſary to preſcribe, it ſhould be joined with as much of the vegetable as poſſible, and when a cure is performed we ſhould gradually recur to that again. Next let us conſider the

Vegetable Diet.

The chief inconveniency of this is difficulty of aſſimilation; which, however, in the vigorous and exerciſed, will not be liable to occur. In warm climates, the aſſimilation of vegetable aliment is more eaſy, ſo that there it may be more uſed, and when joined to exerciſe gives a pretty tolerable degree of ſtrength and vigour; and though the general rule be in favour of animal diet, for giving ſtrength, yet there are many inſtances of their being remarkably produced from vegetable. Vegetable diet has this advantage, that it whets the appetite, and that we can hardly ſuffer from a full meal of it. Beſides the diſorders it is liable to produce in the *primæ viæ*, and its falling ſhort to give ſtrength, there ſeem to be no bad conſequences it can produce in the blood-veſſels; for there is no inſtance where its peculiar acrimony was ever carried there, and it is certainly leſs putrifiable than animal food; nor, without the utmoſt indolence, and a ſharp appetite, does it give plethora, or any of its conſequences: ſo that we cannot here but conclude, that a large proportion of vegetable food is uſeful for the generality of mankind. There is no error in this country more dangerous, or more common, than the neglect of bread: for it is the ſafeſt of vegetable aliment, and the beſt corrector of animal food; and, by a large proportion of this alone, its bad conſequences, when uſed in a hypochondriac ſtate, have been obviated. The French apparently have as much animal-food on their tables as the Britons; and yet, by a greater uſe of bread and the dried acid fruits, its bad effects are prevented; and therefore bread ſhould be particularly uſed by the Engliſh, as they are ſo voracious of animal food. Vegetable food is not only neceſſary to ſecure health, but long life: and, as we have ſaid, in infancy and youth we ſhould be confined to it moſtly; in manhood, and decay of life, uſe animal food, and near the end vegetable again. There is another queſtion much agitated, viz.

What are the Effects of Variety in Food?

Is it neceſſary and allowable, or univerſally hurtful; variety of a certain kind ſeems neceſſary; as vegetable and animal foods have their mutual advantages, tending to correct each other. Another variety, which is very proper, is that of liquid and ſolid food, which ſhould be ſo managed as to temper each other; and liquid food, eſpecially of the vegetable kind, is too ready to paſs off before it is properly aſſimilated, while ſolid food makes a long ſtay. But this does not properly belong to the queſtion, whether variety of the ſame kind is neceſſary or proper, as in animal-foods, beef, fiſh, fowl, &c. It doth not appear that there is any inconvenience ariſing from this mixture, or difficulty of aſſimulation, provided a moderate quantity be taken. When any inconvenience does ariſe, it probably proceeds from this, that one of the particular ſubſtances in the mixture, when taken by itſelf, would produce the ſame effect; and, indeed, it would appear, that this effect is not heightened by the mixture, but probably obviated by it. There are few exceptions to this, if any, e. g. taking a large proportion of aceſcent ſubſtances with milk. The coldneſs, &c. acidity, flatulency, &c. may appear; and it is poſſible that the coagulum, from the aceſcency of the vegetables, being ſomewhat ſtronger induced, may give occaſion to too long retention in the ſtomach, and to acidity in too great degree. Again, the mixture of fiſh and milk often occaſions inconveniences. The theory of this is difficult, though, from univerſal conſent, it muſt certainly be juſt. Can we ſuppoſe that fiſh gives occaſion to ſuch a coagulum as runnet? If it does ſo, it may produce bad effects. Beſides, fiſhes approach ſomewhat to vegetables, in giving little ſtimulus; and are accuſed of the ſame bad effects as theſe, viz. bringing on the cold fit of fever.

Thus much may be ſaid for variety. But it alſo has its diſadvantages, provoking to gluttony; this, and the art of cookery, making men take in more than they properly can digeſt: and hence, perhaps, very juſtly, phyſicians have univerſally almoſt preferred ſimplicity of diet; for, in ſpite of rules, man's eating will only be meaſured by his appetite, and ſatiety is ſooner produced by one than by many ſubſtances. But this is ſo far from being an argument againſt variety, that it is one for it, as the only way of avoiding a full meal of animal food, and its bad effects, is by preſenting a quantity of vegetables. Another mean of preventing the bad effects of animal food, is to take a large proportion of liquid; and hence the bad effects of animal food are leſs felt in Scotland, on account of their drinking much with it, and uſing broths, which are at once excellent correctors of animal food and preventives of gluttony.

With regard to the differences between animal foods, properly ſo called, the firſt regards their ſolubility, depending on a lax or firm texture of their different kinds.

I. *Solubility of Animal Food,*

Seems to deſerve leſs attention than is commonly imagined; for there are many inſtances of perſons of a weak ſtomach incapable of breaking down the texture of vegetables, or even of diſſolving a light pudding, to whom hung beef, or a piece of ham, was very grateful and eaſily digeſted. None of the theories given for the ſolution of animal-food in the human ſtomach ſeem to have explained that proceſs ſufficiently. Long ago has been diſcarded the ſuppoſition of an active corroſive menſtruum there; and alſo the doctrine of trituration, for which, indeed, there ſeems no mechaniſm in the human body; and, till lately, phyſicians commonly agreed with Boerhaave in ſuppoſing nothing more to be neceſſary than a watery menſtruum, immoderate heat, and frequent agitation. This will account for ſolution in ſome caſes, but not entirely. Let us try to imitate it out of the body with the ſame circumſtances, and in ten times the time in which the food is diſſolved in the ſtomach we ſhall not be able to bring about the ſame changes. Take the coagulated white of an egg, which almoſt every body can digeſt, and yet no artifice ſhall be able to diſſolve it. Hence, then, we are led to ſeek another cauſe for ſolution, viz. fermentation; a notion indeed, formerly embraced, but, on the introduction of mechanical philoſophy, induſtriouſly baniſhed, with every other ſuppoſition of that proceſs taking place at all in the animal œconomy. Many of the ancients imagined this fermentation to be putrefactive. But this we deny, as an acid is produced; though hence the fermentation might be reckoned the vinous, which, however, ſeems always to be morbid. Neither, indeed is the fermentation purely acetous, but modified by putreſcence; for Pringle has obſerved, that animal-matters raiſe and even expedite the acetous proceſs. The fermentation, then, in the ſtomach is of a mixed nature, between the acetous and the putrefactive, mutually modifying each other; though, indeed, in the inteſtines, ſomewhat of the putrefactive ſeems to take place, as may be obſerved from the ſtate of the fæces broke down, and from the little diſpoſition of ſuch ſubſtances to be ſo, which are not liable to the putrefactive proceſs, as the firmer parts of vegetables, &c. Upon this view ſolution ſeems to be extremely eaſy, and thoſe ſubſtances to be moſt eaſily broke down which are moſt ſubject to putrefaction. But ſolution alſo depends on other circumſtances, and hence requires a more particular regard.

1. There is a difference of ſolubility with reſpect to the manducation of animal-food, for which bread is extremely neceſſary, in order to keep the more ſlippery parts in the mouth till they be properly comminuted. See the Article Bread. From want of proper manducation perſons are ſubject to eructations; and this more frequently from the firm vegetable foods, as apples, almonds, &c. than from the animal, though, indeed, even from animal food, very tendinous, or ſwallowed in unbroken maſſes, ſuch ſometimes occur. Manducation is ſo much connected with ſolution, that ſome, from imperfectly performing that, are obliged to belch up their food, remanducate it, and ſwallow it again before the ſtomach can diſſolve it, or proper nouriſhment be extracted. Another proof of our regard to ſolubility, is our rejecting the firmer parts of animal food, as bull-beef, and generally carnivorous animals.

2. Its effects with regard to ſolubility, ſeem alſo to be the foundation of our choice between fat and lean, young and old meats. In the lean, although, perhaps, a ſingle fibre might be ſufficiently tender, yet theſe, when collected in faſciculi, are very firm and compact, and of difficult ſolution; whereas in the fat there is a greater number of veſſels, a greater quantity of juice, more interpoſition of cellular ſubſtance, and conſequently more ſolubility. Again, in young animals, there is probably the ſame

number of fibres as in the older, but theſe more connected: whereas, in the older, the growth depending on the ſeparation of theſe, and the increaſe of veſſels and cellular ſubſtance, the texture is leſs firm and more ſoluble; which qualities, with regard to the ſtomach, are at that time too increaſed, by the increaſed alkaleſcency of the animal. To this alſo may be referred our choice of caſtrated animals, viz. on account of their diſpoſition to fatten after the operation.

3. It is with a view to the ſolubility, that we make a choice between meats recently killed, and thoſe which have been kept for ſome time. As ſoon as meat is killed, the putrefactive proceſs begins; which commonly we allow to proceed for a little, as that proceſs is the moſt effectual breaker down of animal matters, and a great aſſiſtance to ſolution. The length of time during which meat ought to be kept, is proportioned to the meat's tendency to undergo the putrid fermentation, and the degree of thoſe circumſtances which favour it: thus in the Torrid Zone, where meat cannot be kept above four or five hours, it is uſed much more recent than in theſe northern climates.

4. Boiled or roaſted meats create a difference of ſolution. By boiling we extract the juices interpoſed between the fibres, approximate them more to each other, and render them of more difficult ſolubility; which is increaſed too by the extraction of the juices, which are much more alkaleſcent than the fibres: but when we want to avoid the ſtimulus of alkaleſcent food, and the quick ſolution, as in ſome caſes of diſeaſe, the roaſted is not to be choſen. Of roaſted meats it may be aſked, which are more proper, thoſe which are moſt or leaſt roaſted? That which is leaſt done is certainly the moſt ſoluble: even raw meats are more ſoluble than dreſſed, as Dr. Cullen was informed by a perſon who from neceſſity was obliged, for ſome time, to eat ſuch. But at the ſame time that meats little done are very ſoluble, they are very alkaleſcent; ſo that, wherever we want to avoid alkaleſcency in the primæ viæ, the moſt roaſted meats ſhould be choſen. Thoſe who throw away the broths of boiled meat do very improperly; for, beſides their ſupplying a fluid, from their greater alkaleſcency, they increaſe the ſolubility of the meat. Here we ſhall obſerve, that pure blood has been thought inſoluble. Undoubtedly it is very nutritious; and though out of the body, like the white of eggs, it ſeems very inſoluble, yet, like that too, in the body it is commonly eaſily digeſted. Moſes very properly forbad it the Iſraelites, as, in warm countries, it is highly alkaleſcent; and even here, when it was uſed in great quantity, the ſcurvy was more frequent: but to a moderate uſe of it, in theſe climates, no ſuch objection takes place. 5. Solubility is varied from another ſource, viz. viſcidity of the juice of aliment. Young animals, then, appear more ſoluble than old, not only on account of the compaction and firmneſs of texture in the latter, but alſo their greater viſcidity of juice. And nothing is more common, than to be longer oppreſſed from a full meal of veal, than from the ſame quantity of beef, &c. Upon account, too, of their greater viſcidity of juice, are the tendinous and ligamentous parts of animals longer retained than the purely muſcular, as well as on account of their firmneſs of texture. Even fiſhes, whoſe muſcular parts are exceedingly tender, are, on account of their gluey viſcocity, longer of ſolution in the ſtomach. And eggs, too, which are exceedingly nouriſhing, have the ſame effect, and cannot be taken in great quantity: for the ſtomach is peculiarly ſenſible to gelatinous ſubſtances; and by this means has nature perhaps taught us, as it were by a ſort of inſtinct, to limit ourſelves in the quantity of ſuch nutritive ſubſtances.

6. With regard to ſolution, we muſt take in the oils of animal-food; which, when tolerably pure, are the leaſt putreſcent part of it, and, by diminiſhing the coheſion of the fibres, render them more ſoluble. On this laſt account is the lean of fat meat more eaſily diſſolved than other lean. But when the meat is expoſed to much heat, this oil is ſeparated, leaving the ſolid parts leſs eaſily ſoluble, and becoming itſelf empy-reumatic, ranceſcent, and of difficult mixture in the ſtomach. Fried meats, from the reaſons now given, and baked meats, for the ſame, as well as for the tenacity of the paſte, are preparations which diminiſh the ſolubility of the food. From what has been ſaid, the preparation of food by fattening it, and keeping it for ſome time after killed, although it may adminiſter to gluttony, will yet, it muſt be confeſſed, increaſe the ſolution of the food.

II. *The Second Difference of Animal Food is with regard to Alkaleſcency.*

1. From their too great alkaleſcency we commonly avoid the carnivorous animals, and the feræ; and chooſe rather the granivorous. Some birds, indeed, which live on inſects, are admitted into our food; but no man, without nauſea, can live upon theſe alone for any length of time. Fiſhes, too, are an exception to this rule, living almoſt univerſally on each other. But in theſe the alkaleſcency does not proceed ſo far; whether from the viſcidity of their juice, their want of heat, or ſome peculiarity in their economy, is not eaſy to determine.

2. Alkaleſcency is determined by difference of age. The older animals are always more alkaleſcent than the young, from their continual progreſs to putrefaction. Homberg always found, in his endeavours to extract an acid from human blood, that more was obtained from the young than from the old animals.

3. A third circumſtance which varies the alkaleſcency of the food, is the wildneſs or tameneſs of the animal; and this again ſeems to depend on its exerciſe. We knew a gentleman who was fond of cats for food: but he always uſed to feed them on vegetable food, and kept them from exerciſe; and in the ſame manner did the Romans rear up their rats, when intended for food. In the ſame way the fleſh of the partridge and the hen ſeems to be much the ſame; only, from its being more on the wing, the one is more alkaleſcent than the other. Again, tame animals are commonly uſed without their blood; whereas the wild are commonly killed in their blood, and upon that account, as well as their greater exerciſe, are more alkaleſcent.

4. The alkaleſcency of food may be determined from the quantity of volatile ſalt it affords. The older the meat is, it is found to give the greater proportion of volatile ſalt.

5. The alkaleſcency of aliment may alſo, in ſome meaſure, be determined from its colour, the younger animals being whiter and leſs alkaleſcent. We alſo take a mark from the colour of the gravy poured out, according to the redneſs of the juices, judging of the animals alkaleſcency.

6. The reliſh of food is found to depend much on its alkaleſcency, as does alſo the ſtimulus it gives, and the fever it produces in the ſyſtem. Theſe effects are alſo complicated with the viſcidity of the food, by which means it is longer detained in the ſtomach and the want of alkaleſcency ſupplied. Having mentioned animal food as differing in ſolubility and alkaleſcency, which often go together in the ſame ſubject, we come to the third difference viz.

III. *Quantity of Nutriment.*

Which is either abſolute or relative: abſolute with reſpect to the quantity it really contains, ſufficient powers being given to extract it; relative, with reſpect to the aſſimilatory powers of thoſe who uſe it. The abſolute nutriment is of ſome conſequence; but the relative, in the robuſt and healthy, and except in caſes of extraordinary weakneſs, may, without much inconvenience, be diſregarded. In another caſe is the quantity of nouriſhment relative, viz. with regard to its perſpirability; for if the food is ſoon carried off by the excretions, it is the ſame thing as if it contained a leſs proportion of nouriſhment. For giving more fluid, that which is longer retained affords moſt; and, for the repair of the ſolids, that attention alſo is of advantage. Now gelatinous ſubſtances are long retained; and are, beſides, animal ſubſtances themſelves, diſſolved: ſo that, both abſolutely and relatively, ſuch ſubſtances are nutritious. Of this kind are eggs, ſhell-fiſh, &c. In adults, though it is diſputed whether their ſolids need any repair, yet, at any rate, at this period, fluid is more required; for this purpoſe the alkaleſcent foods are moſt proper, being moſt eaſily diſſolved. They are at the ſame time, the moſt perſpirable; on one hand that alkaleſcency leading to diſeaſe, while on the other their perſpirability obviates it. Adults, therefore, as writers juſtly obſerve, are better nouriſhed on the alkaleſcent; the young and growing, on gelatinous foods. All this leads to a compariſon of young and old meats; the firſt being more gelatinous, and the laſt more alkaleſcent. This, however, by experience, is not yet properly aſcertained. Mr. Geoffroy is the only perſon who has been taken up with the analyſis of foods. See *Memoirs de l' Academie*, l' an 1731 & 1732. His attempt was certainly laudable, and in ſome reſpects uſefully performed; but, in general, his experiments were not ſufficiently repeated, nor are, indeed, ſufficiently accurate. He has not been on his guard againſt the various circumſtances which affect meats; the cow kind liking a moiſt ſucculent herbage, which is not to be got in warm climates; while the ſheep are fond of a dry food, and thrive beſt there. Again, ſome of his experiments ſeem contradictory. He ſays, that veal gives more ſolution than beef, while lamb gives leſs than mutton, which is much to be doubted. If both he and Sanctorius had examined the Engliſh beef, the reſult, probably, would have been very different as to its perſpirability, &c. Beſides, Mr. Geoffroy has only analyſed beef and veal when raw; has made no proper circumſtantial compariſons between quadrupeds and birds; and has examined theſe laſt along with their bones, and not their muſcles, &c. by themſelves, as he ought to have done, &c. If a ſet of experiments of this kind were properly and accurately performed, they might be of great uſe; but, at preſent, for the purpoſe of determining our preſent ſubject, we muſt have recourſe to our alkaleſcency ſolubility, &c.

IV. *The Fourth Difference of Animal Food, is the Nature of the Fluids they afford.*

The whole of this will be underſtood, from what has been ſaid on alkaleſcency; the fluid produced being more or leſs denſe and ſtimulating, in proportion as that prevails.

V. *The Fifth Difference of Animal Foods is with Reſpect to their Perſpirability.*

The ſum of what can be ſaid on this matter is this, that ſuch foods as promote an acumulation of fluid in our veſſels, and diſpoſe to plethora, are the leaſt perſpirable, and commonly give moſt ſtrength; that the more alkaleſcent foods are the moſt perſpirable, though the viſcid and leſs alkaleſcent may attain the ſame property by long retention in the ſyſtem. The authors thers on perſpirability have determined the perſpiration of foods as imperfectly as Mr. Geoffroy has done the ſolubility, and in a few caſes only. We muſt not lay hold on what Sanctorius has ſaid on the perſpirability of mutton, becauſe he has not examined, in the ſame way, other meats in their perfect ſtate; far leſs on what Keil ſays of oyſters, as he himſelf was a valetudinarian, and conſequently an unfit ſubject for ſuch experiments, and probably of a peculiar temperament. As to the effects of Food on the Mind, we have already hinted at them above. It is plain, that delicacy of feeling, livelineſs of imagination, quickneſs of apprehenſion, and acuteneſs of judgment, more frequently accompany a weak ſtate of the body. True it is, indeed, that the ſame ſtate is liable to timidity, fluctuation, and doubt; while the ſtrong have that ſteadineſs of judgment, and firmneſs of purpoſe, which are proper for the higher and more active ſcenes of life. The moſt valuable ſtate of the mind, however, appears to reſide in ſomewhat leſs firmneſs and vigour of body. Vegetable aliment, as never overdiſtending the veſſels or loading the ſyſtem, never interrupts the ſtronger motions of the mind; while the heat, fulneſs, and weight, of animal food, are an enemy to its vigorous efforts. Temperance, then, does not ſo much conſiſt in the quantity, for that always will be regulated by our appetite, as in the quality, viz. a large proportion of vegetable aliment.

Food *of Plants*. See Syſtem of AGRICULTURE.

FOP, is uſed to denote a perſon who cultivates a regard to adventitious ornament and beauty to exceſs.

FORAMEN, in anatomy, a name given to ſeveral apertures or perforations in divers parts of the body; as, the external and internal foramina of the cranium or ſkull. The foramina in the upper and lower jaw. Foramen lachrymale. Foramen membranæ tympani.

Foramen *Ovale*, an oval aperture or paſſage through the heart of a fœtus, which cloſes up after birth. It ariſes above the coronal vein, near the right auricle, and paſſes directly into the left auricle of the heart, ſerving for the circulation of the blood in the fœtus, till ſuch time as the infant breathes, and the lungs are open; it being generally reckoned one of the temporary parts of the fœtus, wherein it differs from an adult; although almoſt all anatomiſts, Mr. Cheſelden excepted, aſſure us, that the foramen ovale has ſometimes been found open in adults. See FOETUS.

FORCE, in mechanics, denotes the cauſe of the change in the ſtate of a body when, being at reſt, it begins to move, or has a motion, which is either not uniform or not direct. See Syſtem of MECHANICS.

Force, in law, ſignifies any unlawful violence offered to things or perſons, and is divided into ſimple and compound. *Simple force*, is what is ſo committed, that it has no other crime attending it; as where a perſon by force enters on another's poſſeſſion, without committing any other unlawful act. *Compound force*, is where ſome other violence is committed with ſuch an act which of itſelf alone is criminal: as if one enters by force into another's houſe, and there kills a perſon or raviſhes a woman. There is likewiſe a force implied in law, as in every treſpaſs, reſcue, or diſſeiſin, and an actual force with weapons, number of perſons, &c. Any perſon may lawfully enter a tavern, inn, or victualling-houſe; ſo may a landlord his tenant's houſe to view repairs, &c. But if, in theſe caſes, the perſon that enters commits any violence or force, the law will intend that he entered for that purpoſe.

Force is alſo divided into *true force*, or *force after a ſort*. There are other branches; as forcible entries, forcible detaining, or holding unlawful aſſemblies, routes, riots, rebellions, &c.

Force, in grammar, and ſome other arts, is applied to a thing which ſtands in lieu of, or has the ſame effect, as another. In our language, the ſ between two vowels has the force or power of a *z*, and is ſometimes put for a *z*; as in horiſon, baptiſing, &c. In Hebrew, the *dageſh*; and in Arabic, the *teſdid*; have the force of a letter ſuppreſſed. An unit before a cypher, has the force of ten.

FORCEPS, a ſurgeon's inſtrument, wherewith dead and corrupt parts are ſeized, cut, or pulled off, &c. As alſo foreign bodies extracted out of wounds, &c. The word literally denotes a pair of tongs. They are of divers forms: long, crooked, with teeth, with beaks, half-mooned, &c. The forceps is alſo uſed for extracting the fœtus in caſes of preternatural delivery. The inſtrument uſed for this purpoſe is either ſtrait or curved. The ſtrait forceps is uſed for bringing the head of the child forward, when on account of its ſize, or the want of pains, it cannot otherwiſe be protruded; but the uſe of them requires great care; and it is obſerved, that inſtruments of this kind are never neceſſary, whilſt the head is above the brim of the pelvis, and rarely when it hath deſcended lower. Dr. Hunter abſolutely forbids the uſe of them, if they can poſſibly be avoided. Thoſe improved by Smellie are the beſt, who has reduced their length, in order to prevent their being uſed before the head is low enough. The long curved forceps was invented by Smellie, with a view of ſaving the life of the child, when the body being delivered, the head could not be brought away in the uſual manner. Theſe are longer than the ſtrait ones, becauſe they are applied, when the head of the child is above the brim of the pelvis. The ſtrait and curved forceps, as well as the blunt hook, are uſed to expedite and facilitate delivery; whereas the crotchet, which has a hook at its point that is forced into the part to which it is applied, wounds, and generally kills the child. See Syſtem of MIDWIFERY.

FORCER, in mechanics, is properly a piſton, without a valve. There are ſeveral ways of making forcers; the moſt common of all conſiſts of a braſs cylinder, a very little leſs in diameter, at its bottom and top, than the bore of the barrel of the pump, and turned ſtill leſs at the middle, in order to let in a leathern ring or collar (made of a thick leather put round the braſs cylinder,) which makes it juſt equal to the bore of the barrel, ſo as to fit it quite when it is put into it.

FORCIBLE *Entry*, a violent, actual entry into houſes, or lands, &c. with menaces or weapons, whether violence or hurt be offered to any perſon therein, or not.

Forcible *Holding*, or *detaining*, a with-holding by violence, and with a ſtrong hand, of the poſſeſſion of land, &c. whereby he who has a lawful right of entry is barred or hindered. This was formerly allowable to every perſon diſſeiſed, or turned out of poſſeſſion, unleſs his entry was taken away or barred by his own neglect, or other circumſtances. But being found very prejudicial to the public peace, it was thought neceſſary, by ſeveral ſtatutes, to reſtrain all perſons from the uſe of ſuch violent methods even of doing themſelves juſtice: ſo that the entry now allowed by law is a peaceable one.

Forcible *Abduction*, and *Marriage*, vulgarly called ſtealing an heireſs. By ſtat. 3 Hen. VII. cap. 2. it is enacted, that if any perſon ſhall, for lucre, take any woman, maid, widow, or wife, having ſubſtance either in goods or lands, or being heir apparent to her anceſtors, contrary to her will, and afterwards ſhe be married to ſuch miſdoer, or by his conſent to others, or defiled; ſuch perſon, and all his acceſſaries, ſhall be deemed principal felons: and by ſtat. 39 Eliz. cap. 9. the benefit of clergy is taken away from all ſuch felons, except acceſſaries after the offence. See MARRIAGE.

FORCING, in the wine trade, a term uſed by the wine coopers for the fining down wines, and rendering them fit for immediate draught.

Forcing, among gardeners, is uſed for producing ripe fruits from trees before their natural ſeaſon. The method of doing it is this: a wall ſhould be erected ten foot high; a border muſt be marked out on the ſouth ſide of it, of about four foot wide, and ſome ſtakes muſt be faſtened into the ground all along the edge of the border; theſe ſhould be four inches thick. They are intended to reſt the glaſs-lights upon, which are to ſlope backwards to the wall, to ſhelter the fruit as there ſhall be occaſion; and there muſt be at each end a door to open either way, according as the wind blows. The frame ſhould be made moveable along the wall, that when a tree has been forced one year, the frame may be removed to another, and ſo on, that the trees may be each of them forced only once in three years, at which rate they will laſt a long time. They muſt be always well-grown trees that are choſen for forcing, for young ones are ſoon deſtroyed, and the fruit that is produced from them is never ſo well taſted. The fruits moſt proper for this management are the avant, or ſmall white nutmeg, the albermarle, the early Newington, and the brown nutmeg peaches; Mr. Fairchild's early, and the elrugo and Newington nectarins; the maſculine apricot, and the May-duke and May-cherry. For grapes, the white and black ſweet-water are the moſt proper; and of gooſeberries, the Dutch white, the Dutch early green, and the walnut gooſeberry; the large Dutch white, and large Dutch red currants. The dung, before it is put to the wall, ſhould be laid together on a heap for five or ſix days, that it may heat uniformly through; and when thus prepared, it muſt be laid four foot thick at the baſe of the wall, and go ſloping up, till it is two foot thick at the top. It muſt be laid at leaſt within three or four inches of the top of the wall, and when it ſinks, as it will ſink two or three feet, freſh dung muſt be laid; for the firſt heat will do little more than juſt ſwell the bloſſom-buds. The covering of the trees with glaſſes is of great ſervice, but they ſhould be taken off to admit the benefit of gentle ſhowers to the trees.

FORE, applied to a ſhip, denotes all that part of a ſhip's frame and machinery which lies near the ſtem.

Fore and *Aft* is uſed for the whole ſhip's length, or from end to end.

Fore *Caſtle of a Ship*, is a ſhort deck placed in the fore part of the ſhip, above the upper deck.

FORECLOSED, in our ancient law books, ſignifies barred, ſhut out, or excluded for ever: as, when the equity of redemption on MORTGAGES is barred.

FOREIGN, ſomething extraneous, or that comes from abroad.

Foreign in the Engliſh law, is uſed in various ſignifications. Thus, Foreign attachment, is an attachment of the goods of foreigners found within a city or liberty, for the ſatisfaction of ſome citizen to whom the foreigner is indebted; or it ſignifies an attachment of a foreigner's money in the hands of another perſon. Foreign kingdom, a kingdom under the dominion of a foreign prince. At the inſtance of an ambaſſador or conſul, an offender againſt the laws here may be ſent for hither from a foreign kingdom to which he hath fled. And, where a ſtranger of Holland, or any foreign country, buys goods at London, for inſtance, and then goes away privately into Holland; in that caſe, the ſeller may have a certificate from the lord mayor, on the proof of the ſale and delivery of ſuch goods, whereupon a proceſs will be executed on the party in Holland. Foreign ſeamen, ſerving two years on board Britiſh ſhips, whether of war, trade, or privateers, during the time of war, ſhall be deemed natural born ſubjects.

FOREIGNER, the natural born ſubject to ſome foreign prince. Foreigners, though made denizens, or naturalized, are diſabled to bear any office in government, to be of the privy council, or members of parliament, &c. This is by the acts of the ſettlement of the crown. Such perſons as are not freemen of a city or corporation, are alſo called foreigners, to diſtinguiſh them from the members of the ſame.

FOREIGNERS reſiding ſeven years in the Britiſh plantations, without any longer abſence than two months at one time, and taking the oaths, are to be deemed natural born ſubjects. But, excepting quakers and Jews, all other perſons muſt receive the ſacrament in ſome proteſtant or reformed congregation in Great Britain, or the colonies; a certificate whereof muſt be produced at the time of taking the oaths. 13 Geo. II. cap. 7 ſect. 2. See NATURALIZATION.

FOREJUDGER, in law, ſignifies a judgment whereby one is deprived, or put by a thing in queſtion. To be forejudged the court, is where an officer or attorney of any court is expelled the ſame for mal-practice, or for not appearing to an action on a bill filed againſt him, &c. And where an attorney of the common-pleas is ſued, the plaintiff's attorney delivers the bill to one of the criers of the court, who calls the attorney defendant, and ſolemnly proclaims aloud, that, if he does not appear thereto, he will be forejudged: likewiſe a rule is given by the ſecondary for his appearance: and if the attorney appears not in four days, then the clerk of the warrants ſtrikes ſuch an attorney off the roll of attorneys; after which he becomes liable to be arreſted like any other perſon: but where an attorney is forejudged, he may be reſtored on clearing himſelf from his contumacy, and making ſatisfaction to the plaintiff, &c.

FOREJUDGED *the Court*, is when an officer of any court is baniſhed, or expelled the ſame, for ſome offence; or for not appearing to an action by bill filed againſt him; in which latter caſe, he is not to be admitted to officiate, till he appear to the bill. Anno 2 Hen. IV. cap. 8.

FOREST, in geography, a large wood or great extent of ground covered with trees. The Caledonian and Hercynian foreſts are famous in hiſtory. The firſt was a celebrated retreat of the ancient Picts and Scots: the latter anciently poſſeſſed the greateſt part of Europe; particularly Germany, Poland, Hungary, &c. In Cæſar's time it extended from the borders of Alſatia and Switzerland to Tranſylvania, and was computed ſixty days journey long, and nine broad: ſome parts or cantons thereof are ſtill remaining. The foreſt of Dean in Glouceſterſhire, is famous for the iron works therein. The ancients adored foreſts, and imagined a great part of their gods to reſide therein: temples were frequently built in the thickeſt foreſts, the gloom and ſilence whereof naturally inſpired ſentiments of devotion, and turned men's thoughts within themſelves. For the like reaſon, the ancient Druids made foreſts the place of their reſidence, and performed their ſacrifices, inſtructed their youth, and gave laws therein. See DRUIDS.

FOREST, in a law ſenſe, is defined a certain territory of woody grounds and fruitful paſtures, privileged for wild beaſts and fowls of foreſt, chace, and warren, to reſt and abide in, under protection of the king, for his recreation and delight; bounded with unremoveable marks and meres, either known by matter of record or preſcription. The properties and characters of a foreſt are, firſt, that it cannot be in the hands of any but the king; becauſe none elſe had power to conſtitute ſuch commiſſions as are neceſſary to the being of a foreſt, beſide the king; as, particularly, that of juſtice in eyre of the foreſt. And yet the abbot of Whitby had a foreſt by grant of king Henry II. and king John, with all officers incident thereto. The ſecond character, is the courts belonging thereto, which are, the juſtice-ſeat, and the regard, held every third year; the ſwanimote, held thrice every year; and the attachment, once every forty days.

The third characteriſtic is the officers belonging thereto, for preſervation of the game as the juſtices of the foreſt, the warder or keeper, ranger, verderers, foreſters, agiſtors, regarders, bailiffs, beadles, &c. See each under its proper article, JUSTICE *of the foreſt*, KEEPER, &c.

New foreſt in Hampſhire, hiſtory tells us, was made by the deſtruction of twenty-two pariſh churches, and all the villages, manors, chapels, &c. for the ſpace of thirty miles together. Beſide New Foreſt, there are now ſubſiſting ſixty-eight foreſts in England, &c. thirteen chaces, the four principal foreſts are New-foreſt on the ſea, Shirewood-foreſt on the Trent, Dean-foreſt on the Severn, and Windſor-foreſt on the Thames.

A foreſt in the hands of a ſubject is properly the ſame thing with a chaſe; being ſubject to the common law, and not to the foreſt laws. But a chaſe differs from a foreſt, in that it is not incloſed; and likewiſe, that a man may have a chaſe in another man's ground as well as his own; being indeed the liberty of keeping beaſts of chaſe, or royal game therein, protected even from the owner of the land, with a power of hunting them thereon. See PARK.

Our ancient Norman kings were the firſt who incloſed foreſts; and ſettled the juriſdiction thereof. In the courſe of a few reigns from the Conqueſt, no leſs than ſixty-eight foreſts were incloſed; the ſtricteſt laws were made to ſecure them, and the ſevereſt penalties inflicted on all treſpaſſers thereon. William the Conqueror decreed the eyes of any perſon to be pulled out, who took either a buck or boar: William Rufus, made the ſtealing of a doe a hanging matter; the taking of a hare was fined 20s. and a coney at 10s. Eadmer adds, that fifty perſons of fortune, being apprehended by that laſt prince for killing his bucks, were forced to purge themſelves by the fire of ordeal, &c. Henry I. made no diſtinction between him who killed a man, and him who killed a buck; and puniſhed thoſe who deſtroyed the game, though not in the foreſt, either by forfeiture of their goods, or loſs of limbs; though Henry II. remitted it for a temporary impriſonment. Richard I. revived the old diſcipline of gelding and pulling out the eyes of thoſe convicted of hunting in the foreſt: but he afterwards relaxed a little, and was contented to make ſuch convicts abjure the realm, or be committed, or pay a fine.

FOREST *Law*. The foreſt laws are peculiar laws, different from the common law of England. Before the making of Charta de Foreſta, in the time of king John and his ſon Henry III. confirmed in parliament by 9 Henry III. offences committed therein were puniſhed at the pleaſure of the king, in the ſevereſt manner. By this charter, many foreſts were diſafforeſted and ſtripped of their oppreſſive privileges, and regulations were made for the government of thoſe that remained; particularly, killing the king's deer was made no longer a capital offence, but only puniſhed by fine, impriſonment, or abjuration of the realm: yet even in the charter there were ſome grievous articles, which the clemency of later princes have ſince by ſtatute thought fit to alter *per aſſiſas* foreſtæ.

FOREST *Trees*. Many are wholly averſe to pruning foreſt trees; but though it is to be done with care, and under proper regulations (ſee LOPPING), yet it is by no means to be wholly omitted. It may be obſerved in foreſts and large woods, that for one tree which thrives well, there are twenty that grow faulty, and all this is owing to the want of pruning or lopping in a proper manner, for this, when wiſely executed, is a renewal of their age, and of their growth too; the want of it being what occaſions trees to run out into ſuckers, and to load themſelves with uſeleſs boughs, which draw away the ſap from the upper part, and make it grow knotty and diſtempered, and uſually covered with moſs.

FORE *Staff*, an inſtrument uſed at ſea, for taking the altitude of heavenly bodies. The fore ſtaff, called alſo croſs ſtaff, takes its denomination hence, that the obſerver, in uſing it, turns his face towards the object, in contradiſtinction to the back ſtaffs where he turns his back to the object.

FORESTALLING, the buying or bargaining for corn, cattle, or other merchandize, by the way, before it reaches the market or fair, to be ſold; or by the way, as it comes beyond the ſeas, or otherwiſe, toward any city, port, haven, or creek, of this realm, with deſign to take advantage thereof, and ſell it again at a more advanced and dear rate. By the 5th and 6th Edw. VI. cap. 14. any buying or contracting for merchandize, victuals, or other things whatſoever, in the way, coming by land or water to any fair or market, or to any port, &c. to be ſold, or cauſing the ſame to be bought; or diſſuading people by word, letter, or meſſage, or otherwiſe, from bringing ſuch things to market; or perſuading them to enhance the price after they are brought thither; is foreſtalling: and the party guilty of any offence of foreſtalling, &c. upon conviction at the quarter-ſeſſions by two witneſſes, on bill, information, preſentment, &c. ſhall, for the firſt offence, loſe the goods ſo bought, or the value of them, and ſuffer two months impriſonment; for the ſecond offence, he ſhall forfeit double the value, and be impriſoned ſix months; and for the third offence, he ſhall loſe all his goods, be ſet up in the pillory, and be impriſoned at the king's pleaſure.

FORFEITURE, originally ſignifies a tranſgreſſion or offence againſt ſome penal law. But the word is now frequently uſed for the effect of ſuch tranſgreſſion, or the loſing ſome right, privilege, eſtate, honour, office, or effects, in conſequence thereof than for the tranſgreſſion itſelf; as forfeiture of eſcheats, forfeiture of goods, &c. A fee becomes vacant by the forfeiture or rebellion of the vaſſal.

Goods forfeited, and goods confiſcated, differ: thoſe which have a known owner, who has committed ſome offence, whereby he loſes his goods, are ſaid to be forfeited: thoſe which an offender diſavows, as not his own, and which are not claimed by any other, are ſaid to be confiſcated, ſtat. 25 Edw. III. Add, that forfeiture, or forfeit, is more general; and confiſcation more particular, being principally uſed for ſuch as forfeit only to the king's exchequer.

The true reaſon of any forfeiture for crimes, ſays judge Blackſtone, is this; that all property is derived from ſociety, being one of thoſe civil rights which are conferred upon individuals, in exchange for that degree of natural freedom, which every man muſt ſacrifice when he enters into ſocial communities; if, therefore, a member of any national community violates the fundamenta contract of his aſſociation, by tranſgreſſing the municipal law, he forfeits his right to ſuch privileges as he claims by that contract; and the ſtate may very juſtly reſume that portion of property, or any part of it, which the laws have before aſſigned him. Hence, in every offence of an atrocious kind, the laws of England have exacted a total confiſcation of the moveables or perſonal eſtate; and in many caſes a perpetual, in others only a temporary loſs of the offender's immoveables or landed property; and have veſted them both in the king, who is the perſon ſuppoſed to be offended, being the one viſible magiſtrate in whom the majeſty of the public reſides. Blackſt. Com. vol. i. p. 299.

FORFICULA, the ear-wig, in entomology, a genus of inſects belonging to the order of coleoptera. The antennæ are briſtly; the elytra are dimidiated; the wings are covered; and the tail is forked. There are two ſpecies, viz. the auriculata, or common ear-wig, with the tops of the elytra white; and the minor, with teſtaceous and unſpotted elytra. It is a very troubleſome creature, frequently introducing itſelf into the ears, and cauſing a great deal of pain by its biting: it likewiſe burrows in other parts of the body; which it bites in the ſame manner. For the claſſification, ſee ſyſtem of ENTOMOLOGY.

Ear-wigs are very miſchievous vermin in gardens, eſpecially where carnations are preſerved; for they are ſo fond of theſe flowers, that, if care is not taken to prevent them, they will entirely deſtroy them, by eating off the ſweet part at the bottom of the petals or leaves. To prevent this, moſt people have ſtands erected, which have a baſon of earth or lead round each ſupporter, which is conſtantly kept filled with water. Others hang the hollow claws of crabs and lobſters upon ſticks in divers parts of the garden, into which thoſe vermin get; and by often ſearching them, you will deſtroy them without much trouble, which will be of great ſervice to your wall fruit, for theſe are great deſtroyers alſo of all ſoft fruits.

FORGE properly ſignifies a littlefurnace, wherein ſmiths, and other artificers in iron or ſteel, &c. heat their metals red hot, in order to ſoften and render them more malleable and manageable on the anvil, &c. We ſay, a farrier's forge, ſilverſmith's forge, cutler's forge, lockſmith's forge, &c. The forge uſed by the ſeveral operators in iron is very ſimple; we ſhall inſtance in that of the blackſmith, to which all the reſt are reducible.

The hearth or fire place, is a maſs of brick, about two feet ſix inches high: the back of the forge is built upright to the cieling, and is incloſed over the fire place with a hovel, which leads into a chimney, to carry away the ſmoke. In the back of the forge, againſt the fire place, is a thick iron plate, with a taper pipe fixed therein, about five inches long, called the tewel, into which the noſe or pipe of the bellows is received: the uſe of this plate and tewel is, to preſerve the pipe of the bellows, and the back of the hearth, from being burnt. Right before the back, at about two feet diſtance, is the trough, filled with water, to wet the coals with, and thereby increaſe their force, as alſo to quench the iron in. Behind the back of the forge is placed the bellows, one of whoſe boards is fixed ſo, that it moves not, either upward or downward; and to the other is fitted [illegible]e, chain, or even a rod, which riſing perpendicularly, is fixed to a croſs piece, called the rocker, which moving on a kind of fulcrum near the middle, ſerves as a handle. By drawing down this handle, the moveable board of the bellows riſes, and, by a conſiderable weight at the top of its upper ſide, it ſinks down again, and, by this alternate agitation, performs the neceſſary motions of a pair of bellows. See BELLOWS.

Braziers and copperſmiths forge differs but little from that already deſcribed; only that it is much leſs, and that nothing is burnt in it but charcoal, the metals uſed by theſe operators not working well with pit-coal. Forge is alſo uſed for a large furnace, wherein iron ore, taken out of the mine, is melted down. But this is not ſo properly called a forge as a furnace.

FORGE is more properly uſed for another kind of furnace wherein the iron ore, melted down and ſeparated in a former furnace, and there caſt into ſows and pigs, is heated; and fuſed over again, and beaten afterwards with large hammers, and thus rendered more ſoft, pure, ductile, and fit for uſe. Of theſe forges there are two kinds, which the iron ſucceſſively paſſes through, before it comes to the ſmith. The firſt is called the finery, where the pigs are worked into groſs iron, and prepared for the ſecond, which is called the chafery, where it is farther wrought into bars fit for uſe.

FORGE, *Travelling*, in the train of artillery, is a kind of portable ſmith's ſhop, by means of which any neceſſary work may be performed on a march, as well as in camp. This kind of forge has been formerly fixed in a carriage with two wheels, and wooden ſupporters, to prop the forge when uſed: but they are now commonly made with four wheels, ſo that they ſtand more firmly, and are more eaſily removed.

FORGE *for Red-hot Balls*, is a place where the balls are made red hot before they are fired off: it is conſtructed about five or ſix feet below the ſurface of the ground, of ſtrong brick-work, and an iron grate upon which the balls are laid with a large fire under them.

FORGERY, in law, is where a perſon fraudulently make and publiſhes falſe writings, to the prejudice of another man's right: and forgery is either at common law, or by ſtatute, puniſhable by indictment, information, &c. But there can be no forgery where no one can be prejudiced by it, but the perſon doing it. 1 Salk. 375. Forgery, by common law, extends to a falſe and fraudulent making or altering of a deed or writing, whether it be matter of record, or any other writing, deed, or will. 3 Inſt 169. 1 Roll. abr. 65. Not only where a falſe deed is made, but where a fraudulent alteration is made of a true deed in a material part of it, it is forgery. By a late act, an offender forging or counterfeiting any deed, will, bond, bill of exchange, note, or acquittance for money, or any indorſement or aſſigment of a bill, &c. with intent to defraud any perſon, or publiſhing ſuch falſe deed, &c. to be true, knowingly, ſhall be guilty of felony, and ſuffer death as a felon; but not to work any corruption of blood, &c. Stat. 2 Geo. II. cap. 25. 7 Geo. II. cap. 22.

By an act paſſed in 1778, explaining the former laws on the ſubject of forgeries, it is enacted, that making or forging, &c. or cauſing to be made or forged, &c. or aſſiſting in making or forgeing, &c. any acceptance of any bill of exchange, or the number or principal ſum of any accountable receipt for any note or bill, or any warrant or order for payment of money or delivery of goods, with intention to defraud any corporation, or publiſhing as true any ſuch forged acceptance, &c. incur the guilt of felony, and the puniſhment of death, without benefit of clergy, 18 Geo. III.

FORGING, in the mechanic arts, the act of beating or hammering iron on an anvil, after having firſt made it red-hot in the forge in order to extend it into various forms, and faſhion it into works. Iron is hammered and forged two ways; either by the force of the hand, in which there are uſually ſeveral perſons employed, one of them turning the iron, and hammering likewiſe, and the reſt only hammering. Or, it is done by the force of a water mill, which raiſes and works ſeveral huge hammers, beyond the force of man, under the ſtrokes whereof the workmen preſent large lumps or peices of iron, which are ſuſtained, at one end, by the anvils, and, at the other, by iron chains faſtened to the ceiling of the forge. This laſt way of forging is only uſed in the largeſt works, as anchors for ſhips, &c. which uſually weigh ſeveral thouſand pounds. For the lighter works, a ſingle man ſuffices to hold, heat, and turn, with one hand, while he ſtrikes with the other. Each purpoſe for which the work is deſigned, requires its proper heat. If it be too cold it will not feel the weight of the hammer, as the ſmiths call it, i. e. it will not ſtretch or give way; and, if it be too hot, it will red-ſear, i. e. it will break or crackle under the hammer. The ſeveral heats the ſmiths give to their irons are. 1. A blood-red heat. 2. A white-flame heat. 3. A ſparkling or welding heat.

FORM, in phyſics, the eſſential or diſtinguiſhing modification of the matter whereof a natural body is compoſed, ſo as thereby to give it ſuch a particular manner of exiſtence; being that which conſtitutes it ſuch a particular body, and diſtinguiſhes it from every other body.

FORM is alſo uſed, in a moral ſenſe, for the manner of being or doing a thing according to rules: thus we ſay, a form of government, a form of argument, &c.

FORM, in law, the rules eſtabliſhed and requiſite to be obſerved in legal proceedings. The formal part of the law, or method of proceeding, cannot be altered but by parliament; for if once theſe outworks were demoliſhed, there would be an inlet to all manner of innovation in the body of the law itſelf.

FORM, in carpentry, is uſed to denote the long ſeats or benches in the choirs of churches or in ſchools, for the prieſts, prebends, religious, or ſcholars, to ſit on. At ſchools, the word form is frequently applied to what is otherwiſe termed a claſs. See CLASS.

FORM alſo denotes the external appearance or ſurface of a body, or the diſpoſition of its parts, as to the length, breadth, and thickneſs.

FORM is alſo uſed, among mechanics, for a ſort of mould whereon any thing is faſhioned or wrought.

Printer's FORM, an aſſemblage of letters, words, and lines, ranged in order, and ſo diſpoſed into pages by the compoſitor; from which by means of ink and a preſs, the printed ſheets are drawn. Every form is incloſed, in an iron chaſe, wherein it is firmly locked by a number of pieces of wood: ſome long and narrow, and others of the form of wedges. There are two forms required for every ſheet, one for each ſide; and each form conſiſts of more or fewer pages, according to the ſize of the book.

Hatter's FORM, is a large block or piece of wood, of a cylindrical figure; the top thereof rounded, and the bottom quite flat. Its uſe is, to mould or faſhion the crown of the hat, after the matter thereof has been beaten and fulled.

Paper-maker's FORM, is the frame or mould wherein the ſheets are faſhioned. See PAPER.

FORMA *Pauperis*, or *in* FORMA *Pauperis*, is when a perſon has a cauſe or ſuit, but is ſo poor that he cannot defray the uſual charges of ſuing at law, or in equity. In this caſe, upon his making oath that he is not worth 5l. his debts being paid, and bringing his certificate from ſome lawyer, that he has juſt cauſe of ſuit, the judge admits him to ſue *in forma pauperis*; that is without paying fees to the councellor, attorney, or clerk. This cuſtom has its beginning from ſtat. 11 Hen. VII. cap. 12.

FORMAL, ſomething that regards the form; or that gives the manner, or form.

The formal cauſe joining itſelf to the material, produces the body or compound. The ſchoolmen alſo apply the word to any thing which has a kind of form, either eſſential or accidental, at leaſt, in our conception. Thus we frequently hear the philoſophers talk of the formal object of knowledge; and of the formal reaſon of any thing; formal unity, &c. Formal cauſe is defined, by certain philoſophers, to be ſomething implanted in one parcel of matter, whereby it is diſtinguiſhed from all other matter. For matter is ſuppoſed common to all bodies: conſequently, that they are diſtinguiſhable from one another, does not ariſe from their matter, but from the form which is peculiar to each: hence, what is produced by ſuch cauſe, is ſaid to be formal. Hence it follows, that the cauſalty of matter and form is not the ſame: or that the component power and the actual compoſition, are different; contrary to the opinion of the generality of ſchoolmen, who, maintaining form to be a ſubſtance co-extended with matter, make it a real component part, as much as matter itſelf.

FORMAL is alſo uſed in a moral ſenſe, importing poſitive, expreſs, and preciſe. Thus we ſay, a formal agreement, a formal text, formal anſwer, &c. Formal evidence.

FORMALITIES, in matters of law, are frequently uſed for the formulas themſelves, or the rules preſcribed for judiciary proceedings. In contracts of ſtrict law, all the formalities muſt be ſtrictly obſerved: an omiſſion of the leaſt formality may ruin the whole convention. The term is alſo uſed for a certain order, or decorum, to be obſerved.

FORMATION, in philoſophy, &c. the act of forming, faſhioning, or producing a thing.

FORME', or FORMY, in heraldry. A croſs formé, or formy, is a croſs narrow in the centry, and broad at the extremes.

FORMICA, or the ANT, in entomology, a genus of inſects belonging to the order of hymenoptera, the characters of which are theſe: There is a ſmall ſcale betwixt the breaſt and belly, and the joint is ſo deep, that the animal appears as if it were almoſt cut through the body. The females, and the neuters or working ants which have no ſexual characteriſtics, are furniſhed with a hidden ſting; and both the males and females have wings, but the neuters have none. There are 18 ſpecies, moſt of them diſtinguiſhed by their colours. Theſe inſects keep together in companies like bees, and maintain a ſort of republic. Their neſt is exactly ſquare, but longer one way than the other; and in it there are a ſort of paths, which lead to different magazines. Some of the ants are employed in making the ground firm, by mixing it with a ſort of glue, for fear it ſhould crumble and fall down upon their heads. They may be ſometimes ſeen to gather ſeveral twigs, which ſerve them for rafters, which they place over the paths, to ſupport the covering; they lay others acroſs them, and upon them ruſhes, weeds, and dried graſs, which they heap up into a double declivity, which ſerves to turn off the water from their magazines. Some of theſe ſerve to lay up their proviſions in, and in others they lay their eggs.

As for the proviſions, they lay up every thing that is fit for them to eat; and you may often ſee one loaded with pippin or grain of fruit, another with a dead fly, and ſeveral together with the carcaſe of a May-bug or other inſect. If they meet with any thing they cannot bring away, they eat it upon the ſpot, or at leaſt ſo much of it as may reduce it to a bulk ſmall enough for them to carry. They do not run about where they pleaſe, at all adventures: for ſome of them are ſent abroad to make diſcoveries; and if they bring back news that they have met with a pear, or a ſugar-loaf, or a pot of ſweet-meats, they will run from the bottom of the garden, as high as the third ſtory of a houſe, to come at it. They all follow each other in the ſame path, without wandering to the right or the left; but in the fields they are more at their liberty, and are allowed to run about in ſearch of game. There is a ſort of green fly, that does a great deal of miſchief among the flowers, and which curls up the leaves of peach and pear trees; and theſe are ſurrounded with a ſort of glue, or honey, which the ants hunt after very greedily; for they touch neither the plant nor the flies themſelves. Next to this, their greateſt paſſion is to lay up hoards of wheat, and other corn; and for fear the corn ſhould ſprout by the moiſture of the ſubterraneous cells, they gnaw off the end which would produce the blade. The ants are often ſeen puſhing along grains of wheat, or barley, much larger than themſelves.

In Africa, and particularly in Guinea, the ants are exceedingly troubleſome, and do a great deal of miſchief. They make their neſts of earth in the fields, twice as high as a man; beſides which they build large neſts in high trees, from which places they advance in ſuch prodigious ſwarms to their houſes, that they frequently oblige the inhabitants to quit their beds in the night-time. If you place a worm or a beetle where only one or two ants are, they will immediately depart, and bring with them above an hundred; after which they ſeize their prey, and march off with it in good order. Theſe ants are of various ſorts; ſome great, others ſmall; ſome black, and others red: the ſting of this laſt is very painful, and cauſes an inflammation. the white are as tranſparent as cryſtal, and have ſuch ſtrong teeth, that in a night's time they will eat their way through a thick wooden cheſt, and make it as full of holes as if it had been penetrated by hail-ſhot.

The ant lays eggs in the manner of the common flies, and from theſe eggs are hatched a ſort of ſmall maggots, or worms without legs: theſe are ſharp at one end, and blunt at the other; and are white, but ſo tranſparent, that the inteſtines are ſeen through the ſkin. Theſe, after a ſhort time, change into large white aureliæ, which are what are uſually called ants eggs. That end which is to be the tail is the largeſt, and that which is the head is ſomewhat tranſparent. The ants move theſe about at pleaſure with their forceps. It is well known, that when a neſt of theſe creatures is diſturbed, and the auraliæ ſcattered about, the ants are at infinite pains to get together all that are unhurt, and make a neſt for them again: nay, any ants will do this, and thoſe of one reſt will often take care of the aureliæ of another.

The affection of the ant for its offspring is amazing. They carry the young worms about in their mouths, that nothing may injure them; and when the earth of the neſt is dry, they carry them down to a greater depth, but when wet they bring them to the ſurface, that they may not be injured by the damps. The common ant builds only with ſmall pieces of dry earth, and there is always found a vaſt quantity either of eggs, worms, or aureliæ, at the bottom of the neſt. The aureliæ are covered only with a thin ſkin; and when carefully opened, they ſhew the worm perfect, and in its ſeveral ſtages of perfection.

The forecaſt of ants in providing againſt the winter is a miſtake. They are ſuppoſed not to eat in the winter, but to ſpend that ſeaſon, like dormice and many other ſorts of animals, in a ſtate of ſleep. What confirms this is, that they have been obſerved, as the cold draws on in the autumn, to move very heavily, and in the vintage-time they can hardly ſtir at all: ſo that the proviſion they make ſeems intended not for themſelves, but for their young. The care theſe creatures take of their offspring is remarkable. Whenever a hill is diſturbed, all the ants are buſied in conſulting the ſafety, not of themſelves, but of the eggs or theſe larger bodies incloſing the maggot or young ant; they carry theſe down any way ſo as to get them out of ſight, and will do this over and over as often as they are diſturbed. They carry away the eggs and vermicles together in their confuſion; but, as ſoon as the danger is over, they carefully ſeparate them, and place each ſort in parcels by themſelves under ſhelter of different kinds, and at various depths, according to the different degrees of warmth and coverture the different ſtates require. In the warm ſeaſon of the year, they every morning bring up the eggs, as they are uſually called, to the ſurface, or nearly ſo; and from ten in the forenoon to five in the afternoon or thereabouts, all theſe will be found juſt under the ſurface; and if the hills be examined toward eight in the evening, they will be found to have carried them all down; and if rainy weather be coming on, it will be neceſſary to dig a foot deep or more, in order to find them. Theſe little creatures are very troubleſome in gardens, and in paſture-lands; as well by feeding on the fruit, as by making up hills for their habitation. In the hotter countries, as Italy, Spain, and the Weſt Indies, ants are the greateſt peſt of [illegible]. Trees may be preſerved from them by encompaſſing the [illegible], for four fingers breadth, with a roll of wool, newly pulled from the ſheep's belly; or by laying ſaw-duſt all round the ſtump of it. Some anoint the tree with tar, which has the ſame effect. For the claſſification of this inſect. See Syſtem of ENTOMOLOGY, Genus LXI.

FORMICA *Leo*, the Ant lion, in entomology, an inſect ſo called from its devouring great numbers of ants. It is the caterpillar or worm of a fly much reſembling the libellæ or dragon-flies; and feeds chiefly upon ants, from which property it derives its name. It is ſomewhat of the nature of the ſpider in its way of taking its prey, its manner of ſpinning, and the figure and ſoftneſs of its body. It has, in its general figure, ſomewhat of the appearance of the millepes or wood-louſe, ſo that ſome have miſtaken it at firſt ſight for that animal. It is of a dirty greyiſh colour, marked with ſome black ſpots; and theſe are alſo compoſed of many points when viewed with a microſcope, which make it reſemble a hedgehog or porcupine. Its body is compoſed of ſeveral rings, and has thence a wrinkled look. It has ſix legs, four are joined to the breaſt, and the other two to a longer part, which may be taken for its neck. Its head is ſmall and flat, and it has two remarkable horns: theſe are about a ſixth part of an inch long, and as thick as a hair: they are hard, hollow, and hooked at the end like the claws of a cat. At the origin of each of theſe horns, it has a clear and bright black eye, which ſees very diſtinctly, and gives the creature notice to eſcape on ſight of the ſmalleſt object. This creature [illegible] not able to hunt after its prey, nor to deſtroy large inſects; [illegible] can only draw into its ſnares ſuch as come near its habitation, and of theſe very few are ſuch as he can manage: all the winged kind are able to eſcape by flight; and the beetle kinds, and others that have hard ſhells upon their bodies, are of no uſe to him, as his horns cannot pierce them. The ſmallneſs of the ant, and its want of wings, make it the deſtined prey of this devourer. The manner in which he catches his prey is as follows.

He uſually encamps under an old wall, that he may be ſheltered from the injuries of the weather; and he always chooſes a place where the ſoil is compoſed of a fine dry ſand. In this he makes a pit of the ſhape of a funnel, or an inverted hollow cone. If he intends the pit to be but ſmall, he thruſts down his hinder part into the ſand, and by degrees plunges himſelf backward into it; and when he has got to a certain depth, he toſſes out the looſe ſand which has run down with his head, artfully throwing it off beyond the edges of his pit. Thus he lies at the bottom of a ſmall hollow, which is wideſt at the top, and comes ſloping down to his body.

But if he is to make a larger pit, more pains are required to bring it to perfection. He firſt traces, in the ſurface of the ſand, a large circle, which is the erected baſe or mouth of the pit he is to make in form of an inverted cone. He then buries himſelf in the ſand near the edge of this circle, and carefully throws up the ſand above him, with his head toſſing it out beyond the circumference of the circle. Thus he continues his work, running down backwards in a ſpiral line all the way, and carefully throwing off the ſand from above him, till he is come to the place of his reſt, which is the point or reverted apex of the hollow cone he has formed by his paſſage. The length of his neck, and the flatneſs of his head, give him a power of uſing the whole as a ſpade, and throwing off the ſand with great eaſe; and his ſtrength in this part is ſo great, that he is able to throw off a quantity of it to ſix inches diſtance. This is a power he exerts oftener, however, in throwing away the remains of the animals he has fed upon, that his den may not become frightful to others of the ſame ſpecies, by ſeeing their fellow carcaſes about it.

When he has finiſhed his pit, he buries himſelf at the bottom of it among the ſand, leaving no part above ground but the tips of his two horns, which he expands to the two ſides of the pit. In this condition he lies and waits for his prey, and never comes up afterwards. When an ant, or any other ſuch creature, chances to walk over the edges of his pit, its ſteps throw down a little of the ſand, which naturally running down to the bottom of the pit, gives the enemy notice of his prey; he then toſſes up the ſand which covers his head, to bury the ant, and bring him down with its returning force to the bottom; and as one ſuch attempt cannot be ſufficient to prevent the ant's eſcape, he throws more and more ſand upon him, till he by degrees brings him down. All the endeavours of the ant to eſcape, when once it is within the verge of the pit, are in vain; for, as it attempts to climb, the ſand runs away from under its feet, and it ſinks the lower for every attempt.

This motion of the ſand alſo informs the enemy where it is, and directs him to throw up more ſand in the right place; which it does, till the poor ant falls to the bottom between its horns. It then plunges their points deep into the ant's body; and having ſucked out all the juice out of the prey, it throws out the empty ſkin as far from the hole as it can. This done, it mounts up the edges of its pit, and if it has ſuffered any injury, repairs it with great care, and immediately buries itſelf again in the centre, to wait for another meal. The horns of this creature are its only organs for receiving nouriſhment; it never brings any animal which it has ſeized near to its [illegible] but always holds it at the tip of the horns. They therefore only ſerve as ſyringes, to draw into its ſtomach the juices of the bodies of the inſects it feeds upon: neither is there any mouth or trunk, or any other organ to be diſcovered about its head, which could ſerve to the purpoſe of eating; the head ſeeming only intended for throwing away the ſand in forming the pit. The horns of this animal being ſo neceſſary to its life, nature has provided for the reſtoring them in caſe of accidents; and if cut off, they are found to grow again.

The food this creature procures by its pit can be but little; and as it has no power of catching its prey any other way, its motion being only backwards, and that ſlowly, and by ſmall ſpaces at a time, ſome people have believed its catching now and then an ant by this means was rather for diverſion than hunger. But though the formica leo will live a long time without food, and even paſs through all its changes, when ſhut up in a box, yet it always ready to eat when food is offered it; always appears ſtarved and ſmall when kept thus; and if a fly is given it in this hungry ſtate, it will ſo ſuck out all its juices, that the ſhell remaining may be rubbed to powder between the fingers, while the body of the creature that has ſucked it appears remarkably ſwelled and diſtended; ſo that it is plain that the juices of the prey are conveyed into the body of the creature; though it is not eaſy to ſee by what means, the horns not appearing to have any perforation.

When the formica leo has lived a proper time in this ſtate, it leaves its pit, and is only ſeen drawing lines and traces [illegible] the ſurface of the ſand. After this it buries itſelf under [illegible]; and there incloſes itſelf in a fine web, in which it is to [illegible] tranſformation into the winged ſtate.

When the creature has lain ſome time in this caſe, it [illegible] off its outer ſkin, with the eyes, the horns, and every other part neceſſary to its life before, and becomes an oblong nymph, which a careful eye may trace the form of the fly into which it is to be transformed. There may be ſeen, through its tranſparent covering, new eyes, new horns, wings, and all other parts of the animal in its perfect ſtate. This nymph makes its way about half out of the ſhell, and remains in this condition, but without farther life and motion, till the perfect fly makes its way out at a ſlit in the back. In this laſt ſtate it much reſembles the libellæ or dragon flies common about our waters. The male couples with the female in this ſtate only; and M. Poupart, to whom the world is obliged for this curious deſcription, is of opinion that the females lay only one egg; but this is very different from the courſe of nature in the other animals of the ſame claſs.

The common formica-leo moves only backward; but Mr Rouet has obſerved a ſpecies which moves forward in the common way of other animals, and makes no pit of this kind to entrap its prey, but ſeizes other inſects by force.

FORMING is uſed for the act of giving being or birth to any thing. The word is alſo ſimply uſed for giving the figure to any thing. The potter forms his veſſels as he pleaſes. Geometry teaches how to form all kinds of figures. It is alſo uſed for the producing of a thing: thus, the lineaments of the face began to be formed.

Forming *of a Siege*, is the making lines of circumvallation, to fortify the camp, and diſpoſing things for the attack of a place in form. They alſo ſay, to form a ſquadron or battalion; meaning to range the ſoldiers in form of a ſquadron, &c. The term is alſo uſed in ſpeaking of a body of forces, which being out of any order of ſquadrons, battalions, &c. do halt, range themſelves in order, and put themſelves in a condition for the attack. Forming the line, is drawing up infantry, cavalry, and artillery, into line of battle. See Line.

Forming is alſo uſed in grammar, in ſpeaking of certain tenſes of verbs, which are made from others, by a change of certain letters. The preſent tenſe is formed from the infinitive. Compound and derivative words alſo, and even all that have any etymology, are ſaid to be formed.

FORMULA, a rule, or model, or certain terms preſcribed and decreed by authority, for the form and manner of an act, inſtrument, proceeding, or the like.

FORMULARY, a writing, containing the form or formula of an oath, declaration, atteſtation, or abjuration, &c. to be made on certain occaſions. There are alſo formularies of devotion, of prayers, &c. Liturgies are formularies of the public ſervice in moſt churches.

FORNICATION, *Fornicatio*, from the *fornices* in Rome, where the lewd women proſtituted themſelves for money, is whoredom, or the act of incontinency, between ſingle perſons; for if either of the parties is married it is adultery. Formerly court-leets had power to enquire of and puniſh fornication and adultery; in which courts the king had a fine aſſeſſed on the offenders, as appears by the book of domeſday.

In the year 1650, when the ruling powers found it for their intereſt to put on the ſemblance of a very extraordinary ſtrictneſs and purity of morals, not only inceſt and wilful adultery were made capital crimes, but alſo the repeated act of keeping a brothel, or committing fornication, were, upon a ſecond conviction, made felony without benefit of clergy. But, at the reſtoration, when men, from an abhorrence of the hypocriſy of the late times, fell into a contrary extreme of licentiouſneſs, it was not thought proper to renew a law of ſuch unfaſhionable rigour. And theſe offences have been ever ſince left to the feeble-coercion of the ſpiritual court, according to the rules of the canon law; a law which has treated the offence of incontinence, nay, even adultery itſelf, with a great degree of tenderneſs and lenity; owing perhaps to the conſtrained celibacy of its firſt compilers. The temporal courts therefore take no cogniſance even of the crime of adultery otherwiſe than as a private injury.

FORRAGE, or Forage, proviſion for cattle, of hay, oats, and ſtraw; particularly in war. In marching, encamping, &c. care muſt be taken, that the cavalry may find forrage. A ratio of forrage is the portion of hay, ſtraw, and oats, allowed each horſeman, for the ſubſiſtence of his horſe one day; which is twenty pounds of hay, five of ſtraw, and ten pounds of oats.

Forrage *Guard*, in military affairs, a detachment ſent out to ſecure the forragers. The forrage guard is poſted at all places, where the enemies parties may come to diſturb the forragers. This guard is likewiſe called the covering party, and marches generally the night before the forraging, that they may be poſted in the morning before the forragers come. The guard conſiſts both of horſe and foot, and muſt ſtay at their poſt till the forragers be all come off the ground.

FORT, a little caſtle, or fortreſs; or a place of ſmall extent, fortified by art, or nature, or both. A fort is a work encompaſſed round with a moat, rampart, and parapet, to ſecure ſome high ground, or paſſage of a river; to make good an advantageous poſt; to fortify the lines and quarters of a ſiege.

FORTIFICATION, called alſo military architecture, is the art of fortifying or ſtrengthening a place, by making works around the ſame, ſuch as to render it capable of being defended by a ſmall force, againſt the attacks of a more numerous enemy.

SYSTEM OF FORTIFICATION.

WHEN villages and towns were firſt formed, it was found neceſſary, for the common ſafety, to encompaſs them with walls and ditches, in order to prevent all violence and ſudden ſurprizes from approaching enemies. When offenſive weapons were firſt invented, walls were made with loop-holes at proper diſtances in order to ſcreen the defenders againſt the arrows of the aſſailants; but finding, that as ſoon as the enemy got cloſe to the walls, they could from no part be diſcovered or repulſed, they added ſquare towers at proper diſtances from each other, ſo that every part of the wall might be defended by the adjacent ſides of the towers. But this manner of incloſing towns was found to be imperfect, becauſe there remained ſtill one of the faces of the towers which fronted the field, that could not be ſeen from any other part, and therefore could not be defended. To remedy this, they made the towers round inſtead of ſquare, imagining this figure to be the ſtrongeſt for reſiſting the battering engines, and likewiſe to be better defended from the other parts of the wall. Nevertheleſs part of theſe towers remained unſeen, and incapable of being defended, which made them change them again into ſquares as before; but, inſtead of preſenting a face to the field as formerly, they preſented an angle; and thus they obtained ſuch a diſpoſition of their works that no part could be attacked without being ſeen or defended by ſome other part.

The period, in which the modern practice of military architecture may be ſuppoſed to have taken its riſe, was that in which the old circular towers were firſt converted into baſtions, about the year 1500.

The firſt authors who have written of fortification, conſidered as a particular formed art, are La Treille, Alghiſi, Marchi, Paſino, Ramelli, Cataneo, and Speckle, who, as Mr. Robins ſays, was one of the greateſt geniuſes that has applied to this art. He was architect of the city of Straſburg, and died in the year 1589. He publiſhed a treatiſe of fortification in German, which was reprinted at Leipſic in 1736. Robins's Math. Tracts, vol. i. preface, p. 9. After them Errard, engineer to Henry the Great of France; Stevinus, engineer to the prince of Orange; Marolois, the chevalier de Ville, Lorini, Coehorn, the count de Pagan, and the marſhal de Vauban; which laſt two noble authors have contributed greatly to the perfection of the art. To whom we may add Scheiter, Mallet, Belidor, Blondel, Muller, &c.

From the idea and office of fortification may be drawn the following

Fundamental Axioms.

1. That the manner of fortifying ſhould be accommodated to that of attacking; ſo that no one manner can be aſſured always to hold, unleſs it be aſſured the manner of beſieging be incapable of being altered; and that to judge of the perfection of a fortification, the method of beſieging at the time when it was built muſt be conſidered. 2. All the parts of a fortification ſhould be able to reſiſt the moſt forcible machines uſed in beſieging, and they ſhould be equally ſtrong on all ſides. 3. A fortification ſhould be ſo contrived, as that it may be defended with as few men as poſſible; which conſideration, when well attended to, ſaves a vaſt deal of expence. 4. That the defendants may be in the better condition, they muſt not be expoſed to the enemy's guns and mortars; but the aggreſſors muſt be expoſed to theirs. 5. All the parts of a fortification ſhould be ſo diſpoſed as that they may defend each other: in order to which, every part muſt be flanked, ſo that there be no place where an enemy can lodge himſelf, either unſeen, or under ſhelter. 6. All the campaign around muſt lie open to the defendants; ſo that no hills or eminence muſt be allowed, behind which the enemy might ſhelter himſelf from the guns of the fortification; or from which he might annoy them with his own; wherefore the fortreſs, is to command all the place round about; conſequently the out-works muſt all be lower than the body of the place. 7. No line of defence is to be above point-blank muſket ſhot, which is from one hundred and twenty to one hundred and fifty fathom. 8. The acuter the angle at the centre, the ſtronger is the place; as conſiſting of the more ſides, and conſequently more defenſible. 9. All the defences ſhould be as nearly direct as poſſible. Such are the general laws and views of fortification.

Notwithſtanding all the improvements which have been made in the art of fortifying ſince the invention of gun-powder, that of attacking is ſtill ſuperior to it: engineers have tried in vain to render the advantages of a fortification equal to thoſe of the attack; the ſuperiority of the beſiegers fire, together with the greater number of men, obliges generally, ſooner or later, the beſieged to ſubmit. Fortification is either regular or irregular. Regular fortification, is that built in a regular polygon, the ſides and angles of which are all equal, being commonly about a muſket-ſhot from each other. Irregular fortification, on the contrary, is that where the ſides and angles are not uniform, equidiſtant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like.

SECT. I. OF REGULAR FORTIFICATION.

Although authors agree to the general form in the preſent manner of fortifying, yet they moſtly differ in particular conſtructions of the parts. As it would be both needleſs and ſuperfluous to treat of all the different methods hitherto propoſed, we ſhall content ourſelves with explaining thoſe only, which are moſt eſteemed by the beſt judges, and have been moſtly put in practice.

Conſtruction of M. Vauban's Method.

This method is divided into little, mean, and great, the little is chiefly uſed in the conſtruction of citadels, the mean in that of all ſorts of towns, and the great in particular caſes only. We ſhall give the conſtruction of the mean, as being moſt uſeful; and refer the reader to the table hereafter, for thoſe dimenſions which are different in theſe ſeveral fortifications. Inſcribe in a circle a polygon of as many ſides as the fortification is deſigned to have fronts; ſee *fig.* 1, plate II. let AB be one of the ſides of half an hexagon, which biſect by the perpendicular CD; divide half AC of it into nine equal parts, and one of theſe into ten others; then theſe diviſions will ſerve as a ſcale to conſtruct all the parts of the fortification, and each of them is ſuppoſed to be a toiſe or fathom, that is ſix French feet; and therefore the whole ſide AB is ſuppoſed to be 180 toiſes.

As the dividing a line into ſo many equal parts, is troubleſome and tedious; it is more convenient to have a ſcale of equal parts by which the works may be conſtructed. If therefore, in this caſe, the radius is taken equal to 180 toiſes, and the circle deſcribed with that radius being divided into ſix equal parts, or the radius being carried ſix times round, you will have an hexagon inſcribed; AB being biſected by the perpendicular CD as before, ſet off 30 toiſes from C to D, and draw the indefinite lines ADG, BDF; in which take the parts AE, BH, each equal to 50 toiſes; from the centre E deſcribe an arc through the point H, meeting AD in G, and from the centre H deſcribe an arc through the point E, meeting BD in F; or which is the ſame, make each of the lines EG, HF, equal to the diſtance EH; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front. If the ſame conſtruction be performed on the other ſides of the polygon, you will have the principal or outline of the whole fortification. If, with a radius of 20 toiſes, there be deſcribed circular arcs, from the angular points B, A, M, T, and lines are drawn from the oppoſite angles E, H, &c. ſo as to touch theſe arcs their parts *ab*, *bc*, &c. together with theſe arcs, will repreſent the outline of the ditch.

Definitions.

1. The part FEALN, is called the baſtion. 2. AE, AL, the faces of the baſtion. 3. EF, LN, the flanks. 4. FG, the curtain. 5. FN, the gorge of the baſtion. 6. AG, BF, the lines of defence. 7. AB, the exterior ſide of the polygon. 8. CD, the perpendicular. 9. Any line which divides a work into two equal parts, is called the capital of that work. 10. *abc*, the counterſcarp of the ditch. 11. A, M, the flanked angles. 12. H, E, L, the angles of the ſhoulder, or ſhoulder only. 13. G, F, N, the angles of the flank. 14. Any angle whoſe point turns from the place is called a ſaliant angle, ſuch as A, M; and any angle whoſe point turns towards the place, re-entering angle, ſuch as *b*, F, N. 15. If there be drawn two lines parallel to the principal or outline, the one at 3 toiſes diſtance, and the other at 8 from it; then the ſpace *y*X, included between the principal one and that fartheſt diſtant, is called the rampart. And the ſpace *x x*, contained by the principal line, and that near to it, and which is generally ſtained black, is called the parapet. 16. There is a fine line drawn within four feet of the parapet, which expreſſes a ſtep called banquette.

N. B. All works have a parapet of three toiſes thick, and a rampart of 8 or 10, beſides their ſlopes. The rampart is elevated more or leſs above the level of the place, from 10 to 20 feet, according to the nature of the ground and the particular conſtructions of engineers. The parapet is a part of the rampart elevated from 6 to 7 ½ feet above the reſt, in order to cover the troops which are drawn up there from the fire of the enemy in a ſiege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; ſo that when the troops ſtand upon it, they may juſt be able to fire over the parapet. 17. The body of the place, is all that which is contained within this firſt rampart: for which reaſon, it is often ſaid to conſtruct the body of the place; which means properly, the conſtruction of the baſtions and curtains. 18. All the works which are conſtructed beyond the ditch before the body of the place are called outworks.

TABLE.

	Forts.						Little Fortif.				Mean.		Great.	
Side of Polyg.	80	90	100	110	120	130	140	150	160	170	180	190	200	260
Perpendicul.	10	11	12½	14	15	16	20	21	23	25	30	31	25	22
Faces baſt.	22	25	28	30	33	35	40	42	45	47	50	53	55	60
Cap. of ravel.	25	28	30	35	38	40	45	50	50	52	55	55	60	50

In the firſt vertical column are the numbers expreſſing the lengths of the exterior ſides from 80 to 260. In the ſecond, the perpendiculars anſwering to theſe ſides. In the third, the lengths of the faces of baſtions; and in the fourth, the lengths of the capitals of the ravelins. The ſorts are moſtly, if not always, ſquares: for which reaſon, the perpendiculars are made one eighth of the exterior ſides; becauſe if they were more, the gorges of the baſtions would become too narrow. The little fortification is chiefly deſigned for citadels, and are commonly pentagons; the perpendiculars are made one ſeventh of the exterior ſide: the mean is uſed in all kinds of fortifications from an hexagon upwards to any number of ſides: and the great is ſeldom uſed but in an irregular fortification, where there are ſome ſides that cannot be made leſs without much expence; or in a town which lies near a great river, where the ſide next the river is made from 200 to 260 toiſes; and as that ſide is leſs expoſed to be attacked than any other, the perpendicular is made ſhorter, which ſaves much expence. The faces of the baſtions are all $\frac{2}{7}$ths of the exterior ſides, or nearly ſo, becauſe the fractions are neglected. It may be obſerved in general, that in all ſquares the perpendicular is $\frac{1}{8}$th of the exterior ſide, and all pentagons $\frac{1}{7}$th, and in all the reſt upwards $\frac{1}{6}$th.

1. *Conſtruction of Orillons and retired Flanks.*

Deſcribe the front MPQRST as before, and divide the flank into three equal parts, of which ſuppoſe S *r* to be one: from the oppoſite flanked angle M draw a line M *r*, in which take the part *m r* of 5 toiſes; take likewiſe R *n* in the line of defence M R, produced, equal to 5 toiſes, and join *n m*, upon which as a baſe deſcribe the equilateral triangle *n* P *m*, and from the angle P, oppoſite to the baſe as centre, is deſcribed the circular flank *n m*. And if S *r* be biſected by the perpendicular 1, 2, and another be erected upon the face S T, at S; the interſection 2 of theſe two perpendiculars, will be the centre of the arc which forms the oriſlon. The orillons are very uſeful, in covering the retired flanks, which cannot be ſeen but directly in the front; and as theſe orillons are round, they cannot be ſo eaſily deſtroyed as they would be if they were of any other figure.

2. *Conſtruction of Ravelins or Half-moons.*

Fig. 1. Plate I. Set off 55 toiſes, from the re-entering angle O of the counterſcarp, on the capital OL, or on the perpendicular produced, and from the point L draw lines to the ſhoulders A B; whoſe parts L M, L N, terminated by the counterſcarp, will be the faces, and MO, ON, the ſemi-gorges of the ravelin required. This is Mr. Vauban's method of conſtructing ravelins, according to ſome authors: and others will have the faces of the ravelin to terminate on thoſe of the baſtions within 3 toiſes of the ſhoulders; which ſeems to be the beſt way, for theſe ravelins cover the flanks much better than the others. The ditch before the ravelin is 12 toiſes, its counterſcarp parallel to the faces of the ravelins; and is made in a circular arc, before the ſaliant angle; as likewiſe all ditches are in general. When the ravelins are made with flanks, as in *fig.* 2, Plate I, the faces ſhould terminate on thoſe of the baſtions, at leaſt 5 toiſes from the ſhoulders. The flanks are made by ſetting off 10 toiſes from the extremities of the faces, from *f* to *h*, and from *m* to *l*; and from the points *h*, *l*, the flanks *h k*, *l p*, are drawn parallel to the capital L O of the ravelin. There are ſometimes redoubts made in the ravelin, ſuch as in *fig.* 1, Plate I. which is done by ſetting off 16 toiſes from the extremities of the faces on the ſemi-gorges from N to *b*, and from M to *a*; and from the points *b*, *a*, the faces are drawn parallel to thoſe of the ravelin: the ditch before the redoubt is 6 toiſes, and its counterſcarp parallel to the faces.

3. *Conſtruction of Tenailles.*

A tenaille is a work made in the ditch before the curtains, the parapet of which is only 2 or 3 feet higher than the level ground of the ravelin. There are three different ſorts: the firſt are thoſe as in *fig.* 3. Plate I. which are made in the direction of the lines of defence, leaving a paſſage of 3 toiſes between their extremities and the flanks of the baſtions, as likewiſe another of 2 in the middle for a bridge of communication to the ravelin.

The ſecond ſort are thoſe as in *fig.* 4. Plate I. Their faces are in the lines of defence, and 16 toiſes long, beſides the paſſage of 3 toiſes between them and the flanks of the baſtions; their flanks are found by deſcribing arcs from one ſhoulder of the tenaille as centre through the other, on which are ſet off 10 toiſes for the flanks deſired. The faces of the third ſort are 16 toiſes, as in the ſecond ſort, and the flanks are parallel to thoſe of the baſtions. The uſe in general of tenailles, is to defend the bottom of the ditch by a grazing fire, as likewiſe the level ground of the ravelin, and eſpecially the ditch before the redoubt within the ravelin, which can be defended from no where elſe ſo well as from them. The firſt ſort do not defend the ditch ſo well as the others, as being too oblique a defence; but as they are not ſubject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places, as may be ſeen in the citadel of Lille, at Laudau, New Briſac, and in a great many other places. The ſecond ſort defend the ditch much better than the firſt, and add a low flank to thoſe of the baſtions; but as theſe flanks are liable to be enfiladed, they have not been much put in practice. This defect might however be remedied, by making them ſo as to be covered by the extremities of the parapets of the oppoſite ravelins, or by ſome other work. As to the third ſort, they have the ſame advantage as the ſecond, and are likewiſe liable to the ſame objections: for which reaſon, they may be uſed with the ſame precautions which have been mentioned in the ſecond. Tenailles are eſteemed ſo neceſſary, that there is hardly any place fortified without them: and it is not without reaſon. For when the ditch is dry, the part behind the tenailles ſerves as a place of arms, from which the troops may ſally, deſtroy the works of the enemy in the ditch, oppoſe their deſcent, and retire with ſafety; and the communication from the body of the place to the ravelin becomes eaſy and ſecure: which is a great advantage; for by that means the ravelin may make a much better defence, as it can be ſupplied with troops and neceſſaries at any time. And if the ditch is wet, they ſerve as harbours for boats, which may carry out armed men to oppoſe the paſſage over the ditch whenever they pleaſe; and the communication from the tenailles to the ravelin, becomes likewiſe much eaſier than it would be without them.

4. *Conſtruction of Lunettes.*

Fig. 5. Plate I. Lunettes are placed on both ſides of the ravelin, ſuch as B, to increaſe the ſtrength of a place: they are conſtructed, by biſecting the faces of the ravelin with the perpendicular LN; on which is ſet off 30 toiſes from the counterſcarp of the ditch, for one of its faces; the other face, PN, is found by making the ſemi-gorge TP of 25 toiſes: the ditch before the lunettes is 12 toiſes, the parapet 3, and the rampart 8, as in the ravelin. There is ſometimes another work made to cover the ſaliant angle of the ravelin, ſuch as A, called *bonnet*, whoſe faces are parallel to thoſe of the ravelin, and when produced biſect thoſe of the lunettes; the ditch before it is 10 toiſes. There are likewiſe lunettes, whoſe faces are drawn perpendicular to thoſe of the ravelin, within a third part from the ſaliant angle; and their ſemi-gorges are only 20 toiſes. Theſe kind of works may make a good defence, and coſt no very great expence: for as they are ſo near the ravelin, the communication with it is very eaſy, and one cannot well be maintained till they are all three taken.

5. *Conſtruction of Tenaillons.*

Fig. 6. Plate I. Produce the faces of the ravelin beyond the counterſcarp of the ditch, at a diſtance MN of 30 toiſes, and take on the counterſcarp of the great ditch 15 toiſes from the re-entering angle *p* to *q*, and draw N *q*; then *q* NM *p* will be the tenailles required; its ditch is 12 toiſes, that is, the ſame as that of the ravelin. Sometimes there is made a retired battery in the front of the tenaillons, as in B; this battery is 10 toiſes from the front to which it is parallel, and 15 toiſes long. There are commonly retrenchments made in the tenaillons, ſuch as O; their parapets are parallel to the fronts MN, and biſect the ſide PN; the ditch before this retrenchment is 3 toiſes: and there is a banquette before the parapet next to the ditch of about 8 feet, called *berm*; which ſerves to prevent the earth of the parapet (which ſeldom has any revetment) from falling into the ditch. It is to be obſerved, that the ravelin, before which tenaillons are conſtructed, muſt have its ſaliant angle much greater than the former conſtruction makes them; otherwiſe the ſaliant angle of the tenaillons become too acute: for which reaſon we made the capital of this ravelin 45 toiſes, and the faces terminate within 3 toiſes of the ſhoulders.

6. *Conſtruction of Counterguards.*

Fig. 2, 3. Plate II. When the counterguard is placed before the ravelin, ſet off 40 toiſes on the capital of the ravelin from the ſaliant angle A, to the ſaliant angle B, of the counterguard; and 10 from C to D, on the counterſcarp of the ditch.

When the counterguard is before the baſtion, its ſaliant angle F, *fig.* 3. is 50 toiſes from the ſaliant angle E of the baſtion, and the breadth near the ditch of the ravelin 10 toiſes as before. The ditch before the counterguards is 12 toiſes, and its counterſcarp parallel to the faces. Counterguards are made before the ravelin on ſome particular occaſions only; but are frequently conſtructed before the baſtions, as covering the flanks wonderfully well.

7. *Conſtructions of Hornworks.*

Fig. 4. Plate II. Produce the capital of the ravelin beyond the ſaliant angle A, at a diſtance AB of about 80 toiſes; draw DBI at right angles to AB; in which take BD, BI, each equal to 55 toiſes; and on the exterior ſide DI, trace a front of a polygon in the ſame manner as that of the body of the place, making the perpendicular BF 10 toiſes, and the faces 30.

The branches D *a*, I *d*, of the hornwork, when produced terminate, on the faces of the baſtions, within 5 toiſes of the ſhoulders, the ditch of the hornwork is 12 toiſes, and its counterſcarp parallel to the branches; and in the front terminates at the ſhoulders, in the ſame manner as the great ditch before the baſtions. The capital of the ravelin before the front of the hornwork is 35 toiſes, and the faces terminate on the ſhoulders, or rather 2 or 3 toiſes beyond them: and the ditch before the ravelin is 8 toiſes. There are ſometimes retrenchments made within the hornwork, ſuch as S, S; which are conſtructed by erecting perpendiculars to the faces of the ravelins, within 25 toiſes of their extremities. This retrenchment, like all others, has a parapet

Fig. 10

Published as the Act directs by C. Cooke No 17 Paternoster Row March 5.1790.

turfed only with a berm of 8 feet before it; as likewiſe a ditch from 3 to 5 toiſes broad. *Fig*. 5. Plate II. When a hornwork is made before the baſtion, the diſtance DL of the front from the ſaliant angle of the baſtion is 100 toiſes, and the branches terminate on the faces of the adjacent ravelins within 5 toiſes from their extremities; all the reſt is the ſame as before.

8. *Conſtruction of Crown-works.*

Fig. 7. Plate I. From the ſaliant angle, A, of the ravelin, as a centre, deſcribe an arc of a circle with a radius of about 120 toiſes, cutting the capital of the ravelin produced at C; from the point C, ſet off the cords CB, CF, each of them equal to 110 toiſes: and on each of which, as an exterior ſide, conſtruct a front of a polygon of the ſame dimenſions as in the hornwork; that is, the perpendicular ſhould be 18 toiſes, the faces 30, and the branches terminate on the faces of the baſtions within 25 toiſes of the ſhoulders. The ditch is 12 toiſes, the capital of the ravelin 35, and its ditch 8; that is, the ſame as in the hornwork. Sometimes the crownwork is made before the baſtion, as in *fig*. 8. Plate I. The arc is deſcribed from the ſaliant angle A of the baſtion, with a radius of 120 toiſes, as before; and the branches terminate on the faces of the adjacent ravelins within 25 toiſes of their extremities: the reſt of the dimenſions and conſtructions are the ſame as before.

9. *Conſtruction of Covert-ways and Glacis.*

Although we have not hitherto mentioned the covert-way, nevertheleſs all fortifications whatſoever have one; for they are eſteemed to be one of the moſt eſſential parts of a modern fortification; and it is certain, the taking the covert-way when it is in a good condition and well defended, is generally the moſt bloody action of the ſiege. After having conſtructed the body of the place, and all the outworks which are thought neceſſary, lines are drawn parallel to the outmoſt counterſcarp of the ditches, at 6 toiſes diſtant from it; and the ſpace *m n*, *m n*, included between that line and the counterſcarp, will be the covert-way required, as in *Fig*. 9. Plate I. There is in every re-entering angle of the counterſcarp a place of arms, *m*; which is found by ſetting off 20 toiſes from the re-entering angle *a*, on both ſides, from *a* to *b*, and from *a* to *c*; and from the points *b*, *c*, as centres, arcs are deſcribed with a radius of 25 toiſes, ſo as to interſect each other in *d*; then the lines drawn from this interſection to the points *b*, *c*, will be the faces of the places of arms. If lines are drawn, parallel to the lines which terminate the covert way, and the places of arms, at 20 toiſes diſtant from them, the ſpace *x*, *x*, *x*, between theſe lines and thoſe which terminate the covert-way, will be the glacis. At the extremities of the place of arms, are traverſes made, ſuch as *v*, *v*, which ſerve to incloſe them; theſe traverſes are 3 toiſes thick, and as long as the covert-way is broad; and a paſſage is cut in the glacis round them, of about 6 or 8 feet, in order to have a free communication with the reſt of the covert-way. There are alſo traverſes of the ſame dimenſions before every ſaliant angle of the baſtion and outworks, and are in the ſame direction as the faces of thoſe works produced: and the thickneſs lies at the ſame ſide as the parapets. The paſſages round theſe laſt traverſes are likewiſe from 6 to 8 feet wide. In each place of arms are two ſally ports *z z*, which are 10 or 12 feet wide, for the troops to ſally out; in time of a ſiege they are ſhut up, with barriers or gates.

10. *Conſtruction of Arrows and Detached Redoubts.*

An arrow is a work made before the ſaliant angles of the glacis, ſuch as A, *fig*. 9. plate I. It is compoſed of a parapet of 3 toiſes thick, and 40 long; and the ditch before it 5 toiſes, terminating in a ſlope at both ends. The communication from the covert way into theſe arrows is 4 or 5 toiſes wide; and there is a traverſe, *r*, at the entrance, of 3 toiſes thick, with a paſſage of 6 or 8 feet round it. A detached redoubt is a kind of work much like a ravelin, with flanks placed beyond the glacis, ſuch as B; they are made in order to occupy ſome ſpot of ground which might be advantageous to the beſiegers; likewiſe to oblige the enemy to open their trenches farther off than they would do otherwiſe. Their diſtance from the covert-way ought not to exceed 120 toiſes, that it may be defended by muſket ſhot from thence. The gorge *a b* is 40 toiſes: the flanks *a c*, *b f*, which are perpendicular to the gorge, 10; and the faces *c d*, *f d*, 30; the ditch before it is 6 toiſes, ending in ſlopes at both ends: the covert-way are 4; the branches of the covert-way are 42 toiſes long, or thereabouts; the faces of the places of arms *y*, *y*, which are perpendicular to the branches, 10; and the other, which is parallel to them, 14. The communication from the covert-way into the redoubt, is 5 or 6 toiſes wide; and there is a traverſe made juſt at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a ſlope or glacis. If theſe redoubts are above 50 toiſes diſtant from the covert-way, the beſiegers carry their trenches round, and enter through the gorge; by which the troops that are in them are made priſoners of war, if they do not retire betimes; to prevent which, ſome other outworks ſhould be made to ſupport them.

11. *Conſtruction of Second Ditches and Covert-ways.*

Fig. 10. Plate I. When the ground is low, and water to be found, there is often a ditch about 10 or 12 toiſes made round the glacis; and oppoſite to the places of arms are conſtructed lunettes, beyond the ditch; ſuch as D, whoſe breadth on the counterſcarp of the ditch is 10 toiſes, from *b* to *a*, and from *c* to *d*; and the faces *a* L, *d* L, are parallel to thoſe of the places of arms; the ditch before them is from 8 to 10 toiſes wide. The ſecond covert-way is 4 toiſes, the ſemi-gorges of the places of arms, *m*, about 15, and the faces perpendicular to the counterſcarp; the ſecond glacis is from 15 to 18 toiſes broad. This ſecond covert-way has traverſes every where, in the ſame manner as the firſt.

Hitherto we have chiefly adopted the Methods of M. Vauban, as being the moſt generally followed; though in our Judgment thoſe of the ingenious John Muller, Eſq; late Profeſſor of Artillery and Fortification at the Royal Academy at Woolwich, contain many juſt Improvements in this Art: we ſhall therefore, in addition to the former, give them a place in this work; as we are anxious that nothing which appears truly valuable in any Branch of Science may eſcape our notice.

12. *Irregular* FORTIFICATION, Is that wherein the baſtions are uenqual, and unlike; or the ſides and angles not all equal, and equidiſtant. In an irregular fortification, the defence and ſtrength being unequal, there is a neceſſity for reducing the irregular figure, as near as may be, to a regular one; i. e. inſtead of inſcribing it in a circle, it ſhould be inſcribed in an oval, ſo that one half may be ſimilar and equal to the other half. *Fig*. 11. Plate I. repreſents a fortification inſcribed in an oval. In this caſe the ſides CD, CH, on the flat parts are ſtronger than the ſides AB, EF, on the narrow parts, ſuppoſing all the exterior ſides equal, and the place equally fortified. When the angles BCD, CDE, of the polygon are very great, and the beſieger comes within a ſmall diſtance of the works, he cannot approach nearer, without being ſeen in front, except by a direct ſap, with traverſes; and as this way of approaching preſents but a ſmall front, the beſieged, who have a much larger, may oppoſe with peculiar advantage: whereas if the angles HAB, ABC, of the polygon, are very ſmall, the beſiegers may carry their approaches to the counterſcarp itſelf, and have always a larger front than the beſieged; and, as the beſiegers muſt extend their approaches to three fronts, whether they are ſmall or large, the work of the approaches before the front, BCDE will be to the work before the front HABC, as the line BE is to the line HC, nearly, and therefore the front CD, on the flat ſide, is ſtronger than the front AB, on the narrow ſide; conſequently, the longer C D is, ſo that the lines of defence are within the reach of muſket-ſhot, and the angles BCD, CDE, are the ſame, the ſtronger will the front be. The greater the angles of the polygon BCD, CDE, are, the exterior ſides being the ſame, the ſtronger will be the front CD. But, as it is found difficult to inſcribe a polygon in an ellipſe or oval, the following eaſy method will anſwer the purpoſe. Reduce the ſpot of ground to be fortified to the figure ACEG, and draw BE, AF, parallel to each other; draw CH, DG, perpendicular to theſe lines, and at equal diſtance from the points B and E, and let their interval be equal to that of the lines BE and AF; then, draw DC, GH, parallel to AF and BE, and equally diſtant from them; and from their interſections C, D, G, H, with DG, CH, as centres, deſcribe arcs, with a radius equal to CD or GH, ſo as to interſect the lines AF, BE, in A, B, E, F; join the points A, B, E, F, and ABCDEFGH, will be an oblong octagon, having one half ſimilar and equal to the other half. If a hexagon be to be deſcribed, inſtead of drawing the two lines CH, DG, one will be ſufficient; in a decagon there muſt be three, and four in a dodecagon. If the ſides cannot eaſily be made equal, then the ſides AB, EF, on the narroweſt part of the polygon, ſhould be the longeſt, becauſe it is the weakeſt. Muller's Elements of Fort. p. 146. &c.

13. FORTIFICATION, *according to Muller's firſt Method.*

Let AB, *Fig*. 6. Plate II. be the exterior ſide of a polygon of any length, e. gr. a hundred and eighty toiſes; make the perpendicular CD of any length, as the ſixth, fifth or fourth part of the exterior ſide, according to the expence or importance of the place: here it is the ſixth part or thirty toiſes: ſet off fifty toiſes or more for the faces BH, AE, or rather $\frac{2}{7}$ of the exterior ſide; from the ſaliant angle A deſcribe an arc with the radius AI of twenty toiſes, that is two or three toiſes more than the breadth of the ditch; draw from the oppoſite ſhoulder H a tangent HI to that arc, and from the angle A the indefinite line A *b* parallel to that tangent; then, if from the angle A as centre, an arc *a b* be deſcribed with any radius, the flank GH is drawn parallel to the chord *a b*; one of the flanks being thus found, the others will be found by taking the diſtance DG, between the perpendicular and the angle of the flank, and carrying it from the extremities of all the perpendiculars on the lines of defence, as from D to F; this being done, the counterſcarp of the ditch is drawn parallel to the line HI or to A *b*; and having the points or re-entering angle O, its diſtance from the extremity of the perpendicular being carried all round, will give the re-entering angles before the other fronts. The tenailles *h k*, which M. Belidor has invented, and called them rams-horns, are deſcribed, by ſetting off three toiſes from the ſhoulder Q of the baſtion to the point *h*, and drawing *h f* perpendicular to the line of defence; then its interſection *f*, with the other line of defence produced, will be the centre of the arc *h k*. In order to conſtruct the ravelin, ſet off twelve or fifteen toiſes from the ſhoulder E to the point *r*, in the face of the baſtion, and from the angle G of the flank as centre, deſcribe an arc through the point *r*, meeting the perpendicular CD produced at L; from this point L draw the faces, ſo as when produced to fall on the faces of the baſtions within three toiſes of the ſhoulders; the ditch of the ravelin is twelve toiſes. For the retired flanks, find the flank QR as before, on which ſet off five or ſix toiſes for the ſhoulder or orillons; and from a point *g* in the oppoſite face of the baſtion at five toiſes from the ſaliant angle B, draw the broken part of the flank; then draw the retired flank parallel to the line QR, at five toiſes diſtant from it: the orillon may be made round in the manner of M. Vauban's, if it be thought proper.

14. *Muller's ſecond Method of fortifying with detached Baſtions.*

Let the interior ſide AB, *fig.* 8. plate II. of an octagon be a hundred and thirty toiſes; take A *b*, B *n*, equal to twelve toiſes for the ſemi-gorges of the ſmall baſtions, and as much for their capitals A *c*, B *r*; from the points *c*, *r*, draw the lines *c n*, *r b*, to the extremity of the gorges, and make the flanks *b d*, *n m*, perpendicular to the lines of defence; the ditch is ſix toiſes at the ſaliant angles *c*, *r*, and its counterſcarp drawn to the extremities of the flanks of the detached baſtions. The capitals *c* C, *r* D, of the detached baſtions are fifty-five toiſes, and the lines of defence are drawn to the extremities *b* and *n* of the interior flanks; the faces are ſixty; the radius of the arc, which ſerves to determine the poſition of the flanks, eighteen; and the ditch ſixteen at the ſaliant angle. The ravelin is conſtructed by deſcribing an arc from the extremity of the flank, as centre, through a point in the oppoſite face of the baſtion, within twenty toiſes of the ſhoulder, which arc interſects the capital of the ravelin at the ſaliant angle; the faces terminate within five toiſes of the ſhoulders, the ſemi-gorge of the redoubt R is fifteen, its faces parallel to thoſe of the ravelin, and its parapet two toiſes: the ditch of the ravelin twelve, and that of the redoubt ſix. The ſemi-gorges of the places of arms are twenty toiſes, thoſe of the ſtone redoubts *P* within them twelve; the faces of the places of arms are twenty-five; and thoſe of the redoubts parallel to them, with a dry ditch of three toiſes before them; the covert way is ſix, and the glacis twenty. The faces of tenailles are ſixteen toiſes, the paſſage between them and the flanks of the baſtions three; their flanks are parallel to the others, the curtain is drawn through the points where they meet the lines of defence, and the inſide of the tenailles is terminated by lines drawn through the extremities of the flanks of the detached baſtions.

15. *Muller's third Method of fortifying with detached OrillonBaſtions.*

Let the exterior ſide AB, *fig.* 7, plate II. of an octagon be two hundred toiſes, the perpendicular CD forty, that is, a fifth part of the exterior ſide, the faces AE, BF, fifty-five; the radius of the arc which ſerves to determine the poſition of the flanks twenty-two; the ditch ſixteen at the ſaliant angles; the orillon five: the flank is retired five toiſes; and the line *k d*, which terminates the flanks, is drawn from a point *d*, in the face at five toiſes from the ſaliant angle; the ſhoulders of the tenailles are twenty toiſes from thoſe of the baſtions; the flanks parallel to the others, and the curtain is drawn through the points of interſection of the flanks and lines of defence. Take on the lines E *l*, F *h*, drawn from the extremities of the faces parallel to the flanks, and which terminate the inſide of the tenailles, the parts *l n*, *h m*, each of ſix toiſes, for the breadth of the ditch; and upon the exterior ſide *r n*, conſtruct a front of a polygon, by making the perpendicular twelve, and faces twenty toiſes. The redoubts V are made of a wall three feet thick only with loop-holes; their ſaliant angle is determined by the counterſcarps of the inner ditch produced: and the faces terminate within three toiſes of the ſhoulders; the ditch about theſe redoubts is four toiſes. The ravelins and covert-way are conſtructed in the ſame manner as thoſe in the former method. Mr. Muller has made remarks on theſe ſeveral conſtructions, deſigned to ſhew in what reſpects they are ſuperior to the methods of M. Vauban. See Muller's Elem. of Fortification, p. 100, 104, 108, &c.

16. *Conſtruction of Profiles.*

A profile is the repreſentation of a vertical ſection of a work; it ſerves to ſhew thoſe dimenſions which cannot be repreſented in plans, and is neceſſary in the building of a fortification. Profiles are generally conſtructed upon a ſcale of 30 feet to an inch. It would be endleſs to deſcribe all their particular dimenſions; we ſhall therefore lay down the principal rules only, given by M. Vauban, on this ſubject. 1. Every work ought to be at leaſt 6 feet higher than that before it, ſo that it may command thoſe before it; that is, that the garriſon may fire from all the works at the ſame time, with great and ſmall arms, at the beſiegers in their approaches. Notwithſtanding this ſpecious pretence, there are ſeveral authors who object againſt it. For, ſay they, if you can diſcover the enemy from all the works, they can diſcover, by the ſame reaſon, all the works from their batteries; ſo that they may deſtroy them without being obliged to change their ſituation, and thereby diſmount all the guns of the place before they come near it. But if all the works were of the ſame height, thoſe within cannot be deſtroyed, till ſuch time as thoſe before them are taken: guns might be placed in the covert-way and outworks to obſtruct the enemy's approach; and when they come near the place, they might be tranſported into the inner-works; and as the body of the place would be much lower, the expence would be conſiderably diminiſhed. But when works are low, they are eaſily enfiladed by the ricochet batteries, which is a kind of firing with a ſmall quantity of powder, by giving the gun an elevation of 10 or 12 degrees; this might however be partly prevented, by making the parapets near the ſaliant angles, for the ſpace of 8 toiſes on each ſide, 5 or 6 feet higher than the reſt of the works. 2. The covert-way ſhould be lower than the level-ground, otherwiſe the body of the place muſt be raiſed very high, eſpecially where there are ſeveral outworks; this is to be underſtood only when the works exceed each other in height, otherwiſe it need not be below the level. 3. The baſes of all inward ſlopes of earth ſhould be at leaſt equal to the height, if not more. 4. The baſes of all outward ſlopes of earth, two thirds of their heights. 5. The ſlopes of all walls or revetments ſhould be one fifth of their height: or one ſixth might perhaps be ſufficient: the height of a wall is eſtimated from the bottom of the ditch, and not from the beginning of its foundation. 6. The ſlopes of all parapets and traverſes are one ſixth of the breadth: that is, 3 feet towards the field; or the inſide, where the banquettes ſhould be, 3 feet higher than the outſide. 7. When the revetment of a rampart goes quite up to the top, 4 feet of their upper-part is a vertical wall of 3 feet thick, with a ſquare ſtone at the top of it, projecting 6 inches; and a circular one below, or where the ſlope begins, of 8 or 10 inches diameter: they go quite round the rampart, and the circular projection is called the cordon. Where the ſtraight part of the wall ends and the ſlope begins, the wall is always made 5 feet thick; and the counterforts or buttreſſes reach no higher than that place. 8. When the rampart is partly walled, and partly turfed, then one fifth of the height which is turfed muſt be added to 5 feet, to get the thickneſs of the wall above. And having the thickneſs of any wall above, by adding one fifth of its height from the bottom of the ditch, the ſum will be the thickneſs of the wall at the bottom; but if a ſixth part is only taken for the ſlope, then a ſixth part muſt be added. For inſtance, ſuppoſe a rampart of 30 feet high from the bottom of the ditch, and that 10 of which are to be turfed: then the fifth part of 10, which is 2, added to 5, gives 7 for the wall above; and as this wall is 20 feet high, the fifth of which is 4, and 4 added to the thickneſs 7 above, gives 11 for the thickneſs near the foundation.

17. *Marine* FORTIFICATION, Is ſometimes uſed by way of diſtinction from land fortification, and denotes the art of raiſing works fit for the defence of a harbour againſt the attacks of any kind of ſhipping; but the works proper for this purpoſe depend in a great meaſure on the principles employed in the fortification of towns. However, attention ſhould be given to the ſituation of roads or harbours in contriving works for their defence: e. gr. when a town lies open to the ſea, on a curved, or ſtraight bold ſhore, and has before it a ſufficient depth of water and good anchorage; the ſhips, in this ſituation, may be well defended by forts built near the water's edge on each ſide of the anchoring place, ſo contrived as to have two or three batteries, one higher than the other, and furniſhed with a ſufficient number of cannon, carrying ſhot from twenty four to forty eight pounds. A town, in this ſituation, may be defended by a rampart, or wall, well flanked, built along the ſhore, beſides the fortifications on the land ſide. The works along the ſhore ſhould be carried ſo near to the water's edge, that troops, attempting to land under the cannon of a fleet, might not find ground on which to intrench themſelves. Farther, when a harbour, being a bay, has a ſhoal or ſmall iſland lying before its entrance, a ſtrong fort ſhould be built upon the iſland, in a place where it can command the entrance on both ſides, if the iſland be not too large; otherwiſe two or more forts ſhould be erected in ſuch places as may command the avenues to the bay; other forts ſhould alſo be raiſed on the moſt convenient points of lands, forming the mouth of the bay. Again, when the harbour is in a bay, whoſe points, forming the entrance, ſtretch into the ſea, and approach one another within cannon ſhot; ſuch a harbour may be fortified by building on both ſides of its entrance one or more forts; and, if poſſible, a fort ſhould alſo be built within the harbour's mouth in ſuch a manner, that its cannon can rake the ſhipping fore and aft as they come in.

When a harbour is formed by a cluſter of iſlands, it is eaſily fortified, if the channel between the iſlands is not too wide for the command of cannon from one or both ſhores; but if it be too wide, the ſhipping that rides there muſt be defended from the batteries on the ſhore. When the harbour lies in an inlet, or river ſome miles above its mouth, a fort built at each point of the entrance, when the paſſage lies ſtrait, and can be commanded from ſide to ſide, and two others between them and the harbour, but not directly oppoſite, unleſs the breadth of the channel requires it, will be a proper ſecurity for the ſhipping in ſuch a harbour; and if the channel or river is winding, the forts ſhould be built where they can command a reach at leaſt, or be ſo placed at the bends, as to command two adjacent reaches. See Robertſon's Treat. of Marine Fort. part ii. § 2.

In this Syſtem I have taken the utmoſt care to make ſuch ſelections as are of moſt approved worth and eſtimation. For the greater part I have conſulted the valuable Treatiſes of Vauban and Mr. Muller, rejecting thoſe of Cohoern and other Authors, whoſe Methods, from their evident deficiency, are become exploded; and I truſt that this Compendium will afford ample inſtruction to thoſe who deſire to attain a knowledge of Military Architecture.

MUSEUM

FORTISSIMO, in the Italian muſic, is uſed to ſignify *very ſtrong*. It is ſometimes denoted by F F F or *fff*, and intimates that the performers are to play or ſing very loud or ſtrong, to expreſs ſome paſſion, &c.

FORTUNE, a goddeſs worſhipped with great devotion by the ancient Greeks and Romans, who believed her to preſide over human affairs, and to diſtribute wealth and honour at her pleaſure. Plutarch, in an expreſs treatiſe of the Fortune of the Romans, accounts for the practice of the ancient poets, who ſeem to make Jupiter the author of the evils of life. Mankind he obſerves, before the name of Fortune had got into the world, perceiving a certain arbitrary cauſe, diſpoſing of things in an irreſiſtable manner, called it God: but the ſame cauſe being often obſerved to act at random, and without any rule or order at all, the Supreme Being came to be diveſted of the attribute: and Fortune, or Deſtiny, acknowledged in his ſtead. It is not eaſy to unravel what the ancients meant by the name Fortune. The Romans underſtood by it a principle of fortuity, whereby things came to paſs, without being neceſſitated thereto; but what and whence that principle is, they do not ſeem to have ever preciſely thought; whence their philoſophers are often intimating, that men only framed the phantom Fortune, to hide their ignorance; and that they call Fortune whatever befals a man without his knowing for what purpoſe.

Fortune was not conſidered as a deity by the old Romans, but was made ſo by the devotion and folly of the vulgar; Mr. Spencer ſays, that he has ſeen an ancient gem, in which Cybele the mother of the gods, is repreſented as turning away her head from Fortune, in an attitude of diſowning and rejecting her. Polymetis, p. 150, 154, &c. According to the opinion of the heathens, therefore, fortune, in reality, was only the arrival of things in a ſudden and unexpected manner without any apparent cauſe, or reaſon; ſo that the philoſophical cauſe of the word coincides with what is vulgarly called chance. But in religion it had a farther force; altars and temples in great numbers were conſecrated to this fortune, as a deity. This intimates that the heathens had perſonified, and even deified, their chance; and conceived her as a ſort of goddeſs, who diſpoſed of the fate of men at her pleaſure. Hence that invocation of Horace, *O diva, gratum quæ regis Antium*; in the thirty-fifth ode of the firſt book, where he recommends Auguſtus, then preparing for a viſit to Britain, to her protection. From theſe different ſentiments it may be inferred, that the ancients at one time took fortune for a peremptory cauſe, bent upon doing good to ſome and perſecuting others; and ſometimes for a blind, inconſtant cauſe, without any view or determination at all. If then the word fortune has no certain idea in the mouth of thoſe who erected altars to her; much leſs can it be aſcertained what it denotes in the mind of thoſe who now uſe the word in their writings. They who would ſubſtitute the name providence, in lieu of that of fortune, cannot give any tolerable ſenſe to half the phraſes wherein the word occurs.

The painters repreſent her in a woman's habit, with a bandage before her eyes, to ſhew that ſhe acts without diſcernment; and ſtanding on a wheel, to expreſs her inſtability. The Romans, ſays Lactantius, repreſented her with a cornucopia, and the helm of a ſhip, to ſhew that ſhe diſtributes riches, and directs the affairs of the world. In effect, it is with ſuch characters, that we ſee her repreſented on ſo many medals, with the inſcriptions, FORTVNA AVG. FORTVNA REDVX. FORTVNAE AVG. or REDVCIS, &c. Sometimes ſhe is ſeen pointing at a globe before her feet, with a ſceptre in one hand, and holding the cornucopiæ in the other. The Romans had a virile as well as a muliebrian Fortune for the objects of their adoration; the *fortuna virilis* was honoured by the men, and the *fortuna muliebris* by the women. They honoured Fortune alſo under a variety of other appellations. The Romans derived the worſhip of Fortune from the Greeks, under the reign of Servius Tullius, who dedicated the firſt temple to her in the public market. Nero alſo built a temple to Fortune. The Fortune worſhipped at Antium was probably of the moſt exalted character of any among the Romans; if we may judge by the account which Horace gives us of the great ſolemn proceſſions that were made to her. Hor. lib. i. od. xxxv. ver. 22. But the moſt celebrated temple of Fortune was at Præneſte.

Fortune *Tellers*. Pretenders to tell fortunes, and to any crafty ſcience for the diſcovery of ſtolen goods, are puniſhable by impriſonment, pillory, and binding to their good behaviour, and ſhall be deemed vagabonds. Stat. 9 Geo. II. cap. 5. ſect. 4. Stat. 17 Geo. II. cap. 5. ſect. 2. See Conjuration.

FORUM, in Roman antiquity, is uſed in divers acceptations: ſometimes for a place of traffic, anſwering to our market place; in which ſenſe it has uſually ſome adjective added to it, as *forum boarium*, the *beaſt market*; *forum piſcarium*, the *fiſh market*; *olitorium forum*, the *herb market*. Forum is uſed for any place where the governor of a province convenes his people to give judgment, according to courſe of law. Forum was alſo a public ſtanding place in the city of Rome, where cauſes were judicially tried, and orations delivered to the people.

FOSS, or Fosse, in fortification, &c. a ditch, or moat. The word is French, formed of the Latin participle *foſſum*, of the verb *fodio*, *I dig*.

Foss, Fossa, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit, or perforation. When the aperture is very narrow, it is called a ſinus. In the cranium there are ſix internal, and fourteen external foſſes. The cavity of the orbit, which contains the eye is a foſs.

FOSSA *Magna*, or *Navicularis*, is an oblong cavity, forming the inſide of the *pudendum muliebre*, and which preſents itſelf upon opening the labia; and in the middle whereof are the *carunculæ myrtiformes*. See Syſtem of Anatomy, Part V. Sect. XI.

FOSSIL, in natural hiſtory is uſed in a general ſenſe, for any thing dug up, or found under ground. Such are all minerals, metals, rock ſalts, &c. Foſſils are uſed in a more confined ſenſe by Linnæus, to denote the third claſs of ſtones: and includes petrified, concrete, and terrene ſubſtances. The chymiſts divide all bodies into three claſſes, or kingdoms; viz. *foſſil* or *mineral*, *vegetable*, and *animal*. Foſſils may be diſtinguiſhed into, 1. Such as are *natives* of the earth; and, 2. Such as are *adventitious*, and repoſited therein by any extraordinary means; as earthquakes, deluges, &c.

Fossils, *Native*, or Fossils *properly ſo called*, are ſenſible bodies generated and growing in the earth, and found either buried in it, or lying on its ſurface; whoſe conſtituent parts are ſo ſimple and homogeneous, that there is no apparent diſtinction of veſſels and juices; nor any difference between the part, and the whole. The firſt perſon who attempted to reduce the ſubject of foſſils into a regular ſcience, was Dr. Woodward, who publiſhed a method of arrangement, founded on the growth, ſtructure, and texture of foſſils. But this ſyſtem being found inſufficient for diſtinguiſhing the bodies of the foſſil kingdom with accuracy, was ſucceeded by the method of dividing theſe bodies, according to the various changes produced on them by fire, into *calcarii*, *apyri*, *vitreſcentes*, &c. eſtabliſhed by the Swediſh and German authors; and this method now univerſally prevails. The mineralogy of Wallerius is on this plan; however, other writers, as Dr. Hill, Mendes da Coſta, &c. have endeavoured to form a new ſyſtem from the combined principles of Woodward and Wallerius; and arranged foſſils, not only according to their growth, texture, and ſtructure, but alſo their principles and qualities, as diſcovered by the aid of fire and acid menſtrua. Native foſſils are either *ſimple*, or *compound*.

Fossils, *Simple*, are thoſe, whoſe parts, however divided, are all of the ſame nature, i. e. of the ſame gravity, magnitude, figure, hardneſs, and mobility. Such is quickſilver, which, however divided, is always found the ſame. Of foſſils naturally and eſſentially ſimple, ſome according to Dr. Hill, in his Hiſtory of Foſſils, are neither inflammable nor ſoluble in water, of which he reckons three ſeries; as thoſe of no regular ſtructure or determinate figure, comprehending the ſimple *earths*, of which there are ſeveral orders and genera; thoſe of a regular ſtructure, and no determinate figure, of which ſeries there are three claſſes, viz. the *talcs*, the *fibrariæ*, and the *gypſums*, each of which is again ſubdivided into orders and genera; and thoſe of a regular ſtructure and a determinate figure, comprehending three claſſes, viz. the *ſelenitæ*, *cryſtals*, and *ſpars*, which include various orders and genera. Other ſimple Foſſils, though uninflammable, are ſoluble in water; ſuch are the ſimple ſalts: and others, on the contrary, are inflammable, but not ſoluble in water; of which there are two ſeries, viz. thoſe of a ſolid form, comprehending the *phlogidiaugia* and the *phlogiſcieria*.

Fossils, *Compound*, are thoſe which may be divided into different, or diſſimilar parts. As antimony, which may be reſolved by fire into ſulphur, and a metalline part. Of theſe compound foſſils, in the diſtribution of Dr. Hill, ſome are neither inflammable, nor ſoluble in water, of which there are four ſeries; as thoſe that are found in continued ſtrata, comprehending the two claſſes of *compound earths*, ſubdivided into *loams* and *moulds*, and their ſubordinate genera; and *ſtones*, including three orders, and under thoſe eight genera; thoſe again, that are formed in detached maſſes of a regular ſtructure and determinate figure, comprehending the two claſſes of *ſeptariæ* and *ſiderochita*; thoſe formed in detached maſſes, of no determinate figure or regular ſtructure, and compoſed of a cryſtalline or ſparry matter, debaſed by an admixture of earth in various proportions, comprehending four claſſes, viz. the *ſcrupi*, the *ſemipellucid gems*, the *pebbles* and *ſands*; and thoſe that are formed of a fine pellucid ſubſtance, of great hardneſs, and never fouled by an admixture of earthy, or any other coarſe matter, but ſuſceptible of elegant tinges from metalline particles, of which ſeries there is only one claſs, including the pellucid *gems*, of which there are two genera, viz. ſuch as retain one ſimple and permanent appearance in all lights, as the diamond, the carbuncle, the ruby, the garnet, the hyacinth, the amethyſt, the ſapphire, the beryl, the emerald, the praſius, the chryſolite, and the topaz; and ſuch as exhibit variable colours, when viewed in different lights, as the opal and aſteria. Other compound foſſils are ſoluble in water, but not inflammable, as all the *metallic ſalts*, ſome of which are found naturally in a ſolid form, as *vitriol* and *chalcanthum*; and others in a liquid ſtate, ſuch as the water from which the blue Cyprian vitriol is procured; and others are inflammable, but not ſoluble in water, of which there are three claſſes, viz. the marcaſites, the pyritæ, and phlogoniæ.

Dr. Hill adds a third general diviſion of foſſils, including the metallic foſſils, ſome of which are fuſible by fire, and not malleable in their pureſt ſtate; ſuch are antimony, biſmuth, cobalt, zinc, and quickſilver; and others are fuſible by fire, but concrete again in the cold, and become malleable, or diſtenſible, and ductile under the hammer: ſuch are tin, iron, copper, ſilver, lead, and gold. See Stones.

Fossils, *Adventitious*, or *Foreign*, include the ſubterraneous exuviæ of ſea and land animals, and even vegetables; as ſhells, bones, teeth, leaves, ſtalks, &c. which are found buried in great abundance, in divers parts of the earth. See *Foſſile* Plants, Shells, Wood, &c.

Theſe extraneous foſſils have employed the curioſity of ſeveral of our lateſt naturaliſts, who have each their ſeveral ſyſtems to account for the ſurpriſing appearances of petrified ſea fiſhes, in places far remote from the ſea, and on the tops of mountains; ſhells in the middle of quarries of ſtone; and of elephants teeth, and bones of divers animals, peculiar to the ſouthern climates, and plants only growing in the Eaſt, found foſſile in our northern and weſtern parts. Some will have theſe ſhells, &c. to be real ſtones, and ſtone plants, formed after the uſual manner of other figured ſtones; of which opinion is the learned Dr. Liſter. That author, though he allows of petrified ſhells on the ſea ſhores, will by no means agree that there are any ſuch petrifactions in the midland countries. The ſhell-like ſtones, found in our quarries, he contends, are *lapides ſui generis*; and never were any part of an animal. His reaſons are, that their matter and texture are perfectly the ſame with that of the rock or quarry, whence they are taken; as iron-ſtone ſhells are all iron-ſtone; ſpar, or cryſtaline, all ſpar, &c. Add, that the quarries of different ſtone yield different ſorts of theſe ſhells; and that there are no animals in nature, which yield any thing exactly like many of them. But to this erroneous doctrine it is to be anſwered, 1. That theſe ſhells found under ground are often perfectly conformable to thoſe in the ſea in figure, ſubſtance, magnitude, &c. 2. The ſubſtance of theſe foſſils often alſo differs eſſentially from the common ſubſtance of ſtones. It is true, we frequently find them covered, or impregnated with a mineral, or ſtony matter, which has gradually inſinuated itſelf into the pores; but it is in many caſes eaſy to diſtinguiſh that matter from the ſubſtance of the ſhell. Another opinion is, that theſe foſſil ſhells, with all other foreign bodies found within the earth, as bones, trees, plants, &c. were buried therein at the time of the univerſal deluge; and that having been penetrated either by the bituminous matter, abounding chiefly in watery places, or by the ſalts of the earth, they have been preſerved entire, and ſometimes petrified. Others think, that the waters of the ſea, and the rivers, with thoſe which fell from heaven, turned the whole ſurface of the earth upſide down; after the ſame manner as the waters of the Loire, and other rivers, which roll in a ſandy bottom, overturn all their ſands, and even the earth itſelf, in their ſwellings and inundations; and that in this general ſubverſion, the ſhells came to be interred here, fiſhes there, trees there, &c. See Journ. des Scavans, 1715. p. 19. and Mem. de. Trev. 1713.

But nobody has ſet this ſyſtem in a better light than Dr. Woodward, in his Natural Hiſtory of the Earth. That author, purſuing and improving the hypotheſis of Dr. Burnet, maintains the whole maſs of earth, with every thing belonging thereto, to have been ſo broken and diſſolved at the time of the deluge, that a new earth was then formed in the boſom of the water, conſiſting of different ſtrata, or beds of terreſtrial matter, ranged over each other uſually, according to the order of their ſpecific gravities. By this means, plants, animals, and eſpecially fiſhes, and ſhells, not yet diſſolved among the reſt, remained mixed and blended among the mineral and foſſil matters; which preſerved them, or at leaſt aſſumed and retained their figures and impreſſions, either indentedly, or in relievo.

Camerarius attacks this opinion of Dr. Woodward, and goes yet higher, and advances many new notions. He ſuppoſes, 1. That the greateſt part of the ſhells now dug from under-ground, had been placed there before the deluge, that is, at the time of the creation, when God ſeparated the earth from the waters. 2. That, without having recourſe to the diſſolution of the earth by the waters, one might ſuppoſe moſt of them to have ſlipped in at the chinks and crevices naturally happening after the waters were retired, and the earth ſufficiently drained. 3. That particular inundations might have ſwept moſt of theſe ſhells into the places where we now find them. 4. That the ſea may have wrought, or caſt up, moſt of theſe ſhells through ſubterraneous ſpiracles and canals. 5. That God has created divers ſtony and metalline bodies, perfectly like the vegetables and animals, which we ſee on earth, and in the ſea. To all theſe ſuppoſitions, Dr. Woodward anſwers, 1. It is no ways probable, God ſhould create ſuch a number of ſhell-fiſh of the ſame ſpecies at once; and that purely with a deſign to deſtroy them all again ſo ſoon after; that among the foſſil ſhells of the ſame ſpecies it is eaſy to diſtinguiſh thoſe of different ages; that ſome appear preciſely ſuch as we now find them in the ſpring, the ſeaſon when the deluge began; that they are not only ſhells we find under-ground, but alſo bones of quadrupeds, plants, and trees of extraordinary ſizes, and which are not of the number of aquatics; and, that the waters were ſeparated from the earth on the third day, and that none of theſe things were created, till afterwards. 2. That, on the ſecond ſuppoſition, theſe ſhells would be diſpoſed perpendicularly, and not horizontally, as they are always found; that we ſhould ſometimes find them in the clefts of the earth, where in fact there are none but what are broken. 3. That we have no acquaintance with any of theſe pretended inundations; that they could never have brought ſhells, ſtags, horns, and elephants teeth, from America, and the Eaſt Indies to England, and the other parts of Europe; nor the fruits, pines, and beeches, frequently found far greater than any of our growth. Add, that theſe particular inundations muſt have riſen to the tops of the higheſt mountains, and of conſequence they muſt have been general. 4. On the fourth ſuppoſition it muſt be held, that God did not only create all theſe ſeveral bodies in the entrails of the earth, but their ſeveral parts, and the ſeparate pieces and fragments of thoſe parts; a piece of ſhell, for inſtance; one ſide of a ſhell, which conſiſts of two; a ſhell void of the fiſh it ſhould contain; beards of corn, without the grain; pieces of cedar-bark, without the wood; pieces of bullocks hides without fleſh and bones; human ſkins without bodies: a bone without the reſt of the ſkeleton; a tooth without the jaw, &c. Add, that the foſſil ſhells have not only external, but eſſential reſemblance to ſea-ſhells; both, e. gr. yielding by analyſis, a quantity of ſea-ſalt; that, among the foſſil teeth of fiſhes, we meet with ſome apparently worn; and, laſtly, that the ſhell-fiſh, called *purple*, has a long ſharp tongue, by means whereof it pierces other ſhells, and picks the fiſh out of them; and that in digging under-ground we actually meet with divers of theſe ſhells thus pierced. Can ſuch minute thorough-paced reſemblances be the accidental effects of a *luſus naturæ?* See Marine *Remains*, Petrifaction, *Formed* Stones, Shells, &c.

FOUL, in the ſea-language, is uſed when a ſhip has been long untrimmed, ſo that graſs, weeds, periwinkles, barnacles, or the like, ſtick or grow to her ſides under water. In this ſtate, ſhe is ſaid to be *foul*. A ſhip is ſaid to make *foul water*, when, being under ſail, ſhe comes into ſuch ſhoal, or low water, that though her keel doth not touch the ground, yet ſhe comes ſo near it, that the motion of the water under her raiſes the mud from the bottom, and ſo fouls the water. Foul is alſo a ſea term, importing the running of one ſhip againſt another. This happens ſomtimes by the ungovernable violence of the wind, and ſometimes by the careleſſneſs of the people on board; and ſometimes happens to ſhips of the ſame convoy: ſometimes to ſuch as meet accidentally; and ſometimes to ſuch as are in port, by means of others coming in. The damages occaſioned by running foul, are of the nature of thoſe in which both parties muſt bear a part; they are uſually made half to fall upon the ſufferer, and half upon the veſſel which did the injury: but in caſes where it is evidently the fault of the maſter of the veſſel, he alone is to bear the damage.

Foul *Wind* expreſſes that which is unfavourable, or contrary to the courſe of the ſhip, in oppoſition to large or fair.

Foul *Feeding*, in farriery, denotes a voracious appetite, to which ſome horſes are ſubject, which, though not properly a diſeaſe, is the cauſe of various maladies. It is commonly the effect of ſome latent diſtemper, and frequently occaſioned by worms irritating the inteſtines. See Syſtem of Farriery, Sect. XXII.

Foulness *in Wounds*. When what the ſurgeon calls uncleanneſs or foulneſs is perceived in a wound, that is, when the fleſh in it looks fungous, black, putrid, or livid, it muſt be well cleanſed before any attempts are made to heal it. Different methods of effecting this have been in uſe at different times among the ſurgeons; the ancients uſed honey, but the moſt uſual practice now is, to apply a digeſtive ointment made of turpentine diſſolved in the yolk of an egg, and afterwards mixed with honey of roſes; but where this is not found ſtrong enough for the purpoſe, the Egyptian ointment is to be uſed, mixed either with ſpirit of wine, or with the common digeſtive. To theſe digeſtive ointments a ſmall quantity of aloes and myrrh may alſo very properly be added; and where more ſtrength is required in them, a ſmall quantity of red precipitate is to be added. The uſe of lime-water as a detergent is alſo very great, and yet more ſo, if there be added to every pint of it twenty or thirty grains of ſublimate; this makes what is called the *phagedænic* water. Applications of this kind are to be continued till the wound is clean, and then it is to be healed with the common digeſtives.

FOUNDATION, that part of a building which is under-ground; or that maſs of ſtone, &c. which ſupports a building; or upon which the walls of the ſuperſtructure are raiſed; or, it is the coffer, or bed, dug below the level of the ground, to raiſe a building upon. The foundation either takes up the whole area and extent of the building, as when there are to be vaults, cellars or the like; or it is drawn in cuts, or trenches, as when only walls are to be raiſed. The foundation is properly ſo much of the maſonry, as reaches as high as the ſurface of the ground; and this is always to be proportioned to the load or weight of the building which it is to bear. The foundations of buildings are either *natural* or *artificial*. *Natural*, is when we build on a rock, or a very ſolid earth; in which caſe we need not ſeek for any farther ſtrengthening. *Artificial*, where the ground is ſandy, or marſhy, or has lately been dug. In the former caſe, the architect muſt adjuſt the depth of the foundation by the height, weight, &c. of the building:

a ſixth part of the whole height is looked on as a medium; and as to thickneſs, double that of the width of the wall, is a good rule. Architects ought to uſe the utmoſt diligence in regard to foundations, ſince of all errors which may happen in building, an error in this point is moſt pernicious.

When the ground is very bad, you muſt get large oaken piles of ſuch a length as may reach the ſound ground, and whoſe diameter muſt be about one twelfth part of their length: theſe muſt be driven down with a machine, as cloſe to one another as poſſible, and that under the middle walls as well as the outer ones; and upon their tops large planks are to be pinned down. But if the ground be only faulty in ſome places, arches may be turned over them, by which means no part of the weight of the building will reſt upon them. As to the rules neceſſary to be obſerved in conſtructing the ground-work, they are theſe: 1. That the bottom of the trench be made exactly level. 2. That the loweſt ledge or row be all of ſtone, laid cloſe together. 3. That the breadth of the ground-work be at leaſt double that of the wall that is to be raiſed on it. However, art ought always to give way to diſcretion, for the breadth may be regulated according to the goodneſs of the ground, and the weight of the intended edifice. 4. That the foundation be made to diminiſh as it riſes, only care muſt be taken that it do ſo equally on both ſides. 5. That you ought never to build upon the ruins of an old foundation, unleſs well aſſured of its depth and goodneſs. For further particulars ſee Syſtem of ARCHITECTURE.

FOUNDATION is alſo uſed figuratively for the eſtabliſhment of a city, empire, or the like. The Romans reckoned their years from the foundation of Rome, *ab urbe condita*; which we ſometimes expreſs by *ab U. C.* Chronologers make 745 years from the Iſraelites paſſing out of Egypt, to the foundation of Rome.

FOUNDATION alſo denotes a donation, or legacy, either in money, or lands, for the maintenance and ſupport of ſome community, hoſpital, ſchool, lecture, or other work of piety.

FOUNDER, he who lays a foundation, or who founds and endows a church, ſchool, religious houſe, or other work of charity and piety. Founder is alſo an artiſt that melts or caſts metals into various forms, for divers uſes; as guns, bells, ſtatues, bombs, types or printing characters; and other ſmall works, as candleſticks, buckles, &c.

FOUNDER, in the ſea language; a ſhip is ſaid to *founder* at ſea, when by an extraordinary leak, or a great ſea breaking in upon her, ſhe is ſo filled with water, that ſhe cannot be freed of it, nor is able to ſwim under it, but ſinks with the weight thereof.

FOUNDERY, or FOUNDRY, the art of melting and caſting all ſorts of metals; particularly braſs, iron, bell-metal, &c. The word is alſo uſed for a place, or work-houſe, furniſhed with furnaces or forges for this purpoſe.

FOUNDERY *of Statues, Great Guns, and Bells.* The art of caſting ſtatues in braſs is very ancient; inſomuch that its origin was too remote and obſcure even for the reſearch of Pliny; an author admirably ſkilled at diſcovering the inventors of other arts. All we can learn for certain is, that it was practiſed, in all its perfection, firſt among the Greeks, and afterwards among the Romans; and that the number of their ſtatues conſecrated to their gods and heroes, ſurpaſſed all belief. See STATUE.

The ſingle cities of Athens, Delphos, Rhodes, &c. had each three thouſand ſtatues; and Marcus Scaurus alone, though only ædile, adorned the circus with no leſs than three thouſand ſtatues of braſs, for the time of the Circenſian games. This taſte for ſtatues was finally carried to ſuch a pitch, that it became a proverb, that in Rome the people of braſs were not leſs numerous than the Roman people. Among us, the caſting of ſtatues was but little known or practiſed before the ſeventeenth century. As to the *caſting of guns*, it is quite modern; and it were, perhaps, to be wiſhed, we were as ignorant of it as the ancients. All authors agree, that the firſt cannon were caſt in the fourteenth century; though ſome affix the event to the year 1338, and others to 1380. See CANNON and GUNNERY.

The *caſting of bells* is of a middle ſtanding, between the other two. The uſe of bells is certainly very ancient in the weſtern church: and the ſame were likewiſe once uſed in the church of the Eaſt. But at preſent F. Vanſleb aſſures us, in his ſecond account of Egypt, he had found but one bell in all the Eaſtern church, and that in a monaſtery in the Upper Egypt.

FOUNT, or FONT, among printers. See FONT.

FOUNTAIN, in philoſophy, a ſpring or ſource of water riſing out of the earth. Among the ancients, fountains were held ſacred, and even worſhipped as a kind of divinities. For the phenomena, theory, and origin of fountains or ſprings, ſee SPRING.

Artificial FOUNTAIN, called alſo a *jet-d'eau*, is a contrivance by which water is violently ſpouted upwards. See HYDRAULICS.

FOURCHEE, or FOURCHY, in heraldry. A croſs *fourchee* is that forked at the ends.

FOURTH, in muſic, one of the harmonic intervals, or concords. The fourth is the fourth in order of the concords. It conſiſts in the mixture of two ſounds, which are in the ratio of 4 to 3; i. e. of ſounds produced by chords, whoſe length are to each other as 4 to 3. It is called *fourth*, becauſe containing four terms, or ſounds, between its extremes, and three degrees; or, as being the fourth, in the order of the natural ſcale, from the fundamental.

FOWL, among zoologiſts, denotes the larger ſorts of birds, whether domeſtic or wild: ſuch as geeſe, pheaſants, partridges, turkeys, ducks, &c. Fowls are again diſtinguiſhed into two kinds, viz. *land* and *water* fowl, theſe laſt being ſo called from their living much in and about water: alſo into thoſe which are accounted *game*, and thoſe which are not. See the article GAME.

Our common poultry came originally from Perſia and India. Ariſtophanes calls the cock, the Perſian bird, and that it was known in that country before Darius and Megabyzus; and theſe birds are now found wild in the iſle of Tinian, and other iſlands in the Indian ocean: in this ſtate their plumage is black and yellow, and their combs and wattles purple and yellow. They have been naturalized in this country before the arrival of the Romans, for Cæſar inform us, that they were one of the forbidden foods of the old Britons. They were probably imported by the Phœnicians, who traded to Britain about five hundred years before Chriſt. For all other domeſtic fowls, turkies, geeſe, and ducks excepted, we ſeem to be indebted to our conquerors, the Romans. The wild fowl were our own from the earlieſt period. It will appear remarkable enough, if we conſider how much the tame poultry which we have imported from diſtant climates has increaſed, and how much thoſe wild birds of the poultry kind that have never yet been taken into keeping have been diminiſhed and deſtroyed. They are all thinned; and many of the ſpecies, eſpecially in the more cultivated and populous parts of the kingdom, are utterly unſeen.

Under birds of the poultry kind may be ranked all thoſe that have white fleſh, and, comparatively to their head and limbs, have bulky bodies. They are furniſhed with ſhort ſtrong bills for picking up grain, which is their chief and often their only ſuſtenance. Their wings are ſhort and concave; for which reaſon they are not able to fly far. They lay a great many eggs; and as they lead their young abroad, the very day they are hatched, in queſt of food, which they are ſhown by the mother, and which they pick up for themſelves, they generally make their neſts on the ground. The toes of all theſe are united by a membrane as far as the firſt articulation, and then are divided as in thoſe of the former claſs. Under this claſs we may therefore render the common cock, the peacock, the turkey, the pintada or Guinea hen, the pheaſant, the buſtard, the grous, the partridge, and the quail. They all bear a ſtrong ſimilitude to each other, being equally granivorous, fleſhy, and delicate to the palate. They are among birds what beaſts of paſture are among quadrupeds, peaceable tenants of the field, and ſhunning the thicker parts of the foreſt, that abounds with numerous animals, who carry on unceaſing hoſtilities againſt them. As nature has formed the rapacious claſs for war, ſo ſhe ſeems equally to have fitted theſe for peace, reſt, and ſociety. Their wings are but ſhort, ſo that they are ill formed for wandering from one region to another; their bills are alſo ſhort, and incapable of annoying their oppoſers: their legs are ſtrong indeed; but their toes are made for ſcratching up their food and not for holding or tearing it. Theſe are ſufficient indications of their harmleſs nature; while their bodies, which are fat and fleſhy, render them unweildy travellers, and incapable of ſtraying far from each other.

Accordingly, we find them chiefly in ſociety: they live together; and though they may have their diſputes, like all other animals, upon ſome occaſions; yet, when kept in the ſame diſtrict, or fed in the ſame yard, they learn the arts of ſubordination; and in proportion as each knows his ſtrength, he ſeldom tries a ſecond time the combat where he has once been worſted. In this manner, all of this kind ſeem to lead an indolent voluptuous life. As they are furniſhed internally with a ſtrong ſtomach, commonly called a gizzard, ſo their voraciouſneſs ſcarce knows any bounds. If kept in cloſe captivity, and ſeparated from all their former companions, they have ſtill the pleaſure of eating left; and they ſoon grow fat and unweildy in their priſon. To ſay this more ſimply, many of the wilder ſpecies of birds, when cooped or caged, pine away, grow gloomy, and ſome refuſe all ſuſtenance whatever; none except thoſe of the poultry kind grow fat, who ſeem to loſe all remembrance of their former liberty, ſatisfied with their indolence and plenty. The ſea fowls which come on ſhore in immenſe numbers to rooſt, in the north iſlands of Scotland, ſet their watches and centinels at diſtant poſts, to give them notice of any danger; on the leaſt alarm from theſe, the whole body riſes, but without ſuch notice they are not to be alarmed, by almoſt any thing. The people of the country know this; and when they go out take them they employ all their art to take the centinels without noiſe; this they ſometimes ſucceed in, and when they do, they often afterwards catch three hundred of the others, or more, in one night. Phil. Tranſ. N° 233.

The laying of theſe ſea birds is leſs certain as to time than might be imagined. They can occaſionally defer it; and as they uſually lay in a rainy ſeaſon, if the rain does not come on at the uſual time, they will defer it ſome weeks; and if the April moon goes far in May, that alſo has been obſerved to hinder them from laying ten or twelve days longer than ordinary.

Tame FOWL are a neceſſary part of the ſtock of a country farm; and yield conſiderable ſervice and profit, by their eggs, brood, feathers, dung, &c. They may be kept at a very eaſy expence near any highway-ſide: as being able to ſhift for themſelves, during the greateſt part of the year, by their feeding on inſects, worms, ſnails, and almoſt any thing eatable. The oldeſt hens are always the beſt for ſitting, and the youngeſt for laying; but no ſort will be good for either, if kept too fat.

The beſt age to ſet a hen for chickens, is, from two years old to five; and the moſt proper month to ſet them in, is February; though it may be done, to good purpoſe, at any time between that and Michaelmas. One cock will ſerve ten hens. A hen ſits but twenty days; whereas geeſe, ducks, and turkeys, ſit thirty. Buck-wheat, or French wheat, or hemp-ſeed, it is ſaid, makes them lay faſter than any other food; and the ſame buck-wheat, either whole, or ground, and made into a paſte, fats them apace; though the common food for that purpoſe, is barley-meal; or pollard mixed up with hot water or milk. A gooſe will ſcarce ſit on any but her own eggs; a hen will ſit indifferently on all. The lighteſt coloured geeſe are the beſt, and thoſe that begin to lay the ſooneſt; as they have a chance of hatching twice in one year. They begin to lay in the ſpring, and lay twelve or ſixteen eggs. Green geeſe are begun to be fattened at a month old, and will be fat in a month more. Old geeſe are chiefly fattened at ſix months old, in or after the harveſt. A wild gooſe, if red-footed and hairy, is old; but if white-footed, and not hairy, ſhe is young. When the eggs are ſet under a hen, or other fowl, it is adviſeable to mark the upper ſides thereof; and when ſhe goes to feed, to note whether ſhe minds to turn them upſide down, or not; if ſhe neglect that office, it may be done for her.

FOWLING, the act, or art, of catching birds with nets, birdlime, decoys, and other devices; as alſo of breeding up the ſame. For particulars, ſee the article Decoy.

FOX, an animal of the dog kind; much reſembling the common dog in form, and of the ſize of the ſpaniel. It is chiefly diſtinguiſhed by its long ſtraight tail, with a white tip to it. It differs, however, from the common dog in the length, denſe diſpoſition, and ſoftneſs of the hairs, eſpecially thoſe about its tail, which is buſhy, much admired by the animal itſelf; and in cold weather wrapped round its noſe; and in its ſmell, which is peculiarly rank and diſagreeable. The ſmell of its urine is remarkably fœtid; inſomuch that the animal covers it in the earth. It is ſaid that the fox makes uſe of its urine as an expedient to force the cleanly badger from its habitation; however, it makes uſe of the badger's hole. Its uſual colour is a reddiſh tawny, though it is ſometimes found white, and ſometimes black. Its manner of digging itſelf a hole in the earth, is alſo a cuſtom wholly different from all the dog-kind; and it is far from the tameneſs of that animal, being with difficulty made to loſe its fierceneſs. Of all animals the fox has the moſt ſignificant eye, by which it expreſſes every paſſion of love, fear, hatred, &c. The fox is a crafty, lively, libidinous animal; it breeds only once a year, unleſs ſome accident befalls its firſt litter, and brings four or five young, which, like puppies, are born blind. The fox is a native of moſt northern countries, and there are three varieties of it, differing a little in form, but not in colour. They are diſtinguiſhed in Wales by different names. The *greyhound fox* is the largeſt, talleſt, and boldeſt, and will attack a grown ſheep or wether; the *maſtiff fox* is leſs, but more ſtrongly built: the *cur fox* is the leaſt, lurks about hedges, out-houſes, &c. and is the moſt pernicious to the feathered tribe. The firſt of theſe has a white tip to the tail: the laſt a black. The ſkin of this animal is furniſhed with a ſoft and warm fur, which in many parts of Europe is uſed to make muffs and fine cloths. A fox in the firſt year is called a cub; in the ſecond, a fox, and afterward an old fox. It is a beaſt of chaſe, uſually very prejudicial to the huſbandman, by taking away and deſtroying his lambs, geeſe, and poultry. It will feed on fleſh of any kind; and when urged by hunger eat carrots and inſects; and, near the ſea-coaſts, for want of other food, eat crabs, ſhrimps, or ſhell-fiſh. In France and Italy it does incredible damage to the vineyards, by eating the grapes, of which it is very fond. The fox is a great deſtroyer of rats, and field animals. It ſecures its booty by digging holes in ſeveral places; and if a whole ſtock of poultry ſhould happen to be its prey, will bring them one by one, thruſt them in with its noſe, and conceal them by ramming the looſe earth upon them, till the calls of hunger induce him to devour them. The common way to catch him is by gins, which being baited, and a train made by drawing raw fleſh acroſs his uſual paths or haunts to the gin, it proves an inducement to lure him to the place of deſtruction. They are alſo taken with greyhounds, hounds, terriers, and nets; it is a commendable exerciſe to hunt theſe miſchievous beaſts, the nature of which in many reſpects is like that of wolves. See Hunting.

FRACTION, in arithmetic and algebra, a part or diviſion of an unit, or integer; or, a number which ſtands to an unit in the relation of a part to its whole. The word literally imports a broken number. Fractions are uſually divided into *decimal*, and *vulgar*. For a full explanation, with the ſeveral rules, ſee the Syſtem of Arithmetic, Articles XI. and XII. and Syſtem of Algebra, Sect. III.

FRACTURE, in medicine and ſurgery, a breach, or rupture of a bone; or a ſolution of continuity in a bone, when it is cruſhed, or broken, by ſome external cauſe. See Syſtem of Surgery.

FRÆNUM, or Frenum, bridle, in anatomy, a name given to divers ligaments, from their office in retaining and curbing the motions of the parts they are fitted to. *Frænum linguæ*, or bridle of the tongue, is a membranous ligament, which ties the tongue to the os hyoides, larynx, fauces, and lower part of the mouth. In ſome ſubjects the *frænum* runs the whole length of the tongue, to the very tip; in which caſes, if it were not cut, it would take away all poſſibility of ſpeech. *Frænum* of the *penis*, is a ſlender ligament, whereby the prepuce is tied to the lower part of the glans of the penis. See Syſtem of Anatomy, Part III. Sect. IV.

Nature varies in the make of this part; it being ſo ſhort in ſome, that, unleſs divided, it would not admit of perfect erection. There is alſo a kind of little *frænum*, faſtened to the lower part of the *clitoris*.

FRAIGHT, or Freight, in navigation and commerce, the hire of a ſhip, or of a part of it, for the conveyance and carriage of goods from one part or place to another; or the ſum agreed on between the owner and the merchant, for the hire and uſe of a veſſel. The fraight of a veſſel is uſually agreed on either at the rate of ſo much for the voyage, or by the month, or per ton. Fraighting, or letting out veſſels on fraight, or hire, is one of the principal articles in the trade of the Hollanders: they are the carriers of all the nations of Europe, and their purveyors; notwithſtanding that their country produces little or nothing, and that they are forced to have every thing neceſſary for the building of a veſſel from other countries. If merchandizes in caſks, as wines, oils, &c. have ſo run out in carriage, that the veſſels are left empty, or almoſt empty, the merchant may relinquiſh them, and the maſter be obliged to take them for their fraight; though this does not hold of any other goods damaged, or diminiſhed of themſelves, or through accidents.

Fraight is alſo uſed for the burthen, or lading of a ſhip, or the cargo of goods, &c. which ſhe has on board.

FRAISE, in fortification, a kind of defence conſiſting of pointed ſtakes, driven parallel to the horizon, into the retrenchments of a camp, a half-moon, or the like, to ward off and prevent any approach or ſcalade.

FRAME, in joinery, &c. a kind of caſe, wherein a thing is ſet or incloſed, or even ſupported; as a window frame, a frame of a picture, of a table, &c.

Frame is alſo a machine uſed in divers arts, and more particularly for a ſort of loom, whereon artizans ſtretch their linens, ſilks, ſtuffs, &c. to be embroidered, quilted, or the like.

FRAMING *of a Houſe*, all the timber work therein, viz. the carcaſe, flooring, partitioning, roofing, cieling, beams, aſhlering, &c.

FRANCHISE, a privilege or exemption from ordinary juriſdiction. Franchiſe is alſo uſed for an immunity from the ordinary tributes and taxes. This is either real or perſonal; that is, either belonging immediately to the perſon; or accruing on account of this or that place, or office of immunity. Theſe franchiſes, being royal privileges, or branches of the king's prerogative, ſubſiſting in the hands of a ſubject, are derived from the crown by grant or charter, and, in ſome caſes, are held by preſcription and uſage. They may be veſted either in natural perſons, or bodies politic; in one man, or in many; but the ſame identical franchiſe that has before been granted to one, cannot be beſtowed on another, for that would prejudice the former grant, The principal kinds of franchiſes are the following: to be a county palatine is a franchiſe veſted in a number of perſons. It is likewiſe a franchiſe for a number of perſons to be incorporated, and ſubſiſt as a body politic, with a power to maintain perpetual ſucceſſion, and do other corporate acts; and each individual member of ſuch corporation is alſo ſaid to have a franchiſe or freedom. Other franchiſes are to hold a court leet; to have a manor or lordſhip; or, at leaſt, to have a lordſhip paramount, to have waifs, wrecks, eſtrays, treaſure-trove, royal-fiſh, forfeitures, and deodands; to have a court of one's own, or liberty of holding pleas or trying cauſes; to have the cognizance of pleas, which is a ſtill greater liberty, being an excluſive right, ſo that no other court ſhall try cauſes ariſing within that juriſdiction; to have a bailiwick, or liberty exempt from the ſheriff of the county, wherein the grantee only and his officers are to execute all proceſs; to have a fair or market, with the right of taking toll, either there, or at any other public places, as bridges, wharfs, and the like; which tolls muſt have a reaſonable cauſe of commencement, elſe the franchiſe is illegal and void; or, laſtly, to have a foreſt, chaſe, park, warren, or fiſhery, endowed with privileges of royalty.

FRANCISCAN *Monks*, *Friars Minor*, or *Grey-Friars*; religious of the order of St. Francis, founded by him in the year 1209. The rule of the Franciſcans, as eſtabliſhed by St. Francis himſelf, is briefly this: they are to live in common, to obſerve chaſtity, and to pay obedience to the pope and their ſuperiors. Before they can be admitted into the order, they are obliged to ſell all they have, and give it to the poor: they are to perform a year's noviciate; and, when admitted, never to quit the order upon any account. They are to faſt from the feaſt of All-ſaints, to the Nativity: this order produced 4 popes, 42 cardinals, and an infinite number of patriarchs.

FRANK, or FRANC, a term literally ſignifying free and open, or exempt from public impoſitions and charges; as frank, confeſſion, frank fair, frank letter, &c.

FRANK *Language*, or *Lingua* FRANCA, is a kind of jargon, ſpoken on the Mediterranean, and particularly throughout the coaſts and ports of the Levant; compoſed of Italian, Spaniſh, French, vulgar Greek, and other languages. The *lingua franca* is the trading language; and is thus called from the Franks, a common appellation given in the Levant to all the European merchants and traders who come thither to traffick.

FRANK *Letters*, or *Letters free of Poſtage*. The privilege of ſuch letters was claimed by the houſe of commons in 1660, when the firſt legal ſettlement of the preſent poſt-office was made; but afterwards dropped on a private aſſurance from the crown, that this privilege ſhould be allowed the members. Accordingly a warrant was conſtantly iſſued to the poſt-maſter general, directing the allowance thereof to the extent of two ounces in weight; till at length it was expreſsly confirmed by ſtat. 4 Geo. III. cap. 24. which adds many new regulations, rendered neceſſary by the abuſes crept into the practice of franking; whereby the annual amount of *franked letters* had gradually increaſed from 23,600l. in 1715, to 170,700l. in 1763. Blackſt. Com. vol. i. p. 322.

FRANK, or *Franc*, an ancient coin, either of gold or ſilver, ſtruck and current in France. The value of the gold franc was ſomething more than that of the gold crown; the ſilver franc was a third of the gold one: this coin is long out of uſe, though the term is ſtill retained as the name of a money of account; in which ſenſe it is equivalent to the livre, or 20 ſols.

FRANKINCENSE, or ſimply INCENSE, an odoriferous aromatic gum, or reſin, anciently burnt in temples, as a perfume, and now uſed in pharmacy, as an agglutinant and ſtrengthener. The word is formed from the Latin *incenſum, burnt*; as alluding to its ancient uſe in temples. Frankincenſe diſtils from inciſions made in a tree called *arbor thurifera*, during the heats of ſummer. But notwithſtanding the great uſe of this gum, both in the ancient religion, and the modern medicine, the tree that produces it, or even the place where the tree grows, is but little known.

Frankincenſe was formerly burnt in the temples of all religions, to do honour to the divinities that were there adored. Many of the primitive Chriſtians were put to death, becauſe they would not offer incenſe to idols. In the Romiſh church they ſtill retain the uſe of incenſe in ſome of their ceremonies; always at high maſs, and at the elevation of the hoſt at veſpers; and at ſolemn funerals, beſtowing it on ſuch perſons as they would honour, as on prelates, &c. and ſometimes alſo on the people.

FRATERIA, of *frater, brother*, a fraternity, brotherhood, or ſociety of religious perſons, who were bound to pray for the good health and life, &c. of their living brethren, and the ſouls of thoſe that were dead. In the ſtatutes of the cathedral church of St. Paul, London, collected by Ralph Baldock, dean, 1295, there is one chapter *De frateria benificiorum eccleſia S. Pauli, &c.*

FRATERNITY, in a civil ſenſe, is uſed for a guild aſſociation, or ſociety of perſons, united into a body, for ſome common intereſt or advantage. For the origin, uſe, &c. of fraternities, ſee COMPANY and GILD.

FRATERNITY, in a religious ſenſe, is a ſociety of perſons meeting together to perform ſome exerciſes of devotion, or divine worſhip. In the Romiſh church, ſuch fraternities are very numerous and conſiderable, being moſt of them eſtabliſhed by royal patents; as the fraternity of the Scapulary; of St. Francis's cord. The biſhop may hinder the eſtabliſhment of any ſuch fraternity in his dioceſe. There are nine different ſorts of fraternities, or confrairies, in France, viz. 1. Of devotion. 2. Of charity, or mercy. 3. Of penitents, under divers names. 4. Of pilgrimage. 5. Of merchants to procure the divine favour on their endeavours. 6. Of officers of juſtice. 7. Of the ſufferings of Chriſt. 8. Of arts and trades of divers kinds. And, 9. Of factions.

FRATRICIDE, of *frater, brother*; and *cædo, I kill*, the crime of murdering one's brother. See PARRICIDE. Cain committed the firſt *fratride*; and the empire of Rome began with a *fratricide*.

FRAUD, FRAUS, a ſecret underhand deceit, or injury, done to any one. To export or import goods by fraud, or fraudulently, is to do it by indirect ways, in order to avoid the paying of duty, &c. if they be permitted goods; or if they be contraband goods, to avoid the penalties adjudged by the laws.

FRAXINUS, the Aſh; a genus of the diœcia order, belonging to the polygamia claſs of plants. There are ſix ſpecies; of which the moſt uſeful is the common aſh, which is ſo well known, that it needs no deſcription.

FRAY literally ſignifies to fret; as cloth or ſtuff does by rubbing, or over-much wearing. Among hunters a deer is ſaid to *fray his head*, when he rubs it againſt a tree, to cauſe the ſkins of his new horns to come off.

FREAM, among farmers, arable or ploughed land worn out of heart, and laid fallow till it recovers.

FRECKLES, *Lentigines*, ſpots of a yellowiſh colour, of the bigneſs of a lentile ſeed, ſcattered over the face, neck, and hands. Freckles are either natural, or proceeding accidentally from the jaundice, or the action of the ſun upon the part. Heat, or a ſudden change of the weather, will often cauſe the ſkin to appear of a darker colour than natural; and thereby produce what is called tan, ſunburn, and morphew, which ſeem to differ only in degree; and uſually diſappear in winter. Perſons of a fine complexion, and ſuch whoſe hair is red, are the moſt ſubject to freckles, eſpecially in thoſe parts which they expoſe to the air. To remove freckles, put juice of lemons in a glaſs vial, and, mixing it with ſugar and borax finely powdered, let it digeſt eight days, and then uſe it. Homberg propoſes bullock's gall mixed with alum, and, after the alum has precipitated, expoſed three or four months to the ſun in a cloſe vial, as one of the beſt remedies known for the removing of freckles.

FREE, a term variouſly uſed; but generally in oppoſition to conſtrained, confined, or neceſſitated. See FRANK. Thus, a man is ſaid to be free, who is out of priſon; and a bird is free, when let out of the cage: free from pain, i. e. void of pain; we ſay, a free air, a free paſſage, &c. FREE, in ſpeaking of things endowed with underſtanding, has a more peculiar relation to the will, and implies its being at full liberty. The ſtoics maintain, that their ſage or wiſe men alone are free. FREE is alſo uſed in oppoſition to ſlave. The moment a ſlave ſets foot on Engliſh ground, he becomes to ſome purpoſes free. The fineſt legacy the ancient Romans could leave their ſlaves, was their freedom.

FREE *Bench*, or *franc banc*, ſignifies that eſtate in copyhold lands, which the wife hath after the deceaſe of her huſband, for her dower, according to the cuſtom of the manor. Fitzherbert calls *free banc* a cuſtom, whereby, in certain cities, the wife ſhall have her huſband's whole lands, &c. for her dower. Thus, at Orleton, in the county of Hereford, the relict of a copyhold tenant formerly was admitted to her *free bench*, i. e. to all her huſband's copyhold land, during her life, at the next court after her huſband's death. In the manors of Eaſt and Weſt Enbourne, in Berks, if a cuſtomary tenant died, the widow had a *free bench* in all his copyhold lands, only *dum ſola & caſta fuerit*: if ſhe committed incontinency, ſhe forfeited her eſtate; but if ſhe came into court, riding backwards on a black ram, with his tail in her hand, rehearſing a certain form of words, in the nature of a confeſſion and petition, the ſteward was bound by the ancient cuſtom to reſtore to her her *free bench*. The words were theſe:

Here I am
Riding upon a black ram,
Like a whore as I am:
And for my crincum crancum
I have loſt my bincum bancum,
And for my tail's game
Have done this worldly ſhame;
Therefore, pray, Mr. Steward, let me have my land again.

The like cuſtoms were held alſo in the manor of Chadleworth, in Berks; that of Tor, in Devonſhire; and in ſome other parts of the Weſt.

FREE *Booter*, a name given to pirates, who ſcour the American ſeas; particularly ſuch as make war againſt the Spaniards.

FREE *Chapel*, is a chapel founded by the king, and by him exempted from the juriſdiction of the ordinary. A ſubject may alſo be licenſed by the king to build ſuch a chapel, and by his charter may exempt it from the viſitation of the biſhop, &c.

FREE or *Imperial Cities* in Germany, are thoſe not ſubject to any particular prince; but governed, like republics, by their own magiſtrates. FREE-*ſtate*, is a republic governed by magiſtrates, elected by the free ſuffrages of the inhabitants.

FREE *Maſon*. See MASON.

FREE *Stone*, a whitiſh ſtone, dug up in many parts of England, that works like alabaſter; but is more hard and durable, being of excellent uſe in buildings, &c. It is a kind of the gritt ſtone, but finer ſanded, and a ſmoother ſtone; and it is called *free-ſtone*, from its being of ſuch a conſtitution as to be cut freely in any direction. The qualities of the ſeveral kinds of *free-ſtone* in common uſe in the ſeveral parts of Europe, are very different. They all agree in this general property indeed, that they are ſofter while in the quarry than when they have been ſome time expoſed to the air: but even this general property differs greatly in degree. They have a ſort of grey *free-ſtone* in uſe at Paris, of which we do not ſeem yet to have met with any quarries in England, though probably enough there are ſuch, which has this property in ſo eminent a degree, that the expence of working it is in a meaſure ſaved. Our Portland ſtone, of the fineſt kind, which is white, and of a cloſe gritt, is very fit for hewing or carving, but it will neither reſiſt water nor fire, which is a very ſingular circumſtance in ſo denſe a ſtone; while the *free-ſtone* of Kent, which is leſs beautiful to the eye, and is of a greyiſh colour, and conſiderably cloſe, though of a larger grain, reſiſts the air and water very well. The *free-ſtone* of Derbyſhire, on the other hand is ſo brittle as to be unfit for any fine working, and ſo coarſe and open in its texture that it lets water through; yet it bears the fire extremely well, and is fit for ovens, hearths, &c. Phil. Tranſ. N° 93.

FREEDOM, the quality or ſtate of being free.

FREEDOM *of a City, Town, &c.* denotes a right or capacity of exerciſing a certain trade or employment in that city or town corporate, and of being elected to the dignities and offices thereof. It is procured regularly, by ſerving an apprenticeſhip; but ſometimes purchaſed with money, and ſometimes conferred as a favour or compliment. Freedom of the will, a ſtate or faculty of the mind, wherein all the motions of our will are in our power, and we are enabled to determine on this or that; to do good or evil, without any force or conſtraint from any external cauſe whatever.

Freedom *of Conſcience.* See Liberty, and Toleration.

FREEHOLD, Frank Tenement, *liberum tenementum*, is land, or tenement, which a man holds in fee-ſimple, fee-tail, or for a term of life. Freehold is of two kinds, in deed, and in law. The firſt is the real poſſeſſion of land or tenement in fee, fee-tail, or for life: the other is the right a man has to ſuch land or tenement before his entry or ſeizure. A freehold, by the common law, cannot commence *in futuro*, but it muſt take effect preſently, either in poſſeſſion, reverſion, or remainder. Whatever is part of the freehold goes to the heir; and things fixed thereto may not be taken in diſtreſs for rent, or in execution, &c. No man ſhall be diſſeiſed of his freehold, by ſtat. Magna Charta, cap. 29. but by judgment of his peers, or according to the laws of the land: nor ſhall any diſtrain freeholders to anſwer for their freehold, in any thing concerning the ſame, without the king's writ. Freehold eſtates, of certain value, are required by ſtatutes to qualify jurors, electors of the knights of the ſhire in parliament, &c. For the method of finding the value of freehold eſtates, ſee Syſtem of Annuities, Problem VI.

Freehold is likewiſe extended to ſuch offices as a man holds in fee, or for life.

FREEZE, or Frize, in architecture, that part of the entablature of columns, between the architrave and corniche. The *freeze* is properly a large, flat face, or member, ſeparating the architrave from the corniche. See Syſtem of Architecture, on the Orders of Architecture in general.

Freeze, in commerce, a kind of cloth or ſtuff. See Frize.

FREEZING, *Congelation*, in phyſiology, the fixing of a fluid, or depriving it of its natural mobility, by the action of cold; or it is the act of converting a fluid ſubſtance into a firm, coherent, rigid one, called ice. See Congelation.

Freezing *Rain*, or *Raining Ice*, a very uncommon kind of ſhower, which fell, in the Weſt of England, in December, anno 1672. See Phil. Tranſ. N° 90. This rain, as ſoon as it touched any thing above ground, as a bough, or the like, immediately ſettled into ice: and, by multiplying and enlarging the icicles, it broke all down with its weight. The rain that fell on the ſnow, immediately froze into ice, without ſinking in the ſnow at all. It made an incredible deſtruction of trees, beyond any thing in all hiſtory. "Had it concluded with ſome guſt of wind," ſays a gentleman on the ſpot, "it might have been of terrible conſe-"quence." "The ſprig of an aſh-tree, of juſt three quarters of a pound, being weighed, the ice thereon weighed ſixteen pounds. Some were frighted with the noiſe in the air; till they diſcerned it was the clatter of icy boughs daſhed againſt each other." Dr. Beale obſerves, that there was no conſiderable froſt obſerved on the ground during the whole; whence he concludes, that a froſt may be very fierce, and dangerous, on the tops of ſome hills: while, in other places, it keeps at two, three, or four feet diſtance above the ground, rivers, lakes, &c. and may wander about very furiouſly, in ſome places, and be remiſs in others, not far off. This froſt was followed by glowing heats, and a wonderful forwardneſs of vegetation.

FRENCH, in general, ſomething belonging to France: thus we ſay, the French language, French cuſtoms, polity, &c. The French language is made up of Latin, Greek, Teutonic, and the language ſpoken by the old Gauls. It is natural, and eaſily pronounced; and therefore uſed by moſt nations in Europe in converſing with foreigners. There are very few compound words in French; which is acknowledged to be its diſadvantage. It has alſo few diminutives: but as to purity, eaſineſs, and flexibility, it yields to none.

French *Graſs*, a name given by our farmers to a plant raiſed for the food of cattle, and more properly called *ſaint-foin*. It had its name French graſs, from its coming originally to us from France, and from its uſe in ſerving both freſh and dried for the food of cattle. See Syſtem of Agriculture, Sect. IX.

FRESCO, in the Arts, a kind of painting performed on freſh plaſter, or on a wall laid with mortar not yet dry: and with water-colours. This ſort of painting has a great advantage: by its incorporating with the mortar, and drying along with it, it is rendered extremely durable; and never fails or falls, but along with it. The Italians, from whom we borrow the term, call it *freſco*, becauſe it is frequently uſed for walls, alcoves, and other buildings, in the open air. Vitruvius, lib. vii. cap. 4. calls it *udo tectorio.* Painting in *freſco* is very ancient, having been practiſed in the earlieſt ages of Greece and Rome. It is chiefly performed on walls and vaults, newly plaſtered with lime and ſand; but the plaſter is only to be laid, in proportion as the painting goes on; no more being to be done at once, than the painter can diſpatch in a day, while it dries. Before he begins to paint, a cartoon or deſign is uſually made on paper, to be calked, and transferred to the wall, about half an hour after the plaſter is applied. The ancients painted on ſtucco; and we may remark in Vitruvius what infinite care they took in making the incruſtation or plaſtering of their buildings to render them beautiful and laſting; though the modern painters find a plaſter made of lime and ſand preferable to it; both as it does not dry ſo haſtily, and as being a little browniſh, it is fitter to lay colours on than a ground ſo white as ſtucco. In this kind of painting, all the compound and artificial colours, and almoſt all the minerals, are ſet aſide, and ſcarce any thing is uſed but earths; which are capable of preſerving their colour, defending it from the burning of the lime, and reſiſting its ſalt, which Vitruvius calls its bitterneſs. For the work to come out in all its beauty, the colours muſt be laid on quick, while the plaſter is yet moiſt; nor ſhould they ever be retouched, dry, with colours mixed up with the white of an egg, or ſize, or gum, as ſome workmen do; becauſe ſuch colours grow blackiſh; nor do any preſerve themſelves, but only ſuch as were laid on haſtily at firſt. The colours uſed, are white made of lime ſlacked long before, and white marble duſt; oker, both red and yellow; verditer; lapis lazuli; ſmalt; black chalk, &c. All which are only ground, and worked up with water; and moſt of them grow brighter and brighter, as the *freſco* dries. The bruſhes and pencils for this work ought to be long and ſoft, otherwiſe they will rake and raiſe the painting. The colours ſhould be full, and flowing from the bruſh; and the deſign perfect; for, in this work, you cannot alter or add upon any colour.

FRESH *Water*, is that not tinctured or impregnated with ſalt, or ſaline particles, enough to be diſcoverable by the ſenſe. Such generally is that of ſprings, rains, wells, lakes, &c. Dr. Liſter is of opinion, that the natural and original ſtate of water is to be ſalt; the freſhneſs he ſuppoſes to be accidental, and to be owing to the vapours of plants, and the breadth of animals therein; and to the exhalations raiſed by the ſun. Others will have all water originally freſh, and take its ſaltneſs to be accidental; to account for which, a great number of hypotheſes have been framed. The ſaltneſs of water is a foreign, and in moſt caſes a hurtful quality. It renders it not only nauſeous to the taſte, but greatly prejudicial to the body; and it is generally agreed, that thoſe waters, *cæteris paribus*, are beſt, not only for drinking, but alſo for œconomical uſes, as waſhing, boiling, and brewing, which are the freeſt from ſaltneſs. The dulcifying, or making of ſalt water freſh, is a ſecret, that has been long ſought with great attention. For an account of the principal attempts that have been made with this view, ſee *Sea*-Water.

Fresh *Wind*, ſignifies ſtrong, but not violent; hence when the gale increaſes, it is ſaid to freſhen.

FRET, or Frett, in architecture, a kind of knot, or ornament, conſiſting of two liſts, or fillets; variouſly interlaced, or woven, and running at parallel diſtances, equal to their breadth.

Fret, or Frette, in heraldry, is a bearing conſiſting of ſix bars, croſſed, and interlaced, *fretwiſe*.

FRETTY, or Frette, in heraldry, is where there are divers bars laid acroſs each other.

FRET-*Work*, an enrichment of frets, or a place adorned with ſomething in manner thereof. *Fret-work* is ſometimes uſed to fill up and enrich flat, empty ſpaces; but it is principally practiſed in roofs, which are fretted over with plaſter-work.

FRIABLE is applied by naturaliſts to bodies, to denote them tender and brittle, eaſily crumbled or reduced to powder between the fingers; their force of coheſion being ſuch as eaſily expoſes them to ſuch ſolution. Such as pumice, and all calcined ſtones, burnt alum, &c. *Friability* is ſuppoſed to ariſe hence, that the body conſiſts wholly of dry parts, irregularly combined, and which are readily ſeparated, as having nothing unctuous or glutinous to bind them together.

FRIAR, or Frier, by the Latins called *frater*, the Italians *fra*, and the French *frere*, that is, *brother*, is a term common to the monks of all orders; founded on this, that there is a kind of fraternity, or brotherhood, preſumed between the ſeveral religious perſons of the ſame convent or monaſtery. The kinds of friars are very numerous; Auguſtine friars; Dominican, or black, or preaching friars; Franciſcan, or grey, or begging friars; and Carmelites, or white friars. Friar, in a more peculiar ſenſe, is reſtrained to ſuch monks as are not prieſts; for thoſe in orders are uſually dignified with the appellation of *father*.

FRIBURGH, Fridburgh, or Fritheborg, among our Anglo-Saxon anceſtors, denoted the ſame as frank-pledge did after the time of the conqueſt. Every man in this kingdom was anciently aſſociated in ſome decennary, or company of ten families, who were pledged, or bound, for each other, to keep the peace, and obſerve the law. If any offence was done by one, the other nine were to anſwer it; that is, if the criminal fled from juſtice, they had thirty days allowed to apprehend him; if he was not taken in that time, he who was the *friburgh*, i. e. the principal pledge of the ten, ſhould take two of his own number, and the chief pledges of three neighbouring *friburghs*, with two others out of each of the ſaid *friburghs*, who were to purge themſelves, and their *friburgh*, of the forfeiture and flight of the criminal. If they could not do this, the principal pledge, with the other eight, were to make ſatisfaction. Great men were not combined in any ordinary decenna, or dozen, as being deemed a ſufficient aſſurance for themſelves and their menial ſervants.

FRICASSEE, a diſh, or meſs, haſtily dreſſed in a frying-pan, and ſeaſoned with butter, oil, or the like. We ſay a *fricaſſee* of pullets, of rabbets, of tench, of tripe, of frogs, of eggs, of peas, &c.

FRICTION, the act of rubbing or grating the ſurface of one body againſt that of another, called alſo *attrition*. The phenomena ariſing upon the friction of divers bodies, under different circumſtances, are very numerous and conſiderable. Mr. Hawkſbee gives us a number of experiments of this kind; particularly of the attrition, or friction of glaſs, under various circumſtances, the reſult of which was, that it yielded light, and became electrical. All bodies by friction are brought to conceive heat; many of them to emit light; particularly a cat's back, ſugar, beaten ſulphur, mercury, ſea-water, gold, copper, &c. but, above all, diamonds, which, when briſkly rubbed againſt glaſs, gold, or the like, yield a light equal to that of a live coal when blowed by the bellows. See Syſtem of ELECTRICITY. Part I. Sect. II.

FRICTION, in mechanics, denotes the reſiſtance a moving body meets with from the ſurface on which it moves. For the laws and principles, ſee Syſtem of MECHANICS.

FRICTION, in medicine and ſurgery, denotes the act of rubbing a diſeaſed part with oils, unguents, or other matters; in order to eaſe, relieve, and cure it. Frictions are much uſed of late in venereal caſes. They prefer the applying of mercury externally by way of friction, to that of giving it internally, to raiſe a ſalivation. There are alſo frictions with the fleſh-bruſh, a linen cloth, or the hand only. Frictions of any kind are a ſort of exerciſe which contribute generally to health; as they excite and ſtir up the natural warmth, divert defluctions, promote perſpiration, open the pores of the ſkin, and carry off ſtagnant humors. The fleſh-bruſh, Dr. Cheyne obſerves, is an exerciſe extremely uſeful for promoting a full and free perſpiration, and circulation. Every body knows the effect of currying horſes; that it makes them ſleek, gay, lively, and active; ſo as ever to be judged equivalent to half the feeding. This it can no otherwiſe effect, but by aſſiſting nature to throw off the recrements of the juices, which ſtop the free circulation, and, by conſtant friction, irritation and ſtimulation, to bring the blood and ſpirits to the parts moſt diſtant from the ſeat of heat and motion; and ſo plump up the ſuperficial muſcles. And the ſame effect it would have in other creatures, and man himſelf, if managed in the ſame manner, and with the ſame care and regularity. Perſons, therefore, of weak nerves, and ſedentary lives, would do well to ſupply the want of other exerciſe with ſpending half an hour, morning and night, in currying and rubbing their whole body, eſpecially their limbs, with a fleſh-bruſh. But this means of health is moſt advantageouſly uſed when the *primæ viæ* are moſt empty.

FRIDAY, the ſixth day of the week ſo called from Friga, a goddeſs worſhipped by the Saxons on this day. It is a faſt-day in the church of England, in memory of our Saviour's crucifixion, unleſs Chriſtmas-day happens to fall on Friday which is always a feſtival.

Good **FRIDAY**. See PASSION-*Week*.

FRIGATE, a ſhip uſually of two decks, light built, deſigned for ſwift ſailing. When it hath but one deck, and conſequently is of a ſmaller ſize, they call her a light frigate. Frigates mount from twenty to thirty-eight guns, and are eſteemed excellent cruizers. The name was formerly known only in the Mediterranean, and applied to a long kind of veſſel, navigated in that ſea with ſails and oars. The Engliſh were the firſt who appeared on the ocean with theſe ſhips, and equipped them for war as well as for commerce. See NAVAL *Affairs*.

FRIGATE *Built* denotes the diſpoſition of the decks of ſuch merchant ſhips as have a deſcent of four or five ſteps from the quarter deck and fore-caſtle into the waiſt, in contradiſtinction to thoſe whoſe decks are on a continued line for the whole length of the ſhip, which are called galley built.

FRIGHT. This paſſion has been known not only to cauſe, but to cure diſeaſes. Mr. Boyle mentions agues, gout, and ſciatica, cured by this means. See Works, abr. p. 82, &c. It is a commonly known cure for the hiccough, to put the patient in a ſudden fright.

FRIGID, *Cold*, is variouſly uſed. A frigid ſtyle, is a low, jejune manner of diction; wanting force, warmth of imagination, figures of ſpeech, &c.

FRIGID *Zone*, or *Frozen Zone*, in geography. See Syſtem of GEOGRAPHY.

FRIGIDITY is alſo uſed in the ſame ſenſe with impotence.

FRIGORIFIC, of *frigus*, *cold*, and *facio*, *I make*, in phyſics, ſomething that occaſions cold.

FRINGILLA, in ornithology, according to Linnæus the 72d genus and belonging to the 6th order, called Paſſeres. Latham in his improved arrangement makes it the 37th genus, and belonging to the 3d order. For the claſſification, ſee the Syſtem. For the repreſentation, ſee Plate II. The bill is conical, ſtraight, and ſharp pointed. There are no leſs than 30 ſpecies comprehended under this genus, diſtinguiſhed principally by varieties in their colour. The following are natives of Britain:

The *carduelis*, or *goldfinch*, with the quill feathers red forwards, and the outermoſt without any ſpots; the two outermoſt are white in the middle, as the reſt are at the point. The young bird, before it moults, is grey on the head; and hence it is termed by the bird catchers a *grey pate*. There is a variety of goldfinches called by the London bird catches a *cheverel*, from the manner in which it concludes its jerk. It is diſtinguiſhed from the common ſort by a white ſtreak, or by two, ſometimes three white ſpots under the throat. Their note is very ſweet; and they are much eſteemed on that account, as well as for their great docility. Towards winter, they aſſemble in flocks; and feed on ſeeds of different kinds, particularly thoſe of the thiſtle. It is fond of orchards, and frequently builds in an apple or pear tree: its neſt is very elegantly formed of fine moſs, liverworts, and bents, on the outſide; lined firſt with wool and hair, and then with the goſlin or cotton of the ſallow. It lays five white eggs, marked with deep purple ſpots on the upper end. The *cælebs*, or *chaffinch*, has its name from its delighting in chaff. This ſpecies entertains us agreeably with its ſong very early in the year, but towards the latter end of ſummer aſſumes a chirping note: both ſexes continue with us the whole year. What is very ſingular in Sweden, the females quit that country in September, migrating in flocks into Holland, leaving their mates behind; in the ſpring they return. In Hampſhire Mr. White has obſerved ſomething of this kind; vaſt flocks of females with ſcarcely any males among them. Their neſt is almoſt as elegantly conſtructed as that of the goldfinch, and of much the ſame materials, only the inſide has the addition of ſome large feathers. They lay four or five eggs of a dull white colour, tinged and ſpotted with deep purple. The *domeſtica*, or *ſparrow*, theſe birds are proverbially ſalacious: they breed early in the ſpring; make their neſts under the eaves of houſes, in holes of walls, and very often in the neſts of the martin, after expelling the owner. Linnæus tells us (a tale from Albertus Magnus), that this inſult does not paſs unrevenged: the injured martin aſſembles its companions, who aſſiſt in plaſtering up the entrance with dirt; then fly away, twittering in triumph, and leave the invader to periſh miſerably. They will often breed in plum trees and apple trees, in old rooks neſts, and in the forks of boughs beneath them. The *linaria*, or *linnet*, hath the bottom of the breaſt of a fine blood red, which heightens as the ſpring advances. Theſe birds are much eſteemed for their ſong: they feed on ſeeds of different kinds, which they peel before they eat: the ſeed of the linum or flax is their favourite food: from whence the name of the linnet tribe. They breed among furze and white thorn: the outſide of their neſt is made with moſs and bents, and lined with wool and hair. They lay five whitiſh eggs, ſpotted like thoſe of the goldfinch. The *cannabina*, or *red headed linnet*, is leſs than the former, and hath a blood-coloured ſpot on the forehead. It is a common fraud in the bird ſhops in London, when a male bird is diſtinguiſhed from the female by a red breaſt, as in the caſe of this bird, to ſtain or paint the feathers, ſo that the deceit is not eaſily diſcovered, without at leaſt cloſe inſpection. Theſe birds are frequent on our ſea coaſts; and are often taken in flight-time near London: it is a familiar bird; and is cheerful in five minutes after it is caught. The *canaria*, or *Canary bird*, hath a whitiſh body and bill, with the prime feathers of the wings and tail greeniſh. It was originally peculiar to thoſe iſles to which it owes its name. Geſner is the firſt who mentions them; and Aldrovand ſpeaks of them as rarieties; that they were very dear on account of the difficulty attending the bringing them from ſo diſtant a country, and that they were purchaſed by people of rank alone. Olina ſays, that in his time there was a degenerate ſort found on the iſle of Elba, off the coaſt of Italy, which came there originally by means of a ſhip bound from the Canaries to Leghorn, and was wrecked on that iſland. Theſe birds will produce with the goldfinch and linnet; and the offspring is called a *mule bird*, becauſe, like that animal, it proves barren. They are ſtill found on the ſame ſpot to which we were firſt indebted for the production of ſuch charming ſongſters; but they are now become ſo numerous in our country, that we are under no neceſſity of croſſing the ocean for them.

FRITH, in its moſt uſual acceptation, ſignifies an arm of the ſea; ſuch are the Frith of Forth, or of Edinburgh, the Frith of Clyde, Murray Frith, &c.

FRIT, or **FRITT**, in the glaſs manufacture, is the matter or ingredients, whereof glaſs is to be made; when they have been calcined, or baked in a furnace. A ſalt drawn from the aſhes of the plant kali, or from fern, or other plants mixed with ſand, or flint, and baked together, makes an opake maſs, called by glaſsmen *frit*.

FRITILLARIA, **FRITILLARY**; a genus of the monogynia order, belonging to the hexandria claſs of plants. See Syſtem of BOTANY, Sect. V.

There are five ſpecies, all of them bulbous-rooted flowery perennials, producing annual ſtalks from about one foot to a yard or more high, terminated by large, bell-ſhaped, liliaceous flowers, of a great variety of colours. They are all propagated by offſets, which they furniſh abundantly from the ſides of their roots, and which may be ſeparated every ſecond or third year; they are hardy plants, and will thrive in any of the common borders.

FRIZE, or **FREEZE**, in commerce, a kind of woollen cloth, or ſtuff, for winter wear, being frized, or knapt, on one ſide: whence, in all probability, it derives its name. Of frizes, ſome are croſſed, others not croſſed: the former are chiefly of Engliſh manufacture, the latter of Iriſh.

FRIZING *of Cloth*, a term in the woolen manufactory, applied to the forming of the knap of a cloth, or ſtuff, into a number of little hard burrs, or prominences, covering almoſt the whole ground thereof. Some cloths are only frized on the back-ſide, as black cloths; others on the right ſide, as coloured and mixed cloths, ratteens, bays, frizes, &c. Frizing may be performed two ways; one with the hand, i. e. by means of two workmen, who conduct a kind of plank, that ſerves as a freezing inſtrument. The other way is by a mill, worked either by water, or a horſe, or, ſometimes, by men. This latter is eſteemed the better way of frizing, becauſe the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly.

FROG, an amphibious animal. For a particular deſcription, ſee Rand.

Frog *Fiſh* of Surinam, a very ſingular animal, of which a figure is given by Mr. Edwards, Hiſt. of Birds, Vol. I. There is no ſpecimen in the Britiſh Muſeum, nor in any private collection, except that of Dr. Fothergill. It was brought from Surinam in South America. Frogs, both in Aſia and Africa, according to Merian, change gradually from fiſhes to frogs, as thoſe in Europe; but after many years revert again into fiſhes, though the manner of their change has never been inveſtigated. In Surinam theſe fiſhes are called *jakjês*. They are cartilaginous, of a ſubſtance like our muſtela, and exquiſite food: they are formed with regular vertebræ, and ſmall bones all over the body divided into equal parts; are firſt darkiſh, and then grey: their ſcales make a beautiful appearance. Whether this animal is, in its perfect ſtate, a ſpecies of frog with a tail, or a kind of water lizard, Mr. Edwards does not pretend to determine; but obſerves, that when its ſize is conſidered, if it ſhould be deemed a tadpole at firſt produced from ſpawn, and in its progreſs towards a frog, ſuch an animal, when full grown, if it bears the ſame proportion to its tadpole as thoſe in Europe do, muſt be of enormous ſize; for our full grown frogs exceed the tadpoles at leaſt 50 times.

FRONDESCENTIA, from *frons, a leaf*; the preciſe time of the year and month in which each ſpecies of plants unfolds its firſt leaves. All plants produce new leaves every year; but all do not renew them at the ſame time. Among woody plants, the elder and moſt of the honey ſuckles; among perennial herbs, crocus and tulip, are the firſt that puſh or expand their leaves. The time of ſowing the ſeeds decides with reſpect to annuals. The oak and aſh are conſtantly the lateſt in puſhing their leaves: the greateſt number unfold them in ſpring; the moſſes and firs, in winter. Theſe ſtriking differences with reſpect to ſo capital a circumſtance in plants as that of unfolding their leaves, ſeem to indicate that each ſpecies of plants has a temperature proper or peculiar to itſelf, and requires a certain degree of heat to extricate the leaves from their buds, and produce the appearance in queſtion. This temperature, however, is not ſo fixed or conſtant as it may appear to a ſuperficial obſerver. Among plants of the ſame ſpecies, there are ſome more early than others; whether that circumſtance depends, as it moſt commonly does, on the nature of the plants, or is owing to differences in heat, expoſure, and ſoil. In general, it may be affirmed, that ſmall and young trees are always earlier than larger or old ones. The puſhing of the leaves is likewiſe accelerated or retarded according to the temperature of the ſeaſon; that is, according as the ſun is ſooner or later in diſpenſing that certain degree of heat which is ſuitable to each ſpecies.

FRONT, the forehead, or that part of the face above the eyebrows. The word is formed of the Latin, *frons*: and that from the Greek Φρονειν, *to think, perceive*; of Φρην, *mens, the mind, thought*.

Front is alſo uſed where ſeveral perſons, or things, are ranged ſide by ſide, and ſhew their *front*, or foreparts. Front, in perſpective, a projection or repreſentation of the face, or fore part of an object, or of that part directly oppoſite to the eye; called alſo, and more uſually, Orthography.

FRONTIER, the border, confine, or extreme, of a kingdom, or province; which the enemies find in front when they would enter the ſame. Thus we ſay, a *frontier* town, *frontier* province, &c. *Frontiers* were anciently called *marches*.

FRONTISPIECE, in architecture, the portait or principal face of a building. See Architecture.

Frontispiece is alſo uſed to ſignify an ornament fronting the title page of a book, which ſhould expreſs the ſubject treated of, either allegorically, or literally, as in the inſtance of the *Frontiſpiece* prefixed to this Work.

FROST, in phyſiology, ſuch a ſtate of the atmoſphere as occaſions the congelation or freezing of water and other fluids. See Congelation.

Under the articles Cold, Congelation, Evaporation, Fluidity, &c. it is ſhewn, that water and other fluids are capable of containing the element of fire, or heat, in two very different ſtates. In the one, they ſeem to imbibe the fire in ſuch a manner, that it eludes all the methods by which we are accuſtomed to obſerve it, either by our ſenſation of feeling, or the thermometer; in the other, it manifeſts itſelf obviouſly to our ſenſes, either by the touch, the thermometer, or the emiſſion of light.

In the firſt of theſe ſtates, we call the body cold; and are apt to ſay that this coldneſs is occaſioned by the abſence of heat. But this manner of expreſſing ourſelves is certainly improper: for, even thoſe fluids which are coldeſt to the touch, contain a vaſt deal of heat. Thus, vapour, which is colder to the touch than the water from which it was raiſed, contains an immenſe quantity of fire, even more than ſufficient to heat it red hot. The like may be ſaid of common ſalt, and ſnow, or ice. If a quantity of each of theſe ſubſtances is ſeparately reduced to the degree of 28 or 30 of Fahrenheit's thermometer, upon mixing them together, the heat which would have raiſed the thermometer to the degree abovementioned, now enters into the ſubſtance of them in ſuch a manner that the mercury falls down to 0. Here an exceſſive degree of cold is produced, and yet we are ſure that the ſubſtances contain the very ſame quantity of heat that they formerly did: nay, they will even ſeem exceedingly cold, when they moſt certainly contain a great deal more heat than they originally did: for they abſorb it from all bodies around them: and if a ſmall veſſel full of water is put in the middle of ſuch mixture, it will in a ſhort time be full of ice. It appears, therefore, that our ſenſes, even when aſſiſted by thermometers, can only judge of the ſtate in which the element of fire is with relation to the bodies around us, without regard to the quantity contained in them. Thus, if heat flows from any part of our body into any ſubſtance actually in contact with it, the ſenſation of cold is excited, and we call that ſubſtance cold; but if it flows from any ſubſtance into our body, the ſenſation of heat is excited, and we call that ſubſtance hot, without regard to the abſolute quantity contained in either caſe. See Heat.

Of all known ſubſtances, the atmoſphere either abſorbs or throws out heat with the moſt remarkable facility; and in one or other of theſe ſtates it always is with reſpect to the ſurface of the earth, and ſuch bodies as are placed on or near it: for theſe, properly ſpeaking, have no temperature of their own, but are entirely regulated by that of the atmoſphere. When the air has been for ſome time abſorbing the heat from terreſtrial bodies, a froſt muſt be the undoubted conſequence, for the ſame reaſon that water freezes in a veſſel put into a freezing mixture; and were this abſorption to continue for a length of time, the whole earth would be converted into a frozen maſs. There are, however, certain powers in nature, by which this effect is always prevented; and the moſt violent froſt we can imagine, muſt always as it were defeat its own purpoſes, and end in a thaw. To underſtand this ſubject, we muſt obſerve, 1. In that ſtate of the atmoſphere which we denominate froſt, there is a moſt intimate union between the air and the water it contains; therefore froſty weather, except in very high latitudes, is generally clear.

2. When ſuch an union takes place, either in winter or ſummer, we obſerve the atmoſphere alſo inclined to abſorb heat, and conſequently to froſt. Thus in clear ſettled weather, even in ſummer, though the day may be exceſſively hot by reaſon of the continued ſunſhine, yet the mornings and evenings are remarkably cold, and ſometimes even diſagreeably ſo.

3. The air being, therefore, always ready in the time of froſt, or in clear weather, to abſorb heat from every ſubſtance which comes into contact with it, it follows that it muſt alſo abſorb part of that which belongs to the vapours contained in it.

4. Though vapour is capable of becoming much colder than water without being frozen, yet by a continued abſorption it muſt at laſt part with its latent heat, i. e. that which eſſentially conſtitutes it vapour; and without which it is no longer vapour, but water or ice. No ſooner, therefore, does the froſt arrive at a certain pitch, than the vapours, every where diſperſed through the air, give out their latent heat: the atmoſphere then becomes clouded; the froſt either totally goes off, or becomes milder by reaſon of the great quantity of heat diſcharged into the air; and the vapours deſcend in rain, hail, or ſnow, according to the particular diſpoſition of the atmoſphere at the time.

5. Even in the polar regions, where it may be thought that the froſt muſt increaſe beyond meaſure, there are alſo natural means for preventing its running to extremes. The principal cauſe here is, the mixture of a great quantity of vapours from the more temperate regions of the globe with the air in thoſe dreary climates. It is well known, that aqueous vapour always flies from a warm to a colder place. For this reaſon, the vapours raiſed by the ſun in the more temperate regions of the earth, muſt continually travel northward and ſouthward in great quantities. Thus they furniſh materials for thoſe immenſe quantities of ſnow and ice which are to be found in the neighbourhood of the poles, and which we cannot imagine the weak influence of the ſun in theſe parts capable of raiſing. It is impoſſible that a quantity of vapour can be mixed with froſty air, without communicating a great deal of heat to it; and thus there are often thaws of conſiderable duration in thoſe climates where, from the little influence of the ſun, we ſhould ſuppoſe the froſt would be perpetual.

6. We may now account without ſome probability for the uncertain duration of froſts. In this country they are ſeldom of a long continuance; becauſe the vapours raiſed from the ſea with which our iſland is ſurrounded, perpetually mix with the air over the iſland, and prevent a long duration of the froſt. For the ſame reaſon, froſts are never of ſuch long duration in maritime places on the continent, as in the inland ones. There is nothing, however, more uncertain than the motion of the vapours with which the air is conſtantly filled, and therefore it is impoſſible to prognoſticate the duration of a froſt with any degree of certainty. In general

we may always be certain, that if a quantity of vapour is accumulated in any place, no intenſe froſt can ſubſiſt in that place for any length of time; and by whatever cauſes the vapours are driven from place to place, by the ſame cauſes the froſts are regulated throughout the whole world. See **Thaw**, **Vapour**, &c. In the northern parts of the world, even ſolid bodies are liable to be affected by froſt. Timber is often apparently frozen, and rendered exceedingly difficult to ſaw. Marle, chalk, and other leſs ſolid terreſtrial concretions, will be ſhattered by ſtrong and durable froſts. Metals are contracted by froſt: thus, an iron tube, 12 feet long, upon being expoſed to the air in a froſty night, loſt two lines of its length. On the contrary, froſt ſwells or dilates water near one tenth of its bulk. Mr. Boyle made ſeveral experiments with metalline veſſels, exceedingly thick and ſtrong; which being filled with water, cloſe ſtopped, and expoſed to the cold, burſt by the expanſion of the frozen fluid within them. Trees are frequently deſtroyed by froſt, as if burnt up by the moſt exceſſive heat; and in very ſtong froſts, walnut trees, aſhes, and even oaks, are ſometimes ſplit and cleft, ſo as to be ſeen through, and this with a terrible noiſe, like the exploſion of fire-arms.

Water alſo, expoſed to the cold air in large veſſels, always freezes firſt at the upper ſurface, the ice gradually increaſing and thickening downwards: for which reaſon, frogs retire in froſty weather at the bottom of ditches; and it is ſaid that ſhoals of fiſh retire in winter to thoſe depths of the ſea and rivers, where they are not to be found in ſummer. Water, like the earth, ſeems not diſpoſed to receive any very intenſe degree of cold at a conſiderable depth or diſtance from the air. The vaſt maſſes of ice found in the northern ſeas being only many flakes and fragments which, ſliding under each other, are, by the congelation of the intercepted water cemented together.

In cold countries, the froſt often proves fatal to mankind; not only producing gangrenes, but even death itſelf. Thoſe who die of it have their hands and feet firſt ſeized, till they grow paſt feeling it; after which the reſt of their bodies is ſo invaded, that they are taken with a drowſineſs, which, if indulged, they awake no more, but die inſenſibly. But there is another way whereby it proves mortal, viz. by freezing the abdomen and viſcera, which on diſſection are found to be mortified and black.

As an inſtance of the dreadful effects of extreme cold on the human body, we ſhall give the following account extracted from the deſcription of the Iſland of Terra del Fuego, from 53 to 55° ſouth latitude, in **Bankes**'s Syſtem of **Geography**, vol. I. p. 537 and 538.—"When Mr. Banks, Dr. Solander, and other gentlemen, with their attendants and ſervants, ſet out from the ſhip, with a few of the men, to penetrate as far as they could into the country, and return at night, the hills, when viewed at a diſtance, ſeemed to be partly a wood, partly a plain, and above them a bare rock. Mr. Banks hoped to get through the wood, and made no doubt but that beyond it he ſhould, in a country which no botaniſt had ever yet viſited, find plants which would abundantly compenſate his labour. Mr. Banks and the other gentlemen went on, and in a ſhort time reached the ſummit. As botaniſts, they were abundantly gratified by finding a variety of plants, which, with reſpect to the Alpine plants in Europe, are exactly what thoſe plants are, with reſpect to ſuch as grow in the plain. The cold was now become more ſevere, and the ſnow blaſts more frequent; the day alſo was ſo far ſpent, that it was found impoſſible to get back to the ſhip before the next morning. To paſs the night on ſuch a mountain, in ſuch a climate, was not only comfortleſs, but dreadful: it could not, however, be avoided, and they were to provide for it as well as poſſible."

Dr. Solander, who had more than once croſſed the mountains which divide Sweden from Norway, well knew that extreme cold produces a ſleepineſs that is almoſt irreſiſtible, and therefore conjured the company to keep moving, however painful it might be. His words were, "Whoever ſits down will ſleep, and whoever ſleeps will wake no more." Though thus admoniſhed, the cold became ſuddenly ſo intenſe as to produce the effects moſt dreaded. Dr. Solander himſelf was the firſt who found the inclination, againſt which he had warned others as irreſiſtible, and inſiſted upon being ſuffered to lie down. Mr. Banks in vain remonſtrated; he lay down upon the ground, though it was covered with ſnow, and it was with great difficulty his friend could keep him from ſleeping. Richmond alſo, one of the black ſervants, began to linger, having ſuffered from the cold in the ſame manner. Mr. Banks, therefore, ſent five of the company, among whom was Mr. Buchan, forward, to prepare a fire at the firſt convenient place; while himſelf, with four others, remained with the Doctor and Richmond, whom partly by perſuaſion and entreaty, and partly by force, they brought on; but when they had got through the greateſt part of the birch and ſwamp, they both declared they could go no farther. Mr. Banks again entreated and expoſtulated, but without effect. When Richmond was told that if he did not go on he would be frozen to death in a ſhort time, he anſwered, that he deſired nothing but to lie down and die. Doctor Solander did not ſo explicitly renounce his life: he ſaid he was willing to go on, but that he muſt firſt take ſome ſleep, notwithſtanding his former declaration that whoever ſlept would wake no more.

As it was impoſſible to carry them, and there was no remedy, they were both ſuffered to ſit down on the ground, and, in a few minutes, they fell into a profound ſleep. Soon after ſome of thoſe who had been ſent forward returned with the welcome news that a fire was kindled about a quarter of a mile farther on. Mr. Banks then happily awakened Dr. Solander, who, though he had not ſlept five minutes, had almoſt loſt the uſe of his limbs; and the muſcles were ſo ſhrunk, that his ſhoes fell from his feet. He conſented to go forward with ſuch aſſiſtance as could be given him: but all attempts to relieve poor Richmond were ineffectual. Mr. Banks, therefore, left his other black ſervant, and a ſeaman, who ſeemed to have ſuffered leaſt from the cold, to look after him, promiſing that as ſoon as two others ſhould be ſufficiently warmed, they ſhould be relieved. Mr. Banks, with great difficulty, got the Doctor to the fire; and ſoon after ſent two of the people who had been refreſhed, hoping that, with the aſſiſtance of thoſe who had been left behind, they would be able to bring Richmond, though it might ſtill be impoſſible to awake him. In about half an hour they had the mortification to ſee the two men return alone. They informed them, that, after the moſt minute ſearch, they could neither find Richmond, or thoſe who had been left with him; and that though they had repeatedly ſhouted, no voice had replied. Another fall of ſnow came on, and continued inceſſantly for two hours; ſo that all hope of ſeeing them again, at leaſt alive, was given up; but in ſome time, to the general joy of the company at the fire, a ſhouting was heard at a diſtance. Mr. Banks, with four others, immediately went out, and found the ſeaman with juſt ſtrength enough to ſtagger along, and call for aſſiſtance. Mr. Banks having ſent him immediately to the fire, proceeded, by his directions, in ſearch of the other two, whom he ſoon after found. Richmond was upon his legs, but not able to put one foot before the other. His companion was lying upon the ground, as ſenſeleſs as a ſtone. The whole company was now called from the fire, and an united attempt was made to carry them to it, but without effect. The night was extremely dark, the ſnow very deep; ſo that finding it very difficult to make way through the buſhes and bogs themſelves (all getting many falls in the attempt) the only alternative was to make a fire on the ſpot: but the ſnow that had fallen, and was ſtill falling, beſides what was momentarily ſhaken in flakes from the trees, rendered it equally impracticable to kindle one there, or to bring any part of that which had been kindled in the wood thither. They were reduced to the melancholy neceſſity of leaving the unhappy wretches to their fate, having previouſly made them a bed of boughs from the trees, and ſpread a covering of the ſame kind over them to a conſiderable height. After ſuffering the region of the cold and ſnow near an hour and a half, ſome of the reſt began to loſe their feeling, and Briſcoe, another of Mr. Banks's ſervants, was ſo ill, that it was apprehended he muſt die before he could get to the fire. However, at length they reached the fire, and paſſed the night in a ſituation dreadful in itſelf, and rendered more ſo by the remembrance of paſt ſeverities, and the uncertainty of what was to come. They were twelve in number who had ſet out in health and ſpirits. Of theſe, two were ſuppoſed to be already dead; a third was ſo bad, that it was doubtful whether he would be able to proceed in the morning; and a fourth, Mr. Buchan, was in danger of the return of his fits, from freſh fatigues after ſo uncomfortable a night. They were a long day's journey diſtant from the ſhip, through pathleſs woods, in which they might be bewildered till overtaken by the enſuing night; and not having prepared for a journey of more than eight or ten hours, their whole ſtock of remaining proviſion was a vulture, which they happened to ſhoot when they were out, and which, if equally divided, would not afford each of them half a meal; and they knew not how much more they might ſuffer from the cold, as the ſnow ſtill continued to fall; a dreadful proof of the rigour of the climate, as it was now the midſt of ſummer in this part of the world; and every thing might be dreaded from a phœnomenon which in the correſponding ſeaſon, is unknown even in Norway and Lapland. The only object viſible at day-break was ſnow which ſeemed to lie as thick upon the trees as upon the ground; and the blaſts returned ſo frequently, and with ſuch violence, that they found it impoſſible for them to ſet out. The knew not how long this might laſt, and had but too much reaſon to apprehend, that it would confine them in that deſolate foreſt till they periſhed with hunger and cold. A dawn of hope ſucceeded theſe terrific apprehenſions; for, about ſix o'clock in the morning, they diſcovered the place of the ſun, through the clouds, which were become thinner, and began to break way. Their firſt care was to know whether the poor wretches they had been obliged to leave among the buſhes were yet living: for this purpoſe they diſpatched three of the company, who ſoon after returned with the melancholy news of their death. They were now, however, preſſed with the calls of hunger, to which every other conſideration muſt give way. They therefore came to an unanimous reſolution, before they ſet forward, to eat their vulture, which was accordingly ſkinned; and it being thought beſt to divide it before it was fit to be eaten, is was cut into ten portions, and every man cooked his own as he thought proper. After this ſlender meal, which furniſhed about three mouthfuls each, they prepared to ſet out; but it was ten o'clock before the ſnow was ſo far diſſolved as to render their progreſs practicable. Having proceeded about three hours, they were moſt agreeably ſurprized to find themſelves upon the beach, and much nearer the ſhip than they had reaſon to expect. Upon reviewing their track from the veſſel, they perceived that, inſtead of aſcending the hill in a line ſo as to penetrate into the country, they had made almoſt a circle round it. On their arrival on board, they congratulated each other. and were congratulated by the crew in general, with an extacy of joy that can only be conceived by ſuch as have been expoſed to equal danger; and Captain Cook, to the honour of his humanity, obſerves, that, as he ſuffered the greateſt anxiety from their not returning in the evening of the day on which they ſet out, he participitated in no ſmall degree of the general joy."

Hoar Frost, a cold moiſt vapour, that is drawn up a little way into the air, and in the night falls again on the earth, where it is congealed into icy cryſtals of various figures. Hoar froſt, therefore, is nothing but dew turned into ice by the coldneſs of the air.

Melioration of Aromatic Spirits by Frost. Mr. Baume obſerves, that aromatic ſpirituous waters have leſs ſcent when new diſtilled than after they have been kept about ſix months: and he found that the good effects of age was produced in a ſhort time by means of cold; and that, by plunging quart bottles of the liquor into a mixture of pounded ice and ſea ſalt, the ſpirit, after having ſuffered for ſix or eight hours the cold hence reſulting, proves as grateful as that which hath been kept many years. Simple waters alſo, after having been frozen, prove far more agreeable than they were before. Geoffroy takes notice of this melioration by froſt. *Hiſt. Acad.* 1713.

FROTH, a white, light ſubſtance, formed on the ſurface of fluids, by vehement agitation. Froth conſiſts wholly of little ſpherules, or globules; and, accordingly, may be defined an aſſemblage of aqueo-aerial bubbles.

Froth-*Spit* or *Cuckow-Spit*, a name given to a white froth, or ſpyme, very common in the ſpring and firſt months of ſummer, on the leaves of certain plants, particularly on thoſe of the common white field-lychnis or catch-fly, thence called by ſome *ſpatling poppy*. All writers on vegetables have taken notice of this froth, though few have underſtood the cauſe or origin of it till of late. It is formed by a little leaping animal, called by ſome the *flea graſs-hopper*, by applying its anus cloſe to the leaf, and diſcharging thereon a ſmall drop of white viſcous fluid, which, containing ſome air in it, is ſoon elevated into a ſmall bubble: before this is well formed, it depoſits ſuch another drop; and ſo on, till it is every way overwhelmed with a quantity of theſe bubbles, that form the white froth which we ſee. Within this ſpume it is ſeen to acquire four tubercles on its back, wherein the wings are incloſed: theſe burſting, from a reptile it becomes a winged animal: and thus, rendered perfect, it flies to meet its mate, and propagate its kind. It has an oblong, obtuſe body, and a large head with ſmall eyes. The external wings, for it has four, are of a duſky brown colour, marked with two white ſpots: the head is black. It is a ſpecies of *Cicada*.

FRUCTESCENTIA, (from *fructus*, fruit,) comprehends the preciſe time in which, after the fall of the flowers, the fruits arrive at maturity, and diſperſe their ſeeds. In general, plants which flower in ſpring, ripen their fruits in ſummer, as rye; thoſe which flower in ſummer, have their fruits ripe in autumn, as the vine; the fruit of autumnal flowers ripens in winter, or the following ſpring, if kept in a ſtove or otherwiſe defended from exceſſive froſts. Theſe froſts, ſays M. Adanſon, are frequently ſo pernicious and violent as to deſtroy the greateſt part of the perennial plants of Virginia and Miſſiſſippi, that are cultivated in France, even before they have exhibited their fruit. The plants which flower during our winter, ſuch as thoſe of the Cape of Good Hope, ripen their fruit in ſpring in our ſtoves.

FRUCTIFICATION *of Plants*. Fructification is defined by Linnæus to be the temporary part of a vegetable appropriated to generation, terminating the old vegetable, and beginning the new. It conſiſts of the following ſeven parts; viz. the *calyx*, *corolla*, *ſtamen*, *piſtillum*, *pericarpium*, *ſemen or ſeed*, and *receptaculum*. See Syſtem of Botany, Sect. III. Plate III.

FRUIT, in its general ſenſe, includes whatever the earth produces for the nouriſhment and ſupport of animals; as herbs, grain, pulſe, hay, corn, flax, and every thing expreſſed by the Latins under the name *fruges*.

The fruit in the Linnæan ſyſtem is one of the parts of fructification, and is diſtinguiſhed into three parts, viz. the *pericarpium*, *ſeed*, and receptacle, or *receptaculum ſeminum*. The *fruit* is defined by Jungius and former botaniſts to be an annual part of the plant, which adheres to the flower and ſucceeds it; and, after attaining maturity, ſeparates or detaches itſelf from the parent plant; and, being commodiouſly lodged in the boſom of the earth, gives birth to a new vegetable. This definition is ſufficiently accurate, and ſo perſpicuous, that it requires no illuſtration whatever. We ſhall only obſerve, that, in its vulgar acceptation, the word fruit is expreſſive, not of the ſeeds, which are doubtleſs the eſſence of every fruit; but of the caſe or veſſel in which they are contained. Thus, when we ſpeak of the fruit of an apple-tree, we always mean the luſcious pulp which enfolds the ſeeds; although that, in ſtrict propriety, is only the cover of the fruit. In cutting open an apple tranſverſly, it will be found to conſiſt of four parts; viz. 1. A ſkin, or *cortex*, which is only a production of the ſkin, or outer bark, of the tree. 2. A *parenchyma*, or pulp; which is an expanſion and intumeſcence of the inner bark of the tree. 3. Fibres, or ramifications, of the woody part of the tree, diſperſed throughout the parenchyma. 4. The core, which is the produce of the pith, or medulla, of the plant, indurated and ſtrengthened by twigs of the wood and fibres, inoſculated therewith: it ſerves to furniſh a cell, or lodge, for the kernels; filtrates the juice of the parenchyma; and conveys it, thus prepared, to the kernel.—As to the uſe of fruits, beſide the pleaſure and advantage they afford men, &c. they are of ſervice in guarding, preſerving, and feeding the ſeed incloſed; in filtrating the coarſer, more earthy, and ſtony parts of the nutritious juice of the plant, and retaining them to themſelves; and ſending none to the ſeed but the pooreſt, moſt elabòrated, and ſpirituous parts, for the ſupport and growth of the tender, delicate embryo, or plantule, contained therein. So that the *fruit* does the ſame office to the ſeed, that the leaves of the flower do to the *fruit*. The uſe of *fruits*, with us might, under proper regulations, be rendered much more extenſive than it is. Many fruits which do hurt when eaten raw, would make wines equal in flavour to many of thoſe now obtained at great prices from abroad; and lands which will not bear corn, yet will bear trees and ſhrubs producing ſuch *fruits*; and the conſequence of this method of culture would be, that much ground, at preſent lying waſte, would be occupied, and great employment found for the numerous poor of ſome of our counties, where the quantities of waſte land are proportionably ſo great, that there is not employment for the people of one half of the county. Cherries properly managed make an excellent wine, and that in very large quantities; and plums alſo make a very agreeable kind, but that it has an auſtereneſs, which muſt be taken off by mixing a little ſugar with it when in the glaſs, not before it is drawn off. A coarſe plum, ſomewhat larger than a damſon, is the beſt kind for this wine. There is a ſort of plum that grows wild in ſome of our hedges. It will ſucceed on any ground, the pooreſt that can be imagined, and it produces a great abundance of *fruit*. The wine that is made from it is of a very conſiderable ſtrength, and affords a pleaſant brandy by diſtillation in conſiderable quantities. Our common garden currants afford very agreeable wine; and our gooſeberries are not ſecond to any thing. All theſe produce *fruit* in great abundance; and the planting and taking care of them is very cheap, and the operation very eaſy. Phil. Tranſ. N° 124.

Fruits are diſtinguiſhed, by gardeners, into *ſtone-fruit*, and *kernel-fruits*; *ſummer-fruit*, and *winter-fruit*, *wall-fruit*, and *dwarf-fruit*, &c. M. Quintinie obſerves, that cold, heavy, moiſt lands, produce the faireſt and largeſt fruit, but the hotter, drier, and lighter, the more delicious and rich-taſted.

Bread Fruit. See Bread *Tree*.

Fruit-*Flies*, a name given by gardeners, and others, to a ſort of ſmall black *flies*, found in vaſt numbers among *fruit*-trees, in the ſpring-ſeaſon, and ſuppoſed to do great injury to them. Theſe are a ſpecies of ſmall black fly. Mr. Lewenhoeck preſerved ſome of them for his microſcopical obſervations. He found that they did not live longer than a day or two, but that the females in this time uſually laid a great number of longiſh eggs. The gardeners who ſuppoſe that theſe flies wound the leaves of the trees, are miſtaken; it is true that they feed on their juices, but they have no weapons with which to extract this themſelves; they feed on ſuch as is naturally extravaſated, and when there is not enough of this for their purpoſe, they haunt thoſe places where the *pucerons* reſort, and feed on the juices which theſe little creatures extravaſate by means of the holes they bore in the leaves with their trunks. Theſe pucerons are a ſmall ſort of inſect very common on our *fruit*-trees, and other plants and trees; they are of a greeniſh colour, and are commonly called tree-lice. Philoſ. Tranſ. N° 262.

Fruit-*Stones*. The miſchiefs ariſing from the bad cuſtom of people ſwallowing the ſtones of plums and other *fruit* are very great. The Philoſophical Tranſactions give us an account of a woman who ſuffered violent pains in her bowels for thirty years, returning once in a month or leſs. At length a ſtrong purge being given her, the occaſion of all theſe complaints was driven down to the anus, where it gave a ſenſation of ſtoppage and diſtenſion, and produced a continual deſire of going to ſtool, but without voiding any thing. On the aſſiſtance of a careful hand in this caſe, there was taken out with a forceps an oblong ball of an oval figure, of about ten drams weight, and meaſuring five inches in circumference; this had cauſed all the violent fits of pain ſhe had been ſo many years afflicted with, and after the taking it out ſhe became perfectly well. The ball extracted looked like a ſtone, and felt very hard, but it ſwam in water; on cutting it through with a knife, there was found in the centre of it a plum-ſtone, round which ſeveral coats of this tough and hard matter, reſembling a ſtone, had gathered. This ſufficiently ſhews the folly of that common opinion, that the ſtones of *fruits* are wholeſome. For though by nature the guts are ſo defended by their proper mucus, that people very ſeldom ſuffer by things of this kind, yet if we conſider the various circumvolutions of the guts, their valves and cells, and at the ſame time conſider the hair of the ſkins of animals we feed on, the wool or down on herbs and *fruit*, and the fibres, veſſels, and nerves of plants, which are not altered by the ſtomach, it will appear a wonder that inſtances of this ſort of miſchief are not much more frequent. Cherry-ſtones, ſwallowed in great quantities, have occaſioned the death of many people, and there have been inſtances even of the ſeeds of ſtrawberries, and kernels of nuts, collected into a lump in the guts, and cauſing violent diſorders, which could never be cured till they were carried off. Philoſ. Tranſ. N° 282. p. 1282.

Fruit-*trees* are diſtinguiſhed, like the *fruits* they bear, into wall *fruit*-trees, ſtandard *fruit* trees, &c. With regard to *fruit*-trees, Monſ. Quintinie obſerves, 1. That the cutting and trimming of young trees hinders them from quick bearing; though it contributes both to the beauty of the tree, and to the richneſs and flavour of the fruit. 2. That kernel *fruit*-trees come later to bear than ſtone *fruit*-trees; the term required by the firſt, before they arrive at a fit age for bearing, being, one with another, about four or five years; but, when they do begin, they bear in greater plenty than ſtone-*fruit*. 3. That ſtone-*fruits*, figs, and grapes, commonly bear conſiderably in three or four years; and bear full crops the fifth and ſixth years; and hold it for many years, if well ordered. 4. That *fruits*, in the ſame neighbourhood, will ripen a fortnight ſooner in ſome grounds, than in others of a different temperature. 5. That in the ſame country, hot or cold ſummers ſet conſiderably forwards, or put backwards, the ſame *fruit*. 6. That the *fruits* of wall-trees generally ripen before thoſe on ſtandards; and thoſe on ſtandards before thoſe on dwarfs. 7. That the *fruit* of wall-trees, planted in the ſouth and eaſt quarters, ripen about the ſame time; only thoſe in the ſouth earlier than thoſe in the eaſt; thoſe in the weſt are later by eight or ten days, and thoſe in the north by fifteen or twenty. For the planting, pruning, engrafting, &c. of *fruit*-trees, ſee Planting, Transplanting, Pruning, and Grafting. See alſo Orchard, Garden, and Nursery.

There is, in the Philoſophical Tranſactions, a method of making *fruits* and flowers grow in winter inſtead of ſummer, without the common way of doing it by heat. This method is to take up the trees with their roots in the ſpring-ſeaſon, juſt as they begin to ſhoot out their buds; let them be placed upright in a cellar, and ſtand there till the end of September following; then fit veſſels to them, and place the roots in them, covering them in a proper manner with earth, and bring them up into a common ſtove; water them at times with a ſolution of the bigneſs of a walnut of crude ſal armoniac in a quart of rain-water, and they will make their natural progreſs as in ſummer, and in the months of February or March following the *fruit* will be ripe, and as well taſted as if it had grown on them in the common way, and ripened at its natural ſeaſon. Philoſ. Tranſ. N° 282, p. 44. The ſuperfluous ſhoots from theſe trees muſt be pruned off at ſuch times of the year, when the trees are full of juice, and furniſhed for a farther ſupply; and by this means there will be no marks of the wounds, they will cloſe up ſo perfectly. The manner of producing pyramidal trees by ingrafting, is not only applicable to *fruit*-trees, but has been tried on oaks, limes, and roſes, with the ſame ſucceſs.

The Peterſbourg academy furniſhes us with two ſingular inſtances of *fruits* growing in an unnatural manner; one of thoſe in the fig-tree, the other in the apple-tree. In both theſe caſes, the *fruit*, inſtead of its common ſituation, was placed upon the trunk of the tree, with no branch or leaf near it, but only a ſhort pedicle for its ſupport. The inſtance of the fig-tree afforded three figs in a cluſter, the middle one of which withered, but the other two grew to their proper ſize, and were like the reſt of the figs on the ſame tree. The other inſtance of the apple-tree afforded only one ſingle *fruit*; but there was in it ſomething very ſtrange, or that appeared ſo, however, at firſt ſight; for the apples produced on the branches of the tree were of one kind, and this of another: The tree had been grafted, and all the *fruit* of the branches grew from the graft; this ſingle one, which ſtood upon the trunk of the tree below the graft, was of the ſpecies produced by the ſtock. This had doubtleſs been preceded by a flower, though unobſerved, and it could only be as it appeared, of the nature of the genuine *fruit* of the ſtock. All gardeners know, that the ſtock ſuffers no change from the graft; in both theſe caſes there was probably the rudiment of a branch where the ſingle *fruit* appeared, and every other part of it, except the bud of the *fruit* alone, had periſhed, while that arrived at its deſtined ſize and maturity. We have alſo an account in the Philoſophical Tranſactions, N° 385, of an apple-tree bearing a conſiderable quantity of *fruit* for many years together without bloſſoming.

FRUITERY, a place for the laying up and keeping of *fruit*. The *fruitery* ſhould be inacceſſible to any thing of moiſture, or even froſt.

FRUITFULNESS, the quality of bearing plenty of fruit, called alſo *fertility*, and *fecundity*.

FRUMENTACEOUS *Plants* are thoſe which produce geniculated or knotted ſtalks, with reed-like leaves; and whoſe ſeed growing in ſpikes or *jubæ*, is uſeful to make pultege, or bread. The word is formed from *frumentum*, a general name comprehending all ſorts of corn, or grain, for bread. Hence the Italians, who follow the Latins, uſe *grano* and *frumento* for the ſame. Wheat, barley, rye, millet, &c. are *frumentaceous* plants. Some authors uſe *frumentaceous* in a narrower ſenſe, reſtraining it to plants which bear a conformity to wheat, either in reſpect of their fruits, leaves, ears, or the like. But this ſeems founded on a miſtaken notion of *frumentum*, as if it denoted only *wheat*, which is rather the ſenſe of the word *triticum*.

FRUSTUM, in mathematics, a piece cut off or ſeparated from a body. Fruſtum of a pyramid or cone, is a part or piece thereof cut off, uſually by a plane parellel to the baſe.

FRUTEX, *a Shrub*. Shrubs, according to Linnæus, make a branch of the ſeventh family in the vegetable kingdom; and are diſtinguiſhed from trees, in that they come up without buds. But this diſtinction is not univerſal, though it be generally juſt with regard to thoſe of Europe. Nature hath made no abſolute diſtinction between trees and ſhrubs. *Frutex*, in its general acceptation, is a plant whoſe trunk is perennial, gemmiparous, woody, dividing and ſubdividing into a great number of branches. In ſhort, it is the epitome of a tree exemplified in the roſe-buſh.

FUCUS, in botany, a genus of ſubmarine plants, belonging to the cryptogamia claſs. The fucus conſiſts of a tough matter, formed into a kind of leaves, which are flat and variouſly divaricated; and which have ſome appearance of fructification, in punctated tubercles, covering oblong veſicles, ſuppoſed by Linnæus to be male flowers; and ſmooth roundiſh veſicles, hollow and interwoven with filaments, which appear to him to be female flowers. There are 34 ſpecies of fucus, or ſea-wrack, many of them to be found on our coaſts. See the ſixth Plate of Botany, Claſs 24, Order III.

FUEL, in philoſophy, the *pabulum* of *fire*, or whatever receives and retains fire, and is conſumed, or rendered inſenſible thereby. It is a known truth, that *fuel* cannot conſume by means of heat alone, without the admiſſion of freſh air, and this is no way more clearly proved, than by this eaſy experiment. Let a ſtrong cylinder of iron, hollow within, be fitted with a firm ſcrew at each end; in the cavity of this cylinder incloſe a long piece of charcoal, and then ſcrew up both the ends faſt, and place the whole in a ſtrong fire; let it continue there for ſeveral hours; and when it is taken out and cooled, open it, and the piece of charcoal will be found ſtill black, in its own form, and no way apparently altered or diminiſhed. It is plain from this, that the conſumption of *fuel* depends upon the rarefaction, diſlodgment, briſk agitation, and diſcharge of its inflammable vapour, by means of freſh air: and hence we have the reaſon of the known rule of extinguiſhing fires by ſmothering them.

FUGITIVE, *Refugee*, a perſon obliged to fly his country, or remove from a place where he had ſome abode or eſtabliſhment, on account of his crimes, debts, or on other occaſions.

Fugitive *Pieces*, among the learned, denote thoſe little compoſitions which are printed on looſe ſheets, or half ſheets; thus called, becauſe eaſily loſt, and ſoon forgot.

FUGUE, of *fuga, flight*, in muſic, is when the different parts of a muſical compoſition follow each other, each repeating what the firſt had performed.

Single, or *Simple* Fugue, is ſome point conſiſting of 4, 5, 6, or any other number of notes, begun by one ſingle part, and then ſeconded by a third, fourth, fifth, and ſixth part, if the compoſition conſiſts of ſo many, repeating the ſame or ſuch-like notes; ſo that the ſeveral parts follow, or come in, one after another, in the ſame manner, the leading parts ſtill flying before thoſe which follow.

Double Fugue, is when two or more different points move together in a *fugue*, and are alternately interchanged by the ſeveral parts.

FULICA, the *Coot*, in ornithology, according to Linnæus, the 51ſt genus, and belonging to the fourth order called *Grallæ*. But Latham in his improved arrangment makes it the 78th genus, and the 8th order. For the claſſification, ſee the Syſtem. For the repreſentation, ſee Plate V. It has a convex bill, with the upper mandible fornicated over the lower at the edge; the lower mandible is gibbous behind the tip. The forehead is bald; and the feet have four toes, a little lobated. There are four ſpecies.

1. The *atra*, or *common coot*, hath a bald forehead, a black body, and lobated toes. They frequent lakes and ſtill rivers; making their neſt among the ruſhes, with graſs, reeds, &c. floating on the water, ſo as to riſe and fall with it. They lay five or ſix large eggs, of a dirty whitiſh hue, ſprinkled over with minute deep ruſt-coloured ſpots; and it is ſaid, that ſometimes they will lay 14 or more eggs. The young when juſt hatched are very deformed, and the head mixed with a red coarſe down, In winter they often repair to the ſea, and the channel near Southampton is ſometimes obſerved almoſt covered with them. They are often brought to that market, where they are expoſed to ſale without their feathers, and ſcalded like pigs.

2. The *chloropus*, or *common gallinule*, hath a bald forehead, and toes without webs. It gets its food on graſſy banks, and borders near freſh waters, and in the very waters if they be weedy. It builds upon low trees and ſhrubs by the water ſide; breeding twice or thrice in a ſummer; and, when the young are grown up, drives them away to ſhift for themſelves. They lay ſeven eggs of a dirty white, thinly ſpotted with ruſt colour. This bird ſtrikes with its bill like a hen, and in the ſpring has a ſhrill call, In flying, it hangs down its legs; in running, it often flirts up its tail, and ſhews the white feathers. We may obſerve, that the bottoms of its toes are ſo very flat and broad (to enable it to ſwim)

that it ſeems to be the bird which connects the cloven footed aquatics with the next tribe, viz. the fin toed.

3. The *fulica* with a bald forehead, a violet coloured body, and toes without webs, is the purple water hen of Edwards; and it inhabits Aſia and America. 4. The *fulica* with a carunculated head, a variegated body, ſpinous ſhoulders, and toes without webs; but the nail on the hinder toe is exceeding long. It is the ſpur-winged water hen of Edwards, and is an inhabitant of South America. The nail on the hind toe is ſtrait, and longer than a man's finger. The pollex reſts upon one joint, and the wings are green.

FULIGINOUS, an epithet applied to a thick ſmoke, or vapour, replete with ſoot or other craſs matter. The word is formed from the Latin *fuligo, ſoot*; and is rarely uſed but when joined with vapour. In the firſt fuſion of lead, there exhales a great deal of fuliginous vapour, which, retained and collected, makes what we call *lithargy*. *Lamp black* is what is gathered from the *fuliginous* vapours of pines, and other reſinous woods, when burnt. Some phyſicians talk of *fuliginous* vapours emitted from the ſpleen to the brain, which they will have to be the cauſe of the hypochondriac and hyſteric diſorders; thence called the *vapours*, and by ſome the *ſpleen*.

FULL is variouſly uſed, in oppoſition to empty, narrow, confined, &c. The Carteſians hold, that the univerſe is *full*, i. e. that every part or point has matter in it. When the body is *full* of humours it ſhould be purged.

FULLER, a workman employed in the manufactories, to full, mill, or ſcour cloths, rateens, ſerges, and other woollen ſtuffs, by means of a mill, to render them thicker, and more compact and durable.

FULLERS *Earth, ſmectis*, or *cimolia purpuraſcens*, is a hard, denſe marle, moderately heavy, of a very compact and regular texture, of a rough or dry appearance, though, when cut or ſcraped, is of a very ſmooth, unctuous, and glaſſy ſurface. It ſerves to ſcour cloths, ſtuffs, &c. and imbibe the tar employed in the external diſtemperatures of ſheep, and all the greaſe and oil, and other unctuous ſubſtances, neceſſarily uſed in the preparing, dreſſing, &c. of the wool. *Fullers-earth* is dug in great plenty out of certain pits near Brick-hill, in Staffordſhire; alſo near Ryegate, in Surry; near Maidſtone, in Kent; near Nutley and Petworth, in Suſſex. But the greateſt quantity and the fineſt earth of this kind in the world, is dug in the pits at Wavendon, near Woburn, in Bedfordſhire. The ſtrata in theſe pits lie thus: from the ſurface to the depth of ſix yards, there are ſeveral layers or beds of ſand, all reddiſh, but ſome lighter coloured than others. Under theſe there is a thin ſtratum of a ſand ſtone, which they break through, and then for the depth of about ſeven or eight yards you have ſand again, and then there is the fullers earth.

It is abſolutely neceſſary to the well dreſſing of cloth: and hence foreigners, though they can procure wool to be clandeſtinely exported out of the kingdom, can never reach to the perfection of the Engliſh cloths, &c. without *fullers*-earth, which is very plentiful in England, and excels that of other countries in quality as much as in quantity and cheapneſs. For this reaſon it is made a contraband commodity; and the export made equally criminal with that of exporting wool. Abroad they make uſe of urine, in lieu of *fullers* earth. This earth abounds much in the vegetative ſalt which promotes the growth of plants, and is therefore reckoned by ſir H. Plat, and others, great improvers of land. When mixed with vinegar, it diſperſes pimples, checks inflammations, and cures burns.

FULLERY, a place where cloths, &c. are *fulled* or ſcoured. The term is principally underſtood of the fulling-mill.

FULLING, the art, or act of cleanſing, ſcouring, and preſſing cloths, ſtuffs, and ſtockings, to render them ſtronger, cloſer, and firmer: called alſo *milling*. The fulling of clothes, and other ſtuffs, is performed by a kind of water mill; thence called a *fulling*, or *ſcouring mill*. Theſe mills, excepting in what relates to the mill ſtones and hopper, are much the ſame with corn-mills. And there are even ſome which ſerve indifferently for both purpoſes; corn being ground, and cloths fulled, by the motion of the ſame wheel. Hence in ſome places, particularly France, the fullers are called *millers*; as grinding corn, and milling ſtuffs, at the ſame time. The principal parts of the *fulling mill* are, the wheel with its trundle; which gives motion to the tree or ſpindle, whoſe teeth communicate it to the peſtles, or ſtampers, which are hereby raiſed and depreſſed alternately, according as its teeth catch on, or quit, a kind of latch in the middle of each peſtle. The peſtles and troughs are of wood; each trough having at leaſt two, ſometimes three peſtles, at the diſcretion of the maſter, and according to the force of the ſtream of water. In theſe troughs are laid the cloths, ſtuffs, &c. intended to be *fulled*; then, letting the current of water fall on the wheel, the peſtles are ſucceſſively let fall thereon, and by their weight and velocity they ſtamp and preſs the ſtuffs very ſtrongly, which by this means become thickened and condenſed. In the courſe of the operation, they ſometimes make uſe of urine, ſometimes of *fullers* earth, and ſometimes of ſoap. To prepare the ſtuffs to receive the firſt impreſſions of the peſtle, they are uſually laid in urine; then in *fullers* earth and water: and laſtly in ſoap, diſſolved in hot water. Soap alone would do very well; but this is expenſive; though *fullers* earth, in the way of our dreſſing, is ſuperior to it; but then it muſt be firſt well cleared of all ſtones and grittineſs, which are apt to make holes in the ſtuff. As to urine, it is certainly prejudicial, and ought to be entirely diſcarded; not ſo much on account of its ill ſmell, as of its ſharpneſs and ſaltneſs; which is apt to render the ſtuffs dry and harſh.

FULMINATION, in the Romiſh canon law, a ſentence of a biſhop, official, or other eccleſiaſtic appointed by the pope; whereby it is decreed, that ſome bull, diſpenſation, or reſcript, ſent from the pope, ſhall be executed. *Fulmination* is alſo uſed for the denunciation, or execution, of a ſentence of *anathema*, made in public, with due ſolemnity.

FULMINATION, or FULGURATION, in chymiſtry, a vehement noiſe, or ſhock reſembling thunder, occaſioned by the ſuddon exploſion and inflammation of divers preparations; as *aurum fulminans*, &c. when ſet on fire.

FUMARIA, *fumitory*; a genus of the hexandria order, belonging to the diadelphia claſs of plants. There are a number of different ſpecies; all of them low, ſhrubby, and deciduous and evergreen plants, growing from two to ſix or ſeven feet high, adorned with ſmall ſimple leaves, and papilionaceous flowers of different colours. The moſt remarkable is the officinalis, or common fumitory; which grows naturally in ſhady cultivated grounds, and produces ſpikes of purpliſh flowers in May and June. It is very juicy, of a bitter taſte, without any remarkable ſmell. The medical effects of this herb are, to ſtrengthen the tone of the bowels, gently looſen the belly, and promote the urinary and other natural ſecretions. It is principally recommended in melancholic, ſcorbutic, and cutaneous diſorders, for opening obſtructions of the viſcera, attenuating and promoting the evacuation of viſcid juices. Frederic Hoffman had a very great opinion of it has a purifier of the blood; and aſſures us, that in this intention ſcarce any plant exceeds it. Cows and ſheep eat the plant; goats are found not fond of it; horſes and ſwine refuſe it.

FUMIGATION, in chymiſtry, a kind of calcination, when metals, or other hard bodies, are corroded, or ſoftened, by receiving certain fumes for that purpoſe. *Fumigation*, in medicine. By the ſubtile fumes that are inſpired as well as inhaled, into our bodies, much benefit or prejudice is produced, according to the nature of the matter, and the conſtitution into which it is received; as is evident from the palſies produced among workers in lead-mines, &c. and the benefits received in many caſes when the air is impregnated with ſalutary materials. Catarrhs and catarrhous coughs are relieved by fumes received with the breath; and by the ſame method, expectoration is aſſiſted in humoural aſthmas; and even ulcers in the lungs are ſaid to have been healed by this method. The advantage of mercurial fumigations in the cure of venereal ulcers is known to every practitioner.

Powder of FUMIGATION, was invented at Moſcow, in 1771, for preventing the infection of the plague. It is prepared of different degrees of ſtrength in the following manner: 1. Take leaves of juniper, juniper-berries pounded, ears of wheat, guaiacum wood pounded, or, if this cannot be had, the cones of pines or firs, of each ſix pounds; common ſalt-petre pounded, eight pounds; ſulphur pounded, ſix pounds; Smyrna tar or myrrh, or, inſtead of this, the common tar of pines and firs, two pounds; mix all theſe ingredients together, and they will produce a *pood* of the powder, of the firſt ſtrength. 2. Take ſouthernwood or mugwort, cut into ſmall pieces, five pounds; leaves of juniper, cut in the ſame manner, four pounds; juniper berries pounded, three pounds; common ſalt-petre pounded, four pounds; ſulphur pounded, two pounds and a half; Smyrna tar or myrrh, one pound and a half; mix theſe together, and they will yield half a *pood* of the powder of the ſecond ſtrength. The efficacy of the powder of *fumigation* was tried on ten malefactors under ſentence of death, who were confined three weeks in a lazarette, and expoſed in every poſſible way to the infection of the plague, and none of them were at all injured by it. Fumigation is alſo uſed for the act of making a ſuſpended body receive the fumes or ſteams of one or more other bodies, in order to calcine it, to correct it, or impart to it ſome new quality. Ceruſs is made by the *fumigation*, or vapour, of vinegar, gnawing and corroding plates of lead.

FUMIGATOR, formed of *fumus, ſmoke*, in ſurgery, an inſtrument uſed for injecting clyſters of the ſmoke of tobacco. Clyſters of this kind have been applied in the *iliac paſſion*, in the *hernia incarcerata*, and in other caſes of an obſtinate conſtipation, or obſtruction of the bowels; and as they are admirably adapted to excite the ſuſpended or extremely languid periſtaltic motion of the inteſtines, which are reckoned among the moſt irritable parts of the body, and are allowed to retain the vital influence longer than any other, they have been peculiarly ſerviceable in caſes of recovery from apparent death by drowning, &c.

FUNCTION, the act of fulfilling the duties of any employment. *Function*, being alſo applied to the actions of the body, is by phyſicians divided into vital, animal, and natural. The *vital* functions are thoſe neceſſary to life, and without which the individual cannot ſubſiſt; as the motion of the heart, lungs, &c. The *natural* functions are ſuch as it cannot ſubſiſt any conſiderable time without; as the digeſtion of the aliment, and its converſion into blood. Under *animal* functions are included the ſenſes of touching, taſting, &c. memory, judgment, and voluntary motion; without any or all of which an animal may live but not very comfortably. The animal-functions perform the motion of the body by the action of the muſcles; and this action conſiſts chiefly in the ſhortening the fleſhy fibres, which is called *contraction*, the principal agents of which are the arteries and nerves diſtributed in the fleſhy fibres. All parts of the body have their own functions, or actions, peculiar to themſelves. Life conſiſts in the *exerciſe* of theſe functions, and health in the *free* and *ready* exerciſe of them.

FUND, **Fundus**, a Latin term, uſed for the bottom of certain things; and particularly, of certain parts of the body.

Fundus *Uteri*, or *Bottom of the Womb*, is the body or principal part thereof; ſo called in contradiſtinction to the cervix, or neck; the oſculum, or mouth; and the vagina, or ſheath. See Syſtem of Anatomy, Part V. Sect. XII, and Plate X. *Fig*. 1. letter A.

Fund, in commerce, is uſed for the capital or ſtock of a merchant, company, or corporation; or the ſum of money that they put into trade. In this ſenſe we ſay abſolutely, the *funds*, the public *funds*, meaning the ſtock of the great companies, or corporations, as the Bank, South ſea, Eaſt India, &c.

Funds, in politics, are the taxes appropriated by parliament to the ſupport of civil government, and the payment of the principal and intereſt of money borrowed for public ſervices. The practice of funding was introduced by the Venetians and Genoeſe in the 16th century, and has been adopted ſince by moſt of the nations in Europe. Princes had often borrowed money, in former times, to ſupply their exigencies, and ſometimes mortgaged their territories in ſecurity: but theſe loans were generally extorted, and their payment was always precarious; for it depended on the good faith and ſucceſs of the borrower, and never became a regular burden on poſterity. The origin of funds is derived from the peculiar manners and circumſtances of modern Europe. Since the invention of gun powder, and the progreſs of commerce, the military occupation has become a diſtinct employment in the hands of mercenaries; the apparatus of war is attended with more expence; and the deciſion of national quarrels has often been determined by command of money, rather than by national bravery. Ambitious princes have therefore borrowed money, in order to carry on their projects with more vigour. Weaker ſtates have been compelled, in ſelf defence, to apply to the ſame reſource; the wealth introduced by commerce has afforded the means; the regularity of adminiſtration, eſtabliſhed in conſequence of the progreſs of civility, has increaſed the confidence of individuals in the public ſecurity; the complicated ſyſtem of modern policy has extended the ſcenes of war, and prolonged their duration; and the colonies eſtabliſhed by the mercantile nations have rendered them vulnerable in more points, and increaſed the expence of defending them.

When a greater ſum has been required for the annual expence, than could eaſily be ſupplied by annual taxes, the government have propoſed terms, to their own ſubjects, or foreigners, for obtaining an advance of money, by mortgaging the revenue of future years for their indemnification. This mortgage may either be for a limited period, or perpetual. If the ſum allotted annually for the benefit of thoſe who advance the money, be conſiderably greater than the intereſts of the ſums advanced, they may agree to accept of ſuch allowance, for a limited time, as a full equivalent. Thus, they may either agree for the caſual produce of the revenue aſſigned; or a fixed annuity for a greater or leſs number of years; or a life annuity to themſelves or nominees; or an annuity for two or more lives; or an annuity, with the benefit of ſurvivorſhip, called a *tontine*, in which ſcheme, the whole ſum to which the original annuitants were entitled continues to be diſtributed among the ſurvivors. When the ſum allotted to the creditors of the public is only equivalent to the intereſt of the money advanced, the grant muſt be perpetual, unleſs the debt be redeemed by payment of the principal. The eſtabliſhment of the funds was introduced in Britain at the revolution; and has ſince been gradually enlarged, and carried to an amazing extent. The various methods above mentioned have been uſed in their turns; but perpetual annuities have been granted for the greateſt part; and, even when the money was originally advanced on other conditions, the lenders have been ſometimes induced, by ſubſequent offers, to accept of perpetual annuities, inſtead of the former terms. The debt for which perpetual annuities are granted, is called the *redeemable debt*, and the other is called the *irredeemable debt*. Although the debts thus contracted by government are ſeldom paid for a long term of years; yet, any creditor of the public may obtain money for what is due to him when he pleaſes, by transferring his property in the funds to another; and regular methods are appointed for tranſacting theſe transfers, in an eaſy manner. By means of this, the ſtocks become a kind of circulating capital; and have the ſame effect, in ſome reſpects, as the circulating money in the nation. When a ſtockholder transfers his ſhare, he may ſometimes be able to obtain a greater price than the original value, and at other times be obliged to accept of a leſs one. The value of the funds depends on the proportion between the intereſt they bear, and the benefit which may be obtained by applying the money to other purpoſes. It is influenced by the plenty or ſcarcity of money, and by the quantity of the public debt; and it is impaired by any event which threatens the ſafety, or weakens the credit, of the government.

Theſe *funds*, in Britain, have been all formed into the four following claſſes or diviſions: the *Aggregate fund*, the *South Sea fund*, and the *Sinking fund*. Of all theſe, but more eſpecially the laſt, *the general fund*, we ſhall give an account in the order in which they have been now named. The *aggregate fund* was eſtabliſhed by an act of Geo. I. cap. 12. in 1715. It had this name given it, becauſe it conſiſted of a great variety of taxes and ſurpluſſes of taxes and duties which were in that year conſolidated, and given as a ſecurity for the diſcharge of the intereſt and principal of debts due to the Bank of England, and ſome other public debts; and alſo for the payment of 120,000*l*. per ann. to the civil liſt. Into this *fund* are brought the two thirds and one half ſubſidy of tonnage and poundage; half the inland duties on tea and coffee; the houſe-money granted by the 7th of Will. III. the duty on hops; the duties on low wines, brandy, and Britiſh ſpirits; all arrears of land taxes; all public monies not appropriated; the ſurpluſſes of the ninepenny exciſe, of the five ſevenths of the Bank nine penny exciſe, of the revenues in the annuity acts of the 4th, 5th, and 6th of queen Anne, &c. and, by an act of the 1ſt of Geo. III. all the duties conſtituting the revenue of the civil liſt. The whole produce or income of this *fund* had been for a few years before 1778 about 2,600,000*l*. per annum.

The *South Sea fund* was eſtabliſhed, by ſtat. 3. Geo. I. cap. 9. in 1716; and is ſo called, becauſe appropriated to pay the intereſt of the South Sea company's capital. It conſiſts of a duty on candles, and certain impoſts on wines, vinegar, tobacco, and Eaſt India goods. Its produce of late has been about half a million per ann. The *general fund* was alſo eſtabliſhed, by ſtat. of Geo. I. cap. 7. in 1716, and conſiſt of a ſubſidy on goods exported; a tax on hackney coaches and chairs; duties on ſoap, hides, ſtamps, and policies of inſurance; 700*l*. per week letter money; a moiety of the inland duties on tea and coffee; 39,855*l*. per annum out of the hereditary exciſe on beer for bankers annuities. All theſe taxes and payments have for ſome years amounted to a little more than a million per ann. and are appropriated to the diſcharge of the intereſt of 7,808,087*l*. (originally 10,000,000*l*.) capital ſtock of South Sea annuities, together with charges of management.

All that remained of the produce of the taxes thus digeſted into theſe three *funds*, after ſatisfying the charges upon them, was in the ſame year (or 1716) carried into a fourth *fund*, to which was given the name of the *ſinking fund*, becauſe appropriated to the purpoſe of ſinking the public debts. The words of the act of the 3d of Geo. I. which eſtabliſhed this *fund*; are, "All the monies to be raiſed from time to time, as well of the exceſs and ſurplus of an act made this ſeſſion for redeeming the *funds* of the Bank of England; and of the exceſs or ſurplus by virtue of one other act made likewiſe this ſeſſion for redeeming the *funds* of the South Sea company; as alſo, for the exceſs or ſurplus of the duties and revenues by this act appropriated as aforeſaid; aud the overplus monies of the ſaid *general fund* by this act eſtabliſhed; ſhall be appropriated to the diſcharging the principal and intereſt of ſuch national debts as were incurred before the 25th of December, 1716, and are declared to be national debts: and to or for no other uſe, intent, or purpoſe whatſoever." The operations and progreſs of this *ſinking fund* form ſo important a part of the hiſtory of Britain, that a more particular account of it will be here proper. Before its eſtabliſhment there had exiſted many ſmaller *funds* of the ſame nature: that is, ſuch duties or taxes had been provided for paying the intereſts of particular loans, as afforded ſurpluſſes by which the principal itſelf was to be gradually redeemed; this was the common practice in the reigns of king William and queen Anne. Moſt of the public duties were given for terms of years; and at the end of thoſe terms they ceaſed of courſe, unleſs continued for farther terms by new acts of parliament; and, in general, it was provided, when any money was raiſed, that the principal ſhould be cancelled either by time, as in the caſe of the ſale of long and ſhort annuities, or by the ſurpluſſes of the duties charged with the payment of the intereſt. This was an excellent plan; but it was by no means carried ſteadily into execution. In the year 1720, moſt of the long and ſhort annuities were converted into redeemable perpetuities, at the expence of above three millions; and the ſurpluſſes of the duties charged with particular loans were often ſo broken into, by being either charged with new loans before they had cancelled the old, or ſpent on current ſervices, as to be rendered incapable of anſwering the end intended by them. In conſequence partly of this bad management, the public debts at the acceſſion of the houſe of Hanover were ſo much increaſed as to be generally reckoned inſupportable: and their reduction was made one of the firſt objects of parliamentary attention. This gave riſe, in 1716, to the inſtitution of the *fund* of which we are giving an account, the father of which was (as has been generally ſaid) ſir Robert Walpole, but, in reality, the earl of Stanhope. All the taxes, except the land-tax, and five pence per buſhel malt-tax, were now made perpetual, and diſtributed into the three *funds* which have been deſcribed, the ſurpluſſes of which, for ever afterwards, were to be held ſacred, and to be applied inviolably, according to the words of the act juſt recited, to the redemption of the national debt. Theſe taxes have been always voted by parliament from year to year; they are, on this account, diſtinguiſhed by the name of the annual taxes, and wholly employed, as far as they will go, in bearing the current expences of every year. A conſiderate perſon might have ſuſpected, that the ſame cauſes which had rendered former partial appropriations ineffectual, would deſtroy the efficacy of this. There ſeemed, however, to be reaſon for hoping the contrary: for, Firſt, the future happineſs and glory of the kingdom, were thought to depend on this appropriation; and the law which eſtabliſhed it was declared to be a fundamental law of this realm. In conformity to this, ſecondly, the words of this law were made as ſtrong as they could well be; and in order to give additional force to it, a repetition of it, in the ſame words, was inſerted in an act of the 5th of Geo. I. cap. 3. Particular notice ſhould be taken of theſe words: they order that all the ſurpluſſes of the taxes then made perpetual, ſhall be applied to the diſcharge of the public debts, and "to no other uſe or intent whatever." When, therefore, a debt had been paid off, the addition ariſing from that payment to the ſurpluſſes (or the annuity diſengaged by it) became a part of the *fund*, and, together with it, was to be employed in diſcharging farther debts. And the ſame being true of every ſucceſſive annuity diſengaged by every payment, the *fund*, if never miſapplied, muſt neceſſarily have operated in ſinking the public debt, in the ſame manner that money accumulates, when put out to bear compound intereſt. And in this way this *fund* did in fact operate for a few years. While in its infancy, it was watched over with great care; the improvement, and the inviolable application of it were recommended in moſt of the ſpeeches from the throne, and echoed back in the addreſſes of the houſe of commons. It is particularly obſervable, that ſo well did our miniſters then underſtand the nature and importance of this *fund*, that rather than encroach upon it, they frequently borrowed money in order to defray the neceſſary expences of government. From ſome publications in 1726 it appears, that ſome perſons had been led to apprehend this zeal of the miniſtry would not be permanent, becauſe it was not their intereſt to pay off the public debt, on account of the dependence and influence created by it. In anſwering this objection, the writers on the ſide of the court called ſuch an apprehenſion an indecent jealouſy, and took upon them to aſſure the public, "that in no poſſible exigence of affairs could our miniſters ever approve of or recommend the alienation of the *ſinking fund*." Happy would it have been for Britain had this proved true; but in a little time it appeared, that the apprehenſions which had been ſtyled indecent jealouſies, were too well grounded. Men in power came ſoon to ſee, that this *fund* was advancing too faſt in its operations, and to change their zeal for it into a reſolution to deſtroy it; this will abundantly appear from the following facts.

Charging the income of the *ſinking fund* with the payment of the intereſt of new loans, is an encroachment upon it, no leſs ſubverſive of its efficacy than depriving it of groſs ſums; there being no difference between taking from it the annual intereſt of a ſum, and that ſum itſelf. Between the years 1727 and 1732 ſeveral encroachments of this kind had been made upon it; but, being of a leſs obvious nature, they paſſed without meeting with any particular oppoſition. The finiſhing blow was given it in the year 1733. In that year, in order to keep the land-tax at one ſhilling in the pound, as it had been the year before, it was neceſſary either to borrow half a million for the current ſervice, or to take this ſum from the *ſinking fund*. The laſt method was choſen, and propoſed by ſir Robert Walpole to the houſe of commons. Long and warm debates enſued. A propoſal to alienate, in a time of profound peace, a *fund* which the law had made ſacred, and the alienation of which *no poſſible exigence of public affairs* could juſtify, only for the ſake of keeping the land-tax for one year at one ſhilling in the pound, juſtly kindled the indignation of the patriotic party. They urged the prohibition of the law, the faith of parliament, and the ſecurity of the kingdom. The propoſer of the alienation was reminded of his inconſiſtency and treachery, in endeavouring to beat down that very monument of glory which he had boaſted of having erected for himſelf; and ſir John Barnard warned him, that he was drawing upon himſelf the curſes of poſterity. But all arguments were vain. The miniſtry pleaded that the landed intereſt wanted eaſe: that there was no occaſion for being in a hurry to pay the national debt; and that the circumſtances of the kingdom had altered ſo much ſince the eſtabliſhment of the *ſinking fund*, that the competition then among the public creditors was, not who ſhould be firſt, but who ſhould be laſt paid. Thus argued, among others, ſir Robert Walpole. His reaſons prevailed; and the houſe of commons, not uſed to refuſe him any thing, conſented.

The practice of alienating the *ſinking fund* having been thus begun, went on of courſe. In the next year, or 1734, 1,200,000*l.* was taken from it. In 1735, and 1736, it was anticipated and mortgaged. Thus expired, after an exiſtence of a few years, the *ſinking fund*; that ſacred bleſſing (as it was once thought) and the nation's only hope. Could it have eſcaped, it would long before this time have eaſed Britain of all its debts, and left it a ſafe and happy country. In order to obtain a juſter ſenſe of this, let us here compare what it would have done had it never been miſapplied, with what it has done. Though the act that eſtabliſhed it was paſſed, as already ſaid, in 1716, it did not begin its operations till 1719, when three quarters of a million in old exchequer bills were paid off with it. The intermediate time had been employed in laying the foundations of this *fund*, and providing an income for it, by a general reduction of the public debts, from an intereſt of ſix per cent. and other higher intereſts, to five per cent. What made this reduction then practicable was a rapid fall of the intereſt of money, which begun (in conſequence of an increaſe of trade producing an influx of money) a little before the acceſſion. The legal intereſt of money was reduced in 1714, from ſix to five per cent. and the means uſed by government for accompliſhing this reduction were, firſt, the addition (at Michaelmas 1717) of the intereſt of ſome debts bearing five per cent. to the principal in order to make uſe of the produce of the taxes which ſhould have paid the intereſt, in diſcharging the bankers debt and ſome other debts bearing ſix per cent. Secondly, loans of five per cent. obtained chiefly from the Bank, and the South Sea company, to pay off ſuch of the public creditors as did not chuſe to accept a lower intereſt than ſix per cent.

After this reduction, the three *funds*, before deſcribed, produced a ſurplus of above half a million per annum. In 1727 this ſurplus was increaſed to 939,103*l.* and in 1733 (the year when the practice of alienating it begun) it had been increaſed ſo much by the redemptions made with it, and by a ſecond reduction of intereſt in 1727 from five to four per cent. that its medium for five years had been 1,212,000*l.* per annum. Had it, from the year 1732, been allowed to increaſe beyond this (except from the intereſt of debts paid by it), and been applied for the firſt twenty five years to the payment of debts bearing four per cent. intereſt, and afterwards to the payment of debts bearing three per cent. it would in the year (1779) have completed the redemption of one hundred and forty nine millions of debt, leaving the public, during this whole period, in poſſeſſion of all the ſurpluſſes which have ariſen in the revenue beyond 1,212,000*l.* except thoſe produced by redemptions. It is not poſſible to conceive the beneficial effects with which this would have been attended, or the vigour which would have been all along given to public credit by ſuch a *fund*, and by the proſpect it would have given of a ſpeedy annihilation of almoſt all the public debts, and the diſengagement of taxes bringing in above five millions per annum, to be either aboliſhed, or (ſhould a war prove neceſſary) to be continued a few years longer for carrying it on without making any addition to the public burdens. No perſon who duly attends to this, and wiſhes well to England, can avoid execrating the policy which firſt produced, and has ſince continued, the alienation of the *ſinking fund*, and converted an expedient for ſaving the kingdom, into a ſupply for extravagance, and a ſupport of corruption and deſpotiſm. This, however, is a policy which it may be expected men in power will always uſe when they can; for few of them have ever ſhewn themſelves ſuperior to the temptations of power, or virtuous enough to avoid uſing all means to ſtrengthen and extend it.

Many ſchemes of different kinds have been formed for paying the public debts; and certain it is, that nothing can be of more importance. But the nature of things doth not admit of any method of doing this ſo expeditiouſly and effectually as an unalienable *ſinking fund*; for in ſuch a *fund* (it has been ſhewn) money is improved at compound intereſt, and therefore in the moſt perfect manner. The writers, therefore, who have employed themſelves in contriving ſuch ſchemes might have ſpared their labour. The beſt of all ſchemes has been long known and eſtabliſhed, and received all the weight and efficiency which could be given it by the moſt ſolemn acts of legiſlature. But no legiſlature can give ſecurity againſt itſelf. No parliament can do any thing which it may not undo, eſpecially if under any undue influence. We have now ſeen what the *ſinking fund* would have done, had it ſuited the views of the Britiſh miniſtry in 1733, to ſuffer it to go on with its operations. Let us next compare this with what it has done. In 1737 and 1738, a million of the ſtock of Bank annuities and two millions of the ſtock of South Sea annuities were redeemed with it. For twelve years after 1738, it was wholly applied to the current expences of every year. In 1749, the intereſt of near fifty eight millions of the public debts was reduced from four to three one half per cent. intereſt for ſeven years, and afterwards to three per cent. for ever; and by this third reduction, an addition was made to the *ſinking fund* of near 600,000*l.* per ann. But notwithſtanding this addition, no more than three millions of the public debts were redeemed by it, during the interval of peace between the years 1748 and 1756.

By an act of the 25th of Geo. II. 1752, a change was made in the *ſinking fund*, which it is neceſſary to mention. Before this act the *ſinking fund* conſiſted only of the clear ſurpluſſes of the aggregate, the general, and the South Sea company's *funds*. By the war, which began in 1740, there was an addition made to the public debt of near thirty two millions. This occaſioned a great increaſe of taxes; and the practice was, whenever any new tax produced leſs than the intereſt with which it was charged, to make good the deficiency out of the *ſinking fund*, and afterwards to replace the ſum taken from it out of the ſupplies for the following year. But whenever a tax produced more than the charge upon it, the overplus, inſtead of being carried to the *ſinking fund*, was made a part of the ſupplies for the year. By the act juſt mentioned, all the new taxes, together with all the annuities to the payment of which they had been appropriated, were ordered to be carried into the *ſinking fund*, and formed into one general account. Moſt of the new taxes having proved deficient, this *fund* at firſt loſt more than it gained by the change, but the loſs was afterwards more than made up; firſt, by the ſaving which was produced by the reduction of intereſt from three one half per cent. to three per cent. in 1757; and ſecondly, by the addition, in the ſame year, of the ſalt duties to this *fund*, after they had completed the redemption of a million with which they had been charged in 1745.

The war which began in 1756, added ſeventy one millions and a half to the public debts. This produced a new increaſe of taxes, which (in conformity to the conſolidating act juſt mentioned) have been brought to the general *ſinking fund* account, together with the annuities or intereſts with the payment of which they are charged. And it is now the conſtant practice, whenever a new *fund* or tax is created for paying the intereſt of a loan, to carry both into the *ſinking fund*; in conſequence of which this *fund* gains when the tax happens to produce more, but loſes when it produces leſs than the intereſt which it has been given to pay. The *ſinking fund*, therefore, which, before the conſolidating act, conſiſted only of the ſurpluſſes of the aggregate, general, and South-ſea company's *funds*, conſiſts now of the clear ſurplus of all the appropriated taxes. There is but one tax excepted; and that is, the additional tax upon houſes and windows, granted in 1758, towards paying the intereſt of four millions and a half then borrowed. This tax has never been made a part of the *ſinking fund*; and, having always proved deficient to the amount of about 45,000*l.* per ann. the deficiency is conſtantly made good by the *ſinking fund*, and afterwards replaced from the ſupplies.

Before the laſt reduction of the intereſt of the public debts, the *ſinking fund*, having ſuffered greatly from various encroachments upon it, produced little more than a million per ann. But after this reduction, and its increaſe by the addition of the ſalt-duties, it produced near two millions per ann. In 1764 it produced at Michaelmas, after making good deficiencies, 2,105,000*l.* nearly. For five years after 1764, its average produce, reckoned to Chriſtmas in every year, was 2,234,780*l.* For five years, ended in 1774, its average produce was 2,610,759*l.* In 1775, it produced 2,917,869*l.* In 1776, 2,166,517*l.* In 1777 it was charged with an annuity of 100,000*l.* per ann. to the civil liſt; and, after paying this annuity and half a year's intereſt of five millions borrowed in that year, it produced nearly 2,700,000*l.* In 1778 it was taken at three millions: but did not produce, after paying the ſaid annuity, and making good the intereſts of the new loans in 1777 and 1778, more than two. It appears from this detail, that ſince the peace in 1763 the income of the *ſinking fund* has increaſed conſiderably. The cauſes of this have been partly the falling in of life-annuities, and the greater productiveneſs of the taxes occaſioned by the increaſe of luxury. But the principal cauſe has been the falling in of the intereſt of about ten millions and a half of the public debts, which had been diſcharged during the twelve years of peace between 1763 and 1775. This diminution of the public debts has been made not by the *ſinking fund*, but by a contribution from the Eaſt India company of 400,000*l.* per ann. begun in 1768, and continued for five years; by the profits of ten lotteries; by the compoſition for maintaining French priſoners; ſale of French prizes taken before the declaration of war in 1756; and other extraordinary receipts, amounting in all to above eight millions. This *fund*, therefore, did not pay off more than two millions and a half, the reſt of its produce having been employed in bearing the expences of the peace eſtabliſhment, which, during this period, was nearly double to what it had been in any former period.

To the ſum juſt mentioned, add three millions paid off in the peace between 1748 and 1756, and three millions paid off in 1736 and 1737, and it will appear that the whole amount of the public debts paid off by the *ſinking fund*, ſince its firſt alienation in 1733, is only eight millions and a half; whereas it has been ſhewn, that had only 1,212,000*l.* per ann. of it been applied inviolably to the redemption of the public debts, one hundred and forty-nine millions would have been paid, and conſequently, the nation extricated and ſaved. It has been ſaid, that when money is wanted for defraying public expences, it makes no difference whether it is obtained by diverting the *ſinking fund*, or by a new loan. There cannot be a worſe fallacy than this. Money in a *ſinking fund*, if never alienated, is improved at compound intereſt; but, when procured by a loan, bears only ſimple intereſt. A nation, therefore, whenever it applies the income of ſuch a *fund* to current expences rather than the redemption of its debts, chuſes to loſe the benefit of compound intereſt in order to avoid paying ſimple intereſt; and the loſs in this caſe is equal to the difference between the increaſe of money at compound and ſimple intereſt. The following calculation will ſhew what this difference is.

One penny put out at our Saviour's birth to five per cent. compound intereſt, would, before the preſent year, have increaſed to a greater ſum than would be contained in a hundred and fifty millions of earths, all ſolid gold. But, if put out to ſimple intereſt, it would, in the ſame time, have amounted to no more than ſeven ſhillings and ſix pence. All governments that alienate *funds* deſtined for reimburſements, chuſe to improve money in the laſt rather than the firſt of theſe ways. See, on the ſubject of this article, Dr. Price's Appeal to the Public on the Subject of the National Debt. Alſo his Obſervations on Reverſionary Payments, &c. chap. iii. And additional Obſervations on Civil Liberty, part iii.

The term *ſtock* is uſed in the ſame ſenſe, as that of funds, and is alſo applied to the ſums which form the capital of the bank of England, the Eaſt India and South-Sea companies; the proprietors of which are entitled to a ſhare of the profits of the reſpective companies. The buſineſs of ſtock-jobbing is founded on the variation of the prices of ſtock. Perſons poſſeſſed of real property may buy or ſell ſtock, according to their notion that the value is likely to riſe or fall, in expectation of making profit by the difference of price. And a practice has taken place among perſons who often poſſeſs no property in the funds, to contract for the ſale of ſtock againſt a future day, at a price now agreed on. For inſtance: A agrees to ſell B 1000*l.* of bank-ſtock, to be transferred, in 20 days, for 1200*l.* A has, in fact, no ſuch ſtock; but, if the price of bank-ſtock, on the day appointed for the transfer, ſhould be only 118 *per cent.* A may purchaſe as much as will enable him to fulfil his bargain for 1180*l.* and thus gains 20*l.* by the tranſaction; on the contrary, if the price of bank-ſtock be 125 *per cent.* he will loſe £. 50. The buſineſs is generally ſettled without any actual purchaſe or transfer of ſtock, by A paying to B, or receiving from him, the difference between the current price of the ſtock on the day appointed, and the price bargained for. This practice, which is really nothing elſe than a wager concerning the price of ſtock, is contrary to law; yet it is carried on to a great extent. In the language of Exchange-alley, where matters of this kind are tranſacted, the buyer is called a *bull*, and the ſeller a *bear*. As neither party can be compelled by law to implement theſe bargains, their ſenſe of honour, and the diſgrace and loſs of future credit, which attend a breach of contract, are the principles by which the buſineſs is ſupported. When a perſon declines to pay his loſs, he is called a *lame duck*, and dare never afterwards appear in the Alley. This opprobrious treatment, however, is not beſtowed on thoſe whoſe failure is owing to want of ability, providing they make the ſame ſurrender of their property voluntarily, which the law would have exacted if the debt had been entitled to its ſanction.

The capital advanced to the public, in the form of transferable ſtocks, and bearing intereſt from taxes appropriated for that purpoſe, is called the *funded debt*. Beſides, there is generally a conſiderable ſum due by government, which is not diſpoſed of in that manner, and therefore is diſtinguiſhed by the appellation of the *unfunded debt*. This may ariſe from any ſort of national expence, for which no proviſion has been made, or for which the proviſion has proved inſufficient. The forms of the unfunded debts are various, according to the circumſtances by which they are occaſioned. But there are two regular branches of this debt, which always ſubſiſt, to a greater or leſſer extent.

1ſt, *Exchequer Bills*. Theſe are iſſued from the exchequer, generally by appointment of parliament, and ſometimes without ſuch appointment, when exigencies require. They bear intereſt from the time when iſſued, and are taken in by the bank of England, which promotes their circulation.

2d, *Navy Bills*. The ſums annually granted for the navy have always fallen ſhort of what that ſervice required. To ſupply that deficiency, the admiralty iſſues bills in payment of victuals, ſtores, and the like, which bear intereſt ſix months after the time iſſued. The debt of the navy thus contracted is diſcharged, from time to time, by parliament. In time of war, the public expences, ſince the revolution, have always been much greater than the annual revenue; and large ſums have conſequently been borrowed. In time of peace, the revenue exceeds the expence, and part of the public debts have frequently been paid off. But, though there have been more years of peace than of war ſince the funds were eſtabliſhed, the debts contracted during each war have much exceeded the payments during the ſubſequent peace.

FUNDAMENT, the anus or aperture, through which an animal voids his excrements.

FUNDAMENTAL, in general, ſomething that ſerves as a baſe or foundation for another.

FUNDAMENTAL, in muſic. A *fundamental ſound* is that which forms the loweſt note of the *chord*, and from whence are deduced the harmonical relations of the reſt; or, which ſerves for a key to the tone. The *fundamental baſs* is that which ſerves for a foundation to the harmony. A *fundamental chord* is that whoſe baſs is fundamental, and in which the ſounds are ranged in the ſame order as when they are generated, according to the experiment ſo often repeated by M. d'Alembert in his Preliminary Diſcourſe and Elements of Muſic. But as this order removes the parts to an extreme diſtance one from the other, they muſt be approximated by combinations or inverſions; but if the baſs remains the ſame, the chord does not for this reaſon ceaſe to bear the name of *fundamental*. Such an example is this chord, *ut mi ſol*, included in the interval of a fifth: whereas, in the order of its generation, *ut ſol mi*, it includes a tenth, and even a ſeventeenth; ſince the fundamental *ut* is not the fifth of *ſol*, but the octave of that fifth.

FUNERAL *Rites*, ceremonies accompanying the interment or burial of any perſon. Theſe rites differed among the ancients according to the different genius and religion of each country. The

Egyptians, among the reſt of their funeral rites, embalmed their dead. Among the ancient Greeks it was uſual ſometimes, before the interment, to put a piece of money into the mouth of the deceaſed, which was thought to be Charon's fare for wafting the departed ſoul over the infernal river. This ceremony was not uſed in thoſe countries which were ſuppoſed to be ſituated in the neighbourhood of the infernal regions, and to lead thither by a ready and direct road. The corpſe was likewiſe furniſhed with a cake, compoſed of flour, honey, &c. which was deſigned to appeaſe the fury of Cerberus the door-keeper of hell, and to procure the ghoſt a ſafe and quiet entrance.

During the time the corpſe continued in the houſe, there ſtood before the door a veſſel of water: the deſign of which was, that thoſe concerned about the body might purify themſelves by waſhing; it being the opinion of the Greeks, as well as of the Jews, that pollution was contracted by touching a dead body. The ceremonies by which they expreſſed their ſorrow for the death of their friends, were various; but it ſeems to have been a conſtant rule to recede as much as poſſible in habit and behaviour from their ordinary cuſtoms. For this reaſon they abſtained from banquets and entertainments; they diveſted themſelves of all ornaments; they tore, cut off, or ſhaved their hair, which they caſt into the funeral pile, to be conſumed with the body of their deceaſed friend. Sometimes they threw themſelves on the ground, and rolled in the duſt, or covered their head with aſhes; they beat their breaſts, and even tore their fleſh with their nails, upon the loſs of a perſon they much lamented. When perſons of rank, ſuch as public magiſtrates or great generals, died, the whole city put on a face of mourning; all public meetings were intermitted; the ſchools, baths, ſhops, temples, and all places of concourſe, were ſhut up. Interring or laying the dead on the ground, ſeems to have been the moſt ancient practice among the Greeks; though burning came afterwards to be generally uſed among them. It was cuſtomary to throw into the funeral pile, thoſe garments the deceaſed uſually wore. The pile was lighted by one of the deceaſed's neareſt relations or friends, who made prayers and vows to the winds to aſſiſt the flames, that the body might quickly be reduced to aſhes; and during the time the pile was burning, the dead perſon's friends ſtood by it, pouring libations of wine, and calling upon the deceaſed. When Numa reformed the religion of Rome, he ordered that the pontiffs ſhould have the care of the funeral ceremonies; which, in moſt reſpects, were like thoſe of the Greeks already deſcribed.

The funeral rites among the Hebrews were ſolemn and magnificent. When any perſon was dead, his relations and friends rent their cloths; which cuſtom is but faintly imitated by the modern Jews, who only cut off a bit of their garment, in token of affliction. It was uſual to bend the dead perſon's thumb into the hand, and faſten it in that poſture with a ſtring; becauſe the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying place, they made a ſpeech to the dead in the following terms: "Bleſſed be God, who has formed thee, fed thee, maintained thee, and taken away thy life. O dead! he knows your numbers, and ſhall one day reſtore your life, &c." Then they ſpoke the elogium, or funeral oration, of the deceaſed; after which they ſaid a prayer, called the *righteouſneſs of judgment*; then turning the face of the deceaſed towards heaven, they called out, "Go in peace."

The ancient Chriſtians teſtified their abhorrence of the Pagan cuſtom of burning the dead; and always depoſited the body entire in the ground: and it was uſual to beſtow the honour of embalming upon the martyrs at leaſt, if not upon others. They prepared the body for burial, by waſhing it with water, and dreſſing it in a funeral attire. The exportation or carrying forth of the body was performed by near relations, or perſons of ſuch dignity as the circumſtances of the deceaſed required. Pſalmody, or ſinging of pſalms, was the great ceremony uſed in all funeral proceſſions among the ancient Chriſtians. In the Romiſh church, when a perſon is dead, they waſh the body, and put a crucifix in its hand. At its feet ſtands a veſſel full of holy water, and a ſprinkler, that they who come in may ſprinkle both themſelves and the deceaſed. In the mean time ſome prieſt ſtands by the corpſe, and prays for the deceaſed till it is laid in the earth. In the funeral proceſſion, the exorciſt walks firſt, carrying the holy water; next the croſs bearer, afterwards the reſt of the clergy, and laſt of all the officiating prieſt. They all ſing the *miſerere*, and ſome other pſalms; and at the end of each pſalm a *requiem*. We learn from Alet's ritual, that the faces of deceaſed laymen muſt be turned away towards the altar, when they are placed in the church; and thoſe of the clergy towards the people. The corpſe is placed in the church ſurrounded with lighted tapers: after the office for the dead, maſs is ſaid; then the officiating prieſt ſprinkles the corpſe thrice with holy water, and as often throws incenſe on it. The body being laid in the grave, the friends and relations of the deceaſed ſprinkle the grave with holy water.

The funeral ceremonies of the Greek church, are much the ſame with thoſe of the Latin. It need only to be obſerved, that, after the funeral ſervice, they kiſs the crucifix, and ſalute the mouth and forehead of the deceaſed: after which each of the company eats a bit of bread and drinks a glaſs of wine in the church, wiſhing the ſoul a good repoſe, and the afflicted family all conſolation.

FUNERAL *Games*, a part of the ceremony of the ancient funerals. It was cuſtomary for perſons of quality, among the ancient Greeks and Romans, to inſtitute games, with all ſorts of exerciſes, to render the death of their friends more remarkable. This practice was generally received, and is frequently mentioned by ancient writers. Patroclus's funeral games take up the greateſt part of one of Homer's Iliads; and Agamemnon's ghoſt is introduced by the ſame poet telling the ghoſt of Achilles, that he had been a ſpectator at a great number of ſuch ſolemnities. The celebration of theſe games among the Greeks, moſtly conſiſted of horſe-races; the prizes were of different ſorts and value, according to the quality and magnificence of the perſon that celebrated them. The garlands, given to victors on this occaſion, were uſually of parſly, which was thought to have ſome particular relation to the dead.

Thoſe games, among the Romans, conſiſted chiefly of proceſſions; and ſometimes of mortal combats of gladiators around the pile. They, as well as the Greeks, had alſo a cuſtom, though very ancient, of cutting the throats of a number of captives before the pile, as victims to appeaſe the manes of the deceaſed. Cæſar relates, that the Gauls had this cuſtom. The funeral games were aboliſhed by the emperor Claudius.

FUNGI, from σφογγος, *fungus*, one of the ſeven families or tribes of the vegetable kingdom, according to Linnæus, comprehending all thoſe who are of the muſhroom kind. See Syſtem of BOTANY, Claſs XXIV. Order IV. Plate VI.

FUNGUS, in ſurgery, a fleſhy *tumor*, or excreſcence, very ſpongeous, ſoft, and pale; ariſing on the membranes, tendons, and other nervous parts, in conſequence of ulcers, wounds, contuſions, and ſtrains. See Syſtem of SURGERY.

FURIES, in Pagan antiquity, certain goddeſſes whoſe office it was to puniſh the guilty after death. They were three in number; *Alecto*, *Megæra*, and *Tiſiphone*; who were deſcribed with ſnakes inſtead of hair, and eyes like lightning, carrying iron chains and whips in one hand, and in the other flaming torches; the latter to diſcover, and the former to puniſh, the guilty: and they were ſuppoſed to be conſtantly hovering over ſuch perſons as had been guilty of any enormous crime.

FURLONG, an Engliſh long meaſure, containing the eighth part of a mile. The Engliſh *furlong* is equal to forty poles or perches, and the perch to 16½ feet. In Scotland the *furlong* is equal to forty *falls*.

FURNACE, an utenſil, or veſſel, proper to contain fire, or to raiſe and maintain a vehement fire in, whether of coal or wood. There are divers kinds of furnaces, of various forms, and for various uſes. For a deſcription of different Furnaces for Practical Chymiſtry, and particularly *Dr. Black's* new invented one, ſee Syſtem of CHYMISTRY, under the Article *Chymical Apparatus*. For a repreſentation of them, ſee the Plate.

FUROR *Uterinus*, a ſpecies of madneſs, peculiar to women, exciting them to a vehement deſire of venery, and rendering them inſatiate therewith, and manifeſting itſelf by obſcene ſpeech and wanton behaviour. As the diſorder increaſes, the patient ſcolds, laughs, and cries by turns. The immediate cauſes of this diſeaſe are an inflammation, tenſeneſs, and irritability of the uterus and pudenda of women, and particularly of the clitoris and vagina, in which the venereal ſtimulus reſides, or the too great abundance or acrimony of the humours of theſe parts. See Syſtem of MEDICINE.

FURR, or **FUR**, in commerce, the ſkins of divers kinds of wild beaſts, dreſſed with the hair on; to be uſed as a lining, or doubling, of garments, robes, &c. either for warmth, ornament, or diſtinction of rank and dignity. The robes of kings, dukes, and peers, are lined with divers kinds of *furrs*, and, in particular, ermine, to render them more magnificent. The ſame may be obſerved of ſeveral chief magiſtrates, judges, and doctors of different faculties, in the univerſities.

FURR, in heraldry, a repreſentation of the ſkins of certain wild beaſts, ſeen, both in the doublings of the mantles of coat-armour, and in the armour itſelf. The heralds uſe two metals, five colours, and two *furrs*, or hairy ſkins: viz. ermine and vair.

FUSEE, **FUZE**, or **FUSE**, in war, an appendage of a bomb or granado-ſhell, by which the powder, or compoſition, in the ſhell, is ſet on fire, to do the deſigned execution. The word is French, and literally denotes a *ſpindle*. *Fuzee*, or *Fuſee*, is alſo ſometimes uſed to denote a *fire-lock*.

FUSIBILITY, that quality in metals, and minerals, which diſpoſes them for *fuſion*. Gold is more *fuſible* than iron, or copper; but leſs ſo than ſilver, tin, and lead. Borax is frequently mixed with metals, to render them more *fuſible*.

FUSION, the ſolution, or melting, of metals, minerals, &c. by means of fire; or the act of changing them from their ſolid ſtate to a fluor. See Syſtem of CHYMISTRY, Part II.

FUTURE, ſomething to come hereafter. We ſay a *future* ſtate, a *future* contingency; there is none but God to whom *future* things are preſent.

FUTURE, or **FUTURE** *Tenſe*, in grammar, denotes an inflexion of verbs, whereby they denote, that a thing will be in ſome time yet to come. As, the laſt day will come: I ſhall ſee an end.

G

G, The ſeventh letter in our alphabet, and the fifth conſonant: though in the alphabets of all the oriental languages, the Hebrew, Phœnician, Chaldee, Syriac, Samaritan, Arabic, and even Greek, *G* is the third letter. The Hebrews call it *ghimel*, or *gimel*, q. d. *camel*; becauſe it reſembles in its form the neck of that animal; and the ſame appellation it bears in the Samaritan, Phœnician, and Chaldee; in the Syriac it is called *gomel*, in Arabic *giim*, and in Greek *gamma*. The letter *G* is of the mute kind, and cannot be any way ſounded without the help of a vowel. It is formed by the reflection of the air againſt the palate, made by the tongue, as the air paſſes out of the throat; which Martianus Capella expreſſes thus, *G ſpiritus cum palato*, ſo that the *G* is a palatal letter. *G* in Engliſh has two ſounds, one from the Greek Γ, and the Latin, which is called that of the hard *G*, becauſe it is formed by a preſſure ſomewhat hard of the fore-part of the tongue againſt the upper gum; which ſound it retains before *a, o, u, l, r*; as *gate, go, gull*. At the end of a word it is always hard, as *ring, ſing*, &c. The other ſound, called that of the ſoft *G*, reſembles that of *j*, and is commonly, though not always, found before *e* and *i*, as in *gem* and *gibbet*. To this rule, however, there are many exceptions; *G* is often hard before *i*, as *give*, &c. and ſometimes before *e*, as *get*, &c. It is alſo hard in derivatives from words ending in *g*, as *ſinging, ſtronger*, &c. and generally before *er*, at the end of words, as *finger*. *G* is mute before *n*, as *gnaſh, ſign*. *Gh* has the ſound of the hard *G* in the beginning of a word, as *ghoſtly*; in the middle, and ſometimes at the end, it is quite ſilent, as *right, though*. At the end of a word *Gh* has often the ſound of *f*, as *laugh*. Johnſon.

The form of our *G* is taken from that of the Latins, who borrowed it from the Greeks; the Latin *G* being certainly a corruption of the Greek gamma, Γ, as might eaſily be ſhewn, had our printers all the characters and forms of this letter, which we meet with in the Greek and Latin MSS. through which the latter paſſed from Γ to *G*. As to the gamma of the Greeks, it is manifeſtly the ג of the Hebrews or Samaritans. All the difference between the gamma and ghimel conſiſts in this, that the one is turned to the right, and the other to the left, according to the different manners of writing and reading, which obtained among thoſe different nations; ſo that all the pains Salmaſius has taken on Solinus, to prove that the *G* was derived from the Greek kappa, are loſt. G is alſo uſed, in muſic, to ſignify one of the clefs; viz. that of the higheſt part, called the *treble* or *alt*.

GABEL, or Gabelle in the French cuſtoms, a duty or impoſition on ſalt. The *gabel* is let out to farm; and makes the ſecond article in the king's revenue. There are three farms of *gabels*. The produce of this impoſt is ſo conſiderable, that it is computed to make one fourth of the whole revenue of the kingdom.

GABIONS, in fortification, &c. are large cylindric baſkets, open at both ends, made of ozier twigs, about three feet high, and as much in diameter: having nine or ten ſtakes about an inch and a half in diameter, which exceeds the baſket-work about five or ſix inches, and are pointed. Theſe ſerve in ſieges to carry on the approaches under cover, when they come pretty near the fortification.

GABLE, or Gable *End* of a houſe, is the upright triangular end; from the cornice, or eaves, to the top of its roof.

GABRES, or Gavres, a religious ſect in Perſia and India; called alſo *Gebres, Gevres*, &c. See Magi. The Turks call the Chriſtians *Gabres*, q. d. infidels, or people of a falſe religion; or, rather, as Leunclavius obſerves, Heathens, or Gentiles: the word *Gabre*, among the Turks, having the ſame ſignification as Pagan, or Infidel, among the Chriſtians; and denoting any thing not Mahometan.

GAD *Fly*, in entomology, called œſtrus bovinus or ox-fly, a creature very troubleſome to cows, horſes, &c. This creature, examined by the microſcope, has ſeveral peculiarities worthy obſervation. It has, like the gnat, a long proboſcis, with a ſharp dart, and two darts ſheathed within it; the uſe of which is to penetrate the fleſh of animals, and feed on their blood; whereas the proboſcis ſerves to ſuck the juices, &c. from fruits, flowers, and leaves of plants. The eggs of this fly are laid in the water, and there produce a remarkable maggot, of a brown colour and long flatted figure, with a pencil of fine downy hairs at its tail, which it ſpreads into a circular form at the ſurface of the water, whilſt its head is plunged under it in ſearch of food. In deſcending, theſe hairs are drawn together in an oval form, and made to encloſe a bubble of air, by means of which the maggot is able to riſe again; and if this bubble happens to eſcape, the creature ſqueezes another out of his body to ſupply its place. The ſnout of this maggot has three diviſions, whence are thruſt out three little pointed bodies, like ſerpents tongues. Thoſe maggots are very common on the ſurface of ditch water, and the motion of their inteſtines is very ſingular and obſervable. Baker's Microſ. p. 207.

GADUS, in ichthyology, a genus belonging to the order called *Jugulares*. There are 18 ſpecies of which the following are the moſt remarkable. The *morhua*, or *common cod*, is found only in the northern parts of the world; it is, as Rondeletius calls it, an ocean fiſh, and never met with in the Mediterranean ſea. It affects cold climates, and ſeems confined between the latitudes 66° and 50°: what are caught north and ſouth of thoſe degrees being either few in quantity or bad in quality. The Greenland fiſh are ſmall, and emaciated through want of food; being very voracious, and having in thoſe ſeas a ſcarcity of proviſion. This locality of ſituation is common to many other ſpecies of this genus, moſt of them being inhabitants of the cold ſeas, or ſuch as lie within regions that can juſt claim the title of *temperate*. There are certain ſpecies found near the Canary iſlands, called *cherney*, of which we know no more than the name; but which, according to Captain Glaſs, are better taſted than the Newfoundland kind. Many of theſe ſwarm on the coaſts of Norway in the Baltic, off the Orkney and the Weſtern iſles: after which their numbers decreaſe, in proportion as they advance towards the ſouth, when they ſeem quite to ceaſe before they reach the mouth of the Straits of Gibraltar.

In our ſeas they begin to ſpawn in January, and depoſite their eggs in rough ground, among rocks. Some continue in roe till the beginning of April. The cod-fiſh in general recover quicker after ſpawning than any other fiſh, therefore it is common to take ſome good ones all the ſummer. When they are out of ſeaſon, they are thin-tailed and louſy; and the lice chiefly fix themſelves on the inſide of their mouths. The fiſh of the middling ſize are moſt eſteemed for the table; and they are choſen by their plumpneſs and roundneſs, eſpecially near the tail, by the depth of the ſulcus or pit behind the head, and by the regular undulated appearance of the ſides, as if they were ribbed. The glutinous parts about the head loſe their delicate flavour after it has been 24 hours out of the water, even in winter, in which theſe and other fiſh of this genus are in higheſt ſeaſon.

The *Egleſinus*, or *Haddock*. Large haddocks begin to be in roe in the middle of November, and continue ſo till the end of January; from that time till May they are very thin tailed, and much out of ſeaſon. In May they begin to recover; and ſome of the middling-ſized fiſh are then very good and continue improving till the time of their greateſt perfection. The ſmall ones are extremely good from May till February, and ſome even in February, March, and April, viz. thoſe which are not old enough to breed. The fiſhermen aſſert, that in rough weather haddocks ſink down into the ſand and ooze in the bottom of the ſea, and ſhelter themſelves there till the ſtorm is over; becauſe in ſtormy weather they take none, and thoſe that are taken immediately after a ſtorm are covered with mud on their backs. In ſummer they live on young herrings and other ſmall fiſh; in winter, on the ſtone-coated worms which the fiſhermen call *haddock-meat*. The grand ſhoal of haddocks comes periodically on the Yorkſhire coaſts. It is remarkable that they appeared in 1766 on the 10th of December, and exactly on the ſame day in 1767: theſe ſhoals extended from the ſhore near three miles in breadth, and in length from Flamborough-head to Tinmouth-caſtle, and perhaps much farther northwards. An idea may be given of their numbers by the following fact: Three fiſhermen, within the diſtance of one mile from Scarborough harbour, frequently loaded their coble or boat with them twice a-day, taking each time about a ton of fiſh: when they put down their lines beyond the diſtance of three miles from the ſhore, they caught nothing but dog fiſh, which ſhows how exactly theſe fiſh keep their limits. The beſt haddocks were ſold from eightpence to a ſhilling per ſcore; and the poor had the ſmaller ſort at a penny and ſometimes a halfpenny per ſcore. The large haddocks quit the coaſt as ſoon as they go out of ſeaſon, and leave behind great plenty of ſmall ones. It is ſaid that the large ones viſit the coaſts of Hamburgh and Jutland in the ſummer. It is no leſs remarkable than providential, that all kinds of fiſh (except mackerel) which frequent the Yorkſhire coaſt, approach the ſhore, and as it were offer themſelves to us, generally remaining there as long as they are in high ſeaſon, and retire from us when they become unfit for uſe. It is the commoneſt ſpecies in the London markets. They do not grow to a great bulk, one of fourteen pounds, being of an uncommon ſize, but thoſe are extremely coarſe; the beſt for the table weighing from two to three pounds. The body of the haddock is long: the head ſlopes down to the noſe: the ſpace between the hind part of the firſt dorſal fin is rigid: on the chin is a ſhort beard. On the back are three fins reſembling thoſe of the common cod fiſh: on each ſide beyond the gills is a large black ſpot. Superſtition aſſigns this mark to the impreſſion St. Peter left with his finger and thumb when he took the tribute out of the mouth of a fiſh of this ſpecies, which has been continued to the whole race of haddocks ever ſince.

The *carbonarius* or *coal fiſh*, takes its name from the black colour that it ſometimes aſſumes. Belon calls it the colfiſch, imagining that it was ſo named by the Engliſh, from its producing the ichthyocolla; but Geſner gives the true etymology. Theſe fiſh are common on moſt of our rocky and deep coaſts, but particularly thoſe of the north of Great Britain. They ſwarm about the Orkneys, where the fry are the great ſupport of the poor. The young begin to appear on the Yorkſhire coaſt the beginning of July in vaſt ſhoals, and are at that time about an inch and an half long. In Auguſt they are from three to five inches in length, and are taken in great numbers with the angling rod: they are then eſteemed a very delicate fiſh; but grow ſo coarſe when they are a year old, that few people will eat them. Fiſh of that age are from eight to fifteen inches long, and begin to have a little blackneſs near the gills and on the back, and the blackneſs increaſes as they grow older. The fry is known by different names in different places: they are called at Scarborough *parrs*, and when a year old, *billets*. About nine or ten years ago ſuch a glut of parrs viſited that part, that for ſeveral weeks it was impoſſible to dip a pail into the ſea without taking ſome. Though this fiſh is ſo little eſteemed when freſh, yet it is ſalted and dried for ſale. It is of a more elegant form than the cod fiſh: they generally grow to the length of two feet and an half, and weigh about 28 or 30 pounds at moſt.

The *merlucius*, or *hake*, is found in vaſt abundance on many of our coaſts, and of thoſe of Ireland. There was formerly a vaſt ſtationary fiſhery of hake on the Nymph Bank off the coaſt of Waterford. Mr. Smith, who wrote the hiſtory of the county of Waterford, complains even in his time (1746) of its decline. Many of the gregarious fiſh are ſubject to change their ſituations, and deſert their haunts for numbers of years, and then return again. Mr. Smith inſtances the loſs of the haddock on the Waterford ſhores, where they uſed to ſwarm; and we can bring the capriciouſneſs of the herrings, which ſo frequently quit their ſtations, as another example. Sometimes the irregular migration of fiſh is owing to their being followed and haraſſed by an unuſual number of fiſh of prey, ſuch as the ſhark kind; ſometimes to deficiency of the ſmaller fiſh, which ſerved them as food; and laſtly, in many places to the cuſtom of trawling, which not only demoliſhes a quantity of their ſpawn, that is depoſited in the ſand, but alſo deſtroys or drives into deeper waters numberleſs worms and inſects, the repaſt of many fiſh. The hake is in England eſteemed a very coarſe fiſh, and is ſeldom admitted to table either freſh or ſalted. When cured, it is known by the name of *Poor John*. Theſe fiſh are from a foot and an half to near twice that length: they are of a ſlender make, of a pale aſh colour on their backs, and of a dirty white on their bellies.

The *molva* or *ling*, takes its Engliſh name from its length, being corrupted from the word *long*. It abounds about the Scilly Iſles, on the coaſts of Scarborough, and thoſe of Scotland and Ireland, and forms a conſiderable article of commerce. This branch of trade was conſiderable ſo long ago as the reign of Edward III. an act for regulating the price of lob, *ling*, and cod, being made in his 31ſt year. In the Yorkſhire ſeas they are in perfection from the beginning of February to the beginning of May, and ſome till the end of that month. In June they ſpawn, depoſiting their eggs in the ſoft ouzy ground of the mouth of the Tees: at that time the males ſeparate from the females, and reſort to ſome rocky ground near the Flamborough-head, where the fiſhermen take great numbers without ever finding any of the female or roed-fiſh among them. While a ling is in ſeaſon its liver is very white, and abounds with a fine-flavoured oil; but as ſoon as the fiſh goes out of ſeaſon, the liver becomes red as that of a bullock, and affords no oil. The ſame happens to the cod and other fiſh in a certain degree, but not ſo remarkably as in the ling. When the fiſh is in perfection, a very large quantity of oil may be melted out of the liver by a ſlow fire; but if a violent ſudden heat be uſed for that purpoſe, they yield very little. The oil which nature hoards up in the cellular membranes of the fiſhes, returns into their blood, and ſupports them in the engendering ſeaſon, when they purſue the buſineſs of generation with ſo much eagerneſs as to neglect their food. The uſual ſize of a ling is from three to four feet; but they have been heard of ſeven feet long. The body is very ſlender; the head flat; the upper jaw the longeſt; the teeth in that jaw ſmall and very numerous; in the lower, few, ſlender, and ſharp.

The *muſtela*, or *five-bearded cod*, very much reſembles the former. The beards on the upper jaw are four, viz. two at the very end of the noſes and two a little above them; on the end of the lower jaw is a ſingle one. The fiſh are of a deep olive brown, their belly whitiſh. They grow to the ſame ſize as the former. The Corniſh fiſhermen are ſaid to whiſtle, and make uſe of the words *bod*, *bod*, *vean*, when they are deſirous of taking this fiſh, as if by that they falicitated the capture. In the ſame manner the Sicilian fiſhermen repeat their *mamaſſu di pajanu*, &c. when they are in purſuit of the ſword-fiſh.

The *torſk*, or, as it is called in the Shetlands, *tuſk* or *briſmak*, is a northern fiſh; and yet is undiſcovered lower than about the Orkneys, and even there it is rather ſcarce. In the ſeas about Shetland, it ſwarms, and forms (barrelled or dried) a conſiderable article of commerce. For the claſſification of this Genus called *Gadus*, ſee the Syſtem. For a further account of the *cod*, ſee the Articles COD and FISHERY.

GAGE, in the ſea language. When one ſhip is to windward of another, ſhe is ſaid to have the weather gage of her.

Sliding GAGE, is a tool uſed by mathematical inſtrument makers, for meaſuring and ſetting off diſtances: it conſiſts of a beam, tooth, ſliding ſocket, and the ſhoulder of the ſocket.

GALANTHUS, the *Snow Drop*; a genus of the monogynia order, belonging to the hexandria claſs of plants. There is but one ſpecies, viz. the nivalis; which is a bulbous rooted flowery perennial, riſing but a few inches in height, and adorned at top with ſmall tripetalous flowers of a white colour. There are three varieties, viz. the common ſingle flowered ſnow drop, the ſemi-double ſnow drop, and the double ſnow drop. They are beautiful little plants; and are much valued on account of their early appearance, often adorning the gardens in January or February, when ſcarce any other flower is to be ſeen. They frequently burſt forth when the ground is covered with ſnow, and continue very often till the beginning of March, making a very ornamental appearance, eſpecially when diſpoſed in cluſters towards the fronts of the borders, &c. The ſingle kind comes firſt into bloom, then the ſemi-double, and after that the double. They will ſucceed any where, and multiply exceedingly by off-ſets from the roots.

GALAXY, in aſtronomy, that long, white, luminous track, which ſeems to encompaſs the heavens like a ſwath, ſcarf, or girdle; and which is eaſily perceivable in a clear night, eſpecially when the moon does not appear. The Greeks call it γαλαξιας, *galaxy*; of γαλα, γαλακτος *milk*; on account of its colour, and appearance. The Latins, for the ſame reaſon, call it *via lactea*; and we, the *milky-way*. It paſſes between Sagittary and Gemini, and divides the ſphere into two parts. It is unequally broad; and in ſome parts is ſingle, in others double. The ancient poets, and even philoſophers, ſpeak of the *galaxy* as the road, or way, by which the heroes went to heaven. Ariſtotle makes it a kind of meteor, formed of a croud of vapours, drawn into that part by certain large ſtars diſpoſed in the regions of the heavens anſwering hereto. Others, finding that the *galaxy* was ſeen all over the globe, that it always correſponded to the ſame fixed ſtars, and that it tranſcended the height of the higheſt planets, ſet aſide Ariſtotle's opinion, and placed the *galaxy* in the firmament or region of the fixed ſtars; and concluded it to be nothing but an aſſemblage or an infinite number of minute ſtars. Since the invention of the teleſcope, this opinion has been abundantly confirmed. By directing a good teleſcope to any part of the milky way, where, before, we only ſaw a confuſed whiteneſs; we now deſcry an innumerable multitude of little ſtars. Theſe ſtars are ſo remote, that a naked eye confounds them: the like we obſerve in other ſpots, called *nebuloſe ſtars*; which, when examined with the teleſcope, are diſtinctly perceived to be cluſters of little ſtars, too faint to affect the eye ſingly.

GALBANUM, in pharmacy, a gum iſſuing from the ſtem of an umbelliferous plant growing in Perſia and many parts of Africa. In medical virtue, and ſenſible qualities, it reſembles the gum ammoniacum; but is leſs efficacious than it is in aſthmas, though more efficacious in hyſteric diſorders. When aſſa fetida is too ſtrong, galbanum may be tried; and, if it diſagrees, give ammoniacum.

GALE, a ſea phraſe, for the blowing of the wind. When the ſea is not blown ſo hard, but that a ſhip can carry her top-ſails a-trip, that is, hoiſted up to the higheſt, they ſay it is a *loom gale*. When it blows very ſtrong they ſay it is a *ſtiff gale*, or, at leaſt a *freſh gale*; but when it blows ſo hard and violently, that a ſhip cannot bear any ſail, they ſay it blows a *ſtorm*. When two ſhips are near one another at ſea, and there being but little wind blowing, one feels more of it than another, they ſay the ſhip *gales* away from the other.

GALENIC, or GALENICAL, in pharmacy; a manner of treating diſeaſes, founded on the principles of Galen. The diſtinction of *galenical* and *chymical*, was occaſioned by a diviſion of the practitioners of medicine into two ſects, which happened on the introduction of chymiſtry into medicine. Then the chymiſts, arrogating to themſelves every kind of merit and ability, ſtirred up an oppoſition to their pretenſions, founded on the invariable adherence of the other party to the ancient practice. And though this diviſion into the two ſects of galeniſts and chymiſts has long ceaſed, yet the diſtinction of medicines, which reſulted from it, is ſtill retained. Galenical medicines are thoſe which are formed by the eaſier preparations of herbs, roots, &c. by infuſion, decoction, &c. and by combining and multiplying ingredients; while thoſe of chymiſtry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, digeſtion, fermentation, &c.

GALILEANS, GALILÆI, a ſect among the ancient Jews, denominated from Judas of *Galilee*, their chief; who, eſteeming it unworthy that the Jews ſhould pay tribute to ſtrangers, raiſed up his countrymen againſt the edict of Auguſtus, which had ordered a cenſus, or enumeration, to be made of all his ſubjects. Their pretence was, that God alone ſhould be owned as maſter, and called by the name of the *Lord*; in other reſpects they had much the ſame doctrine as the Phariſees; but as they judged it unlawful to pray for infidel princes, they ſeparated themſelves from the reſt of the Jews, and performed their ſacrifices apart. As our Saviour, and his apoſtles, were of *Galilee*, they were ſuſpected to be of the ſect of *Galileans*; and it was on this principle, as St. Jerome obſerves, that the Phariſees laid a ſnare for him; aſking, whether it was lawful to give tribute to Cæſar; that in caſe he denied it, they might have an occaſion for accuſing him. Maynard's Joſeph. Ant. Jud. lib. xviii.

GALL, in the animal œconomy. See BILE.

A great number of experiments have been made upon the gall of different animals, but few concluſions can be drawn from them with any certainty. Dr. Percival, however, hath ſhewn, that putrid bile may be perfectly corrected and ſweetened by an admixture of the vegetable acids, vinegar and juice of lemons. Theſe, he obſerves, have this effect much more completely than the mineral ones; and hence, he thinks ariſes the great uſefulneſs of the vegetable acids in autumnal diſeaſes; which are always attended with a putreſcent diſpoſition of the bile, owing to the heat of the preceding ſummer. On this occaſion he takes notice of a common miſtake among phyſicians, who frequently preſcribe elixir of vitriol in thoſe diſeaſes, where vinegar or lemon juice would be much more effectual. From this effect of acids on the gall, he alſo thinks, we may ſee why the immoderate uſe of acids is ſo pernicious to digeſtion. It is neceſſary to health that the gall ſhould be in ſome degree acrid and alkaleſcent; but as acids have the property of rendering it perfectly mild and ſweet, they muſt be proportionably pernicious to the due concoction and aſſimilation of the food; which without an acrid bile cannot be accompliſhed. Hence the body is deprived of its proper nouriſhment and ſupport, the blood becomes vapid and watery, and a fatal cachexy unavoidably enſues. This hath been the caſe with many unfortunate perſons, who, in order to reduce their exceſſive corpulency, have indulged themſelves in the too free uſe of vinegar. From the mild ſtate of the gall in young children, Dr. Percival alſo thinks it is, that they are ſo much troubled with acidities.

Gall, in natural hiſtory, denotes any protuberance or tumour produced by the puncture of inſects on plants and trees of different kinds. The general hiſtory of the gall is this. An inſect of the fly kind is inſtructed by nature to take care for the ſafety of her young, by lodging her eggs in a woody ſubſtance, where they will be defended from all injuries; ſhe for this purpoſe wounds the leaves or tender branches of a tree; and the lacerated veſſels, diſcharging their contents, ſoon form tumours about the holes thus made. The external coat of this excreſcence is dried by the air: and grows into a figure which bears ſome reſemblance to the bow of an arch, or the roundneſs of a kernel. The little ball receives its nutriment, growth, and vegetation, as the other parts of the tree, by ſlow degrees, and is what we call the *gall-nut*. The worm that is hatched under this ſpacious vault, finds in the ſubſtance of the ball, which is as yet very tender, a ſubſiſtence ſuitable to its nature; gnaws and digeſts it till the time comes for its tranſformation to a nymph, and from that ſtate of exiſtence changes into a fly. After this, the inſect, perceiving itſelf duly provided with all things requiſite, diſengages itſelf ſoon from its confinement, and takes its flight into the open air. The caſe, however, is not ſimilar with reſpect to the gall-nut that grows in autumn. The cold weather frequently comes on before the fly can pierce through its incloſure. The nut falls with the leaves: and although you may imagine that the fly which lies within is loſt, yet in reality it is not ſo: on the contrary, its being covered up ſo cloſe, is the means of its preſervation. Thus it ſpends the winter in a warm houſe, where every crack and cranny of the nut is well ſtopped up; and lies buried as it were under a heap of leaves, which preſerves it from the injuries of the weather. This apartment, however, though ſo commodious a retreat in the winter, is a perfect priſon in the ſpring. The fly, rouſed out of its lethargy by the firſt heats, breaks its way through, and ranges where it pleaſes. A very ſmall aperture is ſufficient, ſince at this time the fly is but a diminutive creature. Beſides, the ringlets whereof its body is compoſed, dilate and become pliant in the paſſage. The male of this is a two-winged fly of a very particular kind. There ſeems a great reſemblance between theſe flies in all the *gall inſect* claſs, and that of the *peach gall inſect* may give a proper idea of all the reſt. This little creature, examined with the help even of the beſt glaſſes, ſhews, on the under part of its head, nothing analogous to the organs of other flies, deſtined to convey their nouriſhment; nothing that at all reſembles the trunks of the other two-winged flies, nor any thing that can be compared to teeth. The want of theſe organs is nothing ſingular in the inſect world, ſince the moths and butterflies afford us inſtances of it. Many of theſe may be ſeen, as ſoon as produced from their chryſalis, in a ſtate to propagate their ſpecies, and depoſit their eggs; and this great end atchieved, they have no farther occaſion for life, nor any means for its ſupport; and probably the caſe is the ſame with theſe flies, which as ſoon as looſe from their ſhell, ſeek out and fecundate the females, and have after this no farther uſe for life. It is another ſingularity in this ſpecies, that they are produced from their ſhell by their hinder part firſt; whereas all other ſpecies of the two-winged flies are produced with the forepart of their body firſt; and if we cannot ſay what may be the reaſons for this ſingularity in the production of this fly, we can however eaſily perceive that every thing is prepared and deſtined accordingly for it. In the nymphs of other flies, all the legs are conſtantly applied cloſe to the body, whereas on the contrary, in the nymph of the *gall inſect fly*, the legs placed next the head, or the firſt pair, are conſtantly ranged upward, and each of them embraces one ſide of the head; the conſtant poſition of theſe legs in this direction, is a proof that it is the order and courſe of nature in the production of the animal; nor is it without reaſon that they are thus placed in a ſpecies which, contrary to all others, is to force itſelf backward out of its ſhell, ſince they ſerve very properly for the creature to puſh himſelf backward by. Reaumur. Hiſt. Inſect. vol. iv. p. 40.

Gall-Bladder, *veſicula*, or *folliculus fellis*, is a membranous receptacle, in figure ſomewhat like a pear; ſituate at the lower margin of the liver, on the concave ſide; being about the bigneſs of a pullet's egg. For deſcription, ſee Syſtem of Anatomy, Part V. Sect. IX. For repreſentation, ſee Plate III. *Fig.* 4. let. C.

Gall-*Stones*, or thoſe concretions of earthy matter and bile that are found in the *gall* bladder, or bile ducts of beaſts, are uſed in the arts: when theſe are rubbed with water, and treated as *gamboge*, they yield a deep warm yellow, which, on account of its brightneſs and dark ſhade, as well as durableneſs, is very valuable. A fictitious kind of *gall-ſtones* may be prepared in the following manner; take a quart of the freſh bile of oxen; boil it with a quarter of an ounce of clear gum-arabic in a pewter veſſel in *balneo Mariæ*; evaporate the whole to about an eighth, and remove the remainder into a china cup or baſon, and evaporate it to dryneſs, collecting it into a maſs as it becomes of a ſtiff conſiſtence. This being more tranſparent, will be found of very great advantage in water-painting.

Oak-galls put, in a very ſmall quantity, into a ſolution of vitriol in water, though but a very weak one, give it a purple or violet colour; which, as it grows ſtronger, becomes black; and on this property depends the art of making our writing-ink, as alſo the arts of dying and dreſſing leather, and other manufactures. See Ink. Galls are very ſtrong aſtringents, and give out their aſtringent virtue very readily both to water and ſpirit. From two ounces of galls, 14 drachms of aſtringent extract were obtained by water, and between 12 and 13 with ſpirit. In medicine they are rarely uſed.

GALLANT, or **Galant**, a French term, ſignifying civil, polite, well-bred; or a perſon of wit and addreſs, who does every thing with a good grace: in fine, a civil perſon, ſomewhat brighter, gayer, and more agreeable than ordinary. It is difficult to define all the qualities annexed to the idea of a *gallant* man. It ſometimes implies one who has what the French call the *bon ton*; but it generally means one who has a great devotion for the fair ſex, with the manners adapted to pleaſe them. The French authors are very nice on this point; they diſtinguiſh *galant homme*, and *homme galant*.

GALLERY, in architecture, a covered place in a houſe, much longer than broad; and which is uſually placed in the wings of the buildings, and ſerves to walk in. The *galleries* of the Louvre are magnificent; a *gallery* of painting; a complete apartment is to conſiſt of a hall, ante chamber, chamber, cabinet and *gallery*. The *gallery* of a church is a kind of continued tribune, with a baluſtrade, built along the ſides, or lower-end of a church, to make it hold the more people; and, in the Greek churches, to ſeparate the women from the men.

Gallery, in fortification, a covered walk, or paſſage, made acroſs the ditch of a town beſieged, with timbers faſtened on the ground, and planked over.

GALLEY, a kind of low flat-built veſſel furniſhed with one deck, and navigated with ſails and oars, particularly in the Mediterranean. The largeſt ſort of theſe veſſels is employed only by the Venetians. They are commonly 162 feet long above, and 133 feet by the keel; 32 feet wide, with 23 feet length of ſtern-poſt. They are furniſhed with three maſts, and 32 banks of oars; every bank containing two oars, and every oar being managed by ſix or ſeven ſlaves, who are uſually chained thereto. In the fore part they have three little batteries of cannon. They are eſteemed extremely convenient for bombarding or making a deſcent upon an enemy's coaſt, as drawing but little water; and having by their oars frequently the advantage of a ſhip of war, in light winds or calms, by cannonading the latter near the ſurface of the water; by ſcouring her whole length with their ſhot, and at the ſame time keeping on her quarter or bow, ſo as to be out of the direction of her cannon. There are very few galleys now beſides theſe in the Mediterranean, which are found by experience to be of little utility except in fine weather; a circumſtance which renders their ſervice extremely precarious. They generally keep cloſe under the ſhore, but ſometimes venture out to ſea to perform a ſummer cruiſe. All the *galleys*, both antient and modern, are of a finer and ſlenderer make than ſhips. Formerly they made divers kinds; at preſent the *galleys* are all alike; all the difference between them is as to ſize, and nothing as to figure. They uſually keep towards the coaſts; though ſometimes they croſs the ſea.

Condemnation to the **Galleys**, is a penalty impoſed on criminals and delinquents, particularly in France; whereby they are adjudged to ſerve the king, or ſtate, as ſlaves on board the *galleys*, either for ever, or for a limited time.

Galley, in printing, a wooden frame, or inſtrument, formed of an oblong ſquare board, with a ledge on three ſides, and a groove to admit a falſe bottom called a galley ſlice, into which the compoſitor empties the letters out of his compoſing ſtick, as often as it is filled. The *galley*, when filled, contains the matter of one page; and when they have compoſed as many pages as are required for a whole ſheet, half ſheet, or the like, they impoſe them, i. e. they take the ſeveral pages out of the *galleys*; put them into a chaſe; lock them up with the furniture; and ſo make forms ready for the preſs. See Treatiſe on the Art of Printing.

GALLICISM, a phraſe or conſtruction, peculiar to the French language; or which has ſomething contrary to the ordinary rules of grammar or other languages. Thus, *Cet homme eſt ſur la bouche*, is a *Galliciſm*, having no regular conſtruction; and the ſame may be ſaid of *Fair de la terre le foſſe*; which no grammar could ever find out. With us it is uſed to denote ſuch phraſes or modes of ſpeech in Engliſh, as are formed after the French idiom.

GALLINÆ, in the Linnæan ſyſtem of ornithology, the name of a large order of birds, the general character of which is, that their beak is conic and bent; the upper mandible is arched, and extends beyond the lower; the noſtrils are half covered with a cartilaginous convex membrane; the feathers of the tails are more than twelve, and the feet are cloven; but the outermoſt and inner toes are connected by the firſt joint of the middle toe by a ſmall membrane. The DODO, PEACOCK, the *meleagris*, or TURKEY, the CRAX, the PHEASANT, the *meleagris Numida*, or GUINEA *Hen*, and TETRAO, are of this order. See Syſtem of ORNITHOLOGY.

GALLINACEOUS, in ornithology, the name of a ſpecies of birds of the pheaſant kind, including the common cock and hen, the characters of which are theſe. The beak is ſhort, ſtrong, and a little crooked, proper for the picking up of corn, which is the food of the whole ſpecies; the body is large, thick, and fleſhy; the wings are ſhort and hollowed, and not calculated for much flying; they all breed a numerous progeny; they build on the ground; the young are not fed by the parent, but immediately ſhift for themſelves; and ſome have long ſpurs behind their legs. See Syſtem of ORNITHOLOGY.

GALLING, in medicine, *Intertrigo*. Children are ſubject to inflammations and excoriations in ſeveral parts of their bodies, particularly behind the ears, in the neck, and thighs. Thoſe in the lower parts uſually proceed from the acrimony of the urine, which ſometimes frets off the epidermis, and leaves the cutis bare. The cure may be accompliſhed by waſhing the parts gently with warm water, twice or thrice a day, which diſſolves and drinks up the acrimonious ſalts of the urine lodged therein. Nurſes uſually diſſolve a little fuller's earth in the water, and apply it to the part after being well waſhed. Ceruſs, chalk, or calcined ſlate, finely powdered, will alſo ſerve for the ſame purpoſe. But where the inflammation and excoriation are conſiderable, it is proper to uſe, by way of fomentation, a ſolution of *trochiſcii albi Rhaſis*, in plantain water, twice or thrice a day. In the mean time the parts ſhould by all means be kept dry; or prevented from rubbing againſt each other, by the interpoſition of fine linen rags, or the uſe of a little red deſiccative ointment, or diapompholygos, ſpread thin upon it. James's Med. Dict.

GALLION, or GALLEON, in naval affairs, a ſort of ſhips employed in the commerce of the Weſt Indies. The Spaniards ſend annually two fleets; the one for Mexico, which they call the *flota*, and the other for Peru which they call the *gallions*. See FLOTA. By a general regulation made in Spain, it has been eſtabliſhed, that there ſhould be twelve men of war, and five tenders, annually fitted out for the armada or galleons; eight ſhips of ſix hundred tons burden each, and three tenders, one of an hundred ton, for the iſland Margarita, and two of eighty each; to follow the armada; for the New Spain fleet, two ſhips of ſix hundred tons each, and two tenders of eighty each; and for the Honduras fleet, two ſhips of five hundred tons each; and, in caſe no fleet happened to ſail any year, three gallions and a tender ſhould be ſent to New Spain for the plate. They are appointed to ſail from Cadiz in January, that they may arrive at Porto-Bello about the middle of April; where, the fair being over, they may take aboard the plate, and be at Havannah with it about the middle of June; where they are joined by the flota, that they may return to Spain with the greater ſafety.

GALLIOT, a ſmall galley or a ſort of brigantine, built very ſlightly, and deſigned only for chaſe. She hath but one maſt, and can both ſail and row. She uſually carries two or three pattereroes, and hath ſixteen or twenty oars. Some call the bombketches, *galliots*.

GALLON, an Engliſh meaſure, for things both liquid and dry, containing two pottles, or four quarts. The *gallon* always contains eight pints, or four quarts; but thoſe pints and quarts, and conſequently the *gallon* itſelf are different, according to the quality of the things meaſured: the wine *gallon*, for inſtance, contains 231 cubic inches, and holds eight pounds, avoirdupois, of pure water; the beer, and ale *gallon*, contain 282 ſolid inches, and holds ten pounds three ounces and a quarter; and the *gallon* for grains, meals, &c. 272¼ inches, and holds nine pounds thirteen ounces of pure water. See MEASURE.

GALLOWAYS, is the name of a peculiar ſort of horſes, ſo called from the county of Galloway in Scotland, where they are bred. Tradition reports that this kind of horſes ſprung from ſome Spaniſh ſtallions, which ſwam on ſhore from ſome of the ſhips of the famous Spaniſh armada, wrecked on the coaſt; and coupling with the mares of the country, furniſhed the kingdom with their poſterity. They were much eſteemed, and of a middling ſize, ſtrong, active, nervous, and hardy.

GALLOWS, an inſtrument of puniſhment, whereon perſons convicted capitally of felony, &c. are executed by hanging. Among our anceſtors it was called *furca*, a *fork*; a name by which it is ſtill denominated abroad, particularly in France and Italy. In this latter country, the reaſon of the name ſtill ſubſiſts; the *gallows* being a real fork driven into the ground, acroſs the legs, whereof is laid a beam to which the rope is tied.

GALLUS, or COCK, in ornithology. See PHASIANUS.

GAMBOGE, is a concreted vegetable juice, the produce of two trees, both called by the Indians *caracapulli*, and is partly of a gummy and partly of a reſinous nature. It is brought to us either in form of orbicular maſſes, or of cylindrical rolls of various ſizes; and is of a denſe, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the Eaſt Indies, called alſo *Cambodja*, and *Cambogia*; and from thence it has obtained its names of *cambadium*, *cambogium*, and *gambogium*. As a pigment, it makes a beautiful yellow, which is much uſed by the painters. Dr. Lewis ſays, that it makes a beautiful and durable citron-yellow ſtain upon marble, whether rubbed in ſubſtance on the hot ſtone, or applied, as dragon's-blood ſometimes is, in form of a ſpirituous tincture. When it is applied on cold marble, the ſtone is afterwards to be heated, to make the colour penetrate. Gamboge is commonly called a *gum*, but improperly. It appears to be wholly reſinous or ſulphureous; ſince ſpirit of wine diſſolves it almoſt entirely, and water, though it ſeparates its parts and keeps them ſuſpended, yet does not diſſolve them at all, nor is by any means a ſolvent for it. It is alſo very inflammable, and melts with a very gentle heat. If mixed with an equal quantity of ſalt of tartar, it readily diſſolves in common water by a few hours digeſtion. This ſolution, if kept over the fire, ſoon becomes a ſort of ſmooth glue or jelly. This is ſometimes done with a view to correct the deleterious qualities of gamboge taken inwardly, in which caſe it occaſions violent vomitings and purgings. But the moſt effectual method of correcting this and other reſinous purgatives, is by triturating them well with three or four times their weight of white ſugar, by which means they are rendered ſoluble in water, and incapable of adhering to the villous coats of the inteſtines.

GAME, in general, ſignifies any diverſion, or ſport, that is performed with regularity, and reſtrained to certain rules. See GAMING. Games are uſually diſtinguiſhed into thoſe of exerciſe and addreſs, and thoſe of hazard. To the firſt belong cheſs, tennis, billiards, &c. and to the latter thoſe performed with cards or dice, as backgammon, ombre, picquet, whiſt, &c. Games, in antiquity, were public diverſions, exhibited on ſolemn occaſions. Such, among the Greeks, were the Olympic, Pythian, Iſthmian, Nemean, &c. games; and, among the Romans, the Apollinarian, Circenſian, Capitoline, &c. games. See OLYMPIC, PYTHIAN, &c.

GAME, in law, ſignifies birds, or prey, taken or killed by fowling or hunting. The property of ſuch animals *feræ naturæ* as are known under the denomination of *game*, with the right of purſuing, taking, and deſtroying them, is veſted in the king alone, and from him derived to ſuch of his ſubjects as have received the grants of a chace, a park, or a free warren.

By the law of nature, indeed, every man, from the prince to the peaſant, has an equal right of purſuing, and taking to his own uſe all ſuch creatures as are *feræ naturæ*, and therefore the property of nobody, and very liable to be ſeiſed by the firſt occupant. But it follows from the very end and conſtitution of ſociety, that this natural right, as well as many others belonging to man as an individual, may be reſtrained by poſitive laws enacted for reaſons of ſtate, or for the ſuppoſed benefit of the community. This reſtriction may be either with reſpect to the place in which this right may, or may not, be exerciſed; with reſpect to the animals that are the ſubjects of this right; or with reſpect to the perſons allowed or forbidden to exerciſe it. And, in conſequence of this authority, we find that the municipal laws of many nations have exerted ſuch power of reſtraint; have in general forbidden the entering on another man's grounds, for any cauſe, without the owner's leave; have extended their protection to ſuch particular animals as are uſually the objects of purſuit; and have inveſted the prerogative of hunting and taking ſuch animals, in the ſovereign of the ſtate only, and ſuch as he ſhall authorize. Many reaſons have concurred for making theſe conſtitutions: as, 1. For the encouragement of agriculture and improvement of lands, by giving every man an excluſive dominion over his own ſoil. 2. For the preſervation of the ſeveral ſpecies of theſe animals, which would ſoon be extirpated by a general liberty. 3. For prevention of idleneſs and diſſipation in huſbandmen, artificers, and others of lower rank; which would be the unavoidable conſequence of univerſal licence. 4. For prevention of popular inſurrections and reſiſtance to the government, by diſarming the bulk of the people; which laſt is a reaſon oftener meant than avowed, by the makers of foreſt or game laws. Nor, certainly, in theſe prohibitions is there any natural injuſtice, as ſome have weakly enough ſuppoſed: ſince, as Puffendorf obſerves, the law does not hereby take from any man his preſent property, or what was already his own; but barely abridges him of one means of acquiring a future property, that of occupancy; which indeed the law of nature would allow him, but of which the laws of ſociety have in moſt inſtances very juſtly and reaſonably deprived him. Yet, however defenſible theſe proviſions in general may be, on the footing of reaſon, or juſtice, or civil policy, we muſt, notwithſtanding, acknowledge, that, in their preſent ſhape, they owe their immediate original to ſlavery. It is not till after the irruption of the northern nations into the Roman empire, that we read of any other prohibitions, than that natural one of not ſporting on any private grounds without the owner's leave.

With regard to the riſe and original of our preſent civil prohibitions, it will be found, that all foreſt and game laws were introduced into Europe at the ſame time, and by the ſame policy, as gave birth to the feodal ſyſtem; when thoſe ſwarms of barbarians iſſued from their northern hive and laid the foundation of moſt of the preſent kingdoms of Europe, on the ruins of the weſtern empire. For when a conquering general came to ſettle the œconomy of a vanquiſhed country, and to part it out among his ſoldiers or feudatories, who were to render him military ſervice for ſuch donations; it behoved him, in order to ſecure his new acquiſitions, to keep the *ruſtici* or native of the country, and all who were not his military tenants, in as low a condition as poſſible, and eſpecially to prohibit them the uſe of arms. Nothing could do this more effectually than a prohibition of hunting and ſporting: and therefore it was the policy of the conqueror to reſerve this right to himſelf, and ſuch on whom he ſhould beſtow it; which were only his capital feudatories, or greater barons. And, accordingly, we find, in the feudal conſtitutions, one and the ſame law prohibiting the *ruſtici* in general from carrying arms, and alſo proſcribing the uſe of nets, ſnares, or other engines for deſtroying the game. This excluſive privilege well ſuited the martial genius of the conquering troops, who delighted in a ſport which in its purſuit and ſlaughter bore ſome reſemblance to war. *Vita omnis* (ſays Cæſar, ſpeaking of the ancient Germans) *in venationibus atque in ſtudiis rei militaris conſiſtit.* And Tacitus in like manner obſerves, that *quoties bella non inuent; multum venatibus, plus per otium tranſigunt.* And indeed, like ſome of their modern ſucceſſors, they had no other amuſement to entertain their vacant hours; they deſpiſing all arts as effeminate, and having no other learning, than was couched in ſuch rude ditties as were ſung at the ſolemn carouſals which ſucceeded theſe ancient huntings. And it is remarkable, that, in thoſe nations where the feodal policy remains the moſt uncorrupted, the foreſt or game laws continue in their higheſt rigour. In France, all game is properly the king's; and in ſome parts of Germany it is death for a peaſant to be found hunting in the woods of the nobility.

With us in Britain, alſo, hunting has ever been eſteemed a moſt princely diverſion and exerciſe. The whole iſland was repleniſhed with all ſorts of game in the times of the Britons; who lived in a wild and paſtoral manner, without incloſing or improving their grounds; and derived much of their ſubſiſtence from the chaſe, which they all enjoyed in common. But, when huſbandry took place under the Saxon government, and lands began to be cultivated, improved, and encloſed, the beaſts naturally fled into the woody and deſart tracts; which were called the *foreſts*, and, having never been diſpoſed of in the firſt diſtribution of lands, were therefore held to belong to the crown. Theſe were filled with great plenty of game, which our royal ſportſmen reſerved for their own diverſion on pain of a pecuniary forfeiture on ſuch as interfered with their ſovereign. But every freeholder had the full liberty of ſporting upon his own territories provided he abſtained from the king's foreſts.

However, upon the Norman conqueſt, a new doctrine took place; and the right of purſuing and taking all beaſts of chaſe or venary, and ſuch other animals as were accounted *game*, was then held to belong to the king, or to ſuch only as were authoriſed under him. And this, as well upon the principles of the feodal law, that the king is the ultimate proprietor of all the lands in the kingdom, they being all held of him as the chief lord, or lord paramount of the fee; and that therefore he has the right of the univerſal ſoil, to enter thereon, and to chaſe and take ſuch creatures at his pleaſure: as alſo upon another maxim of the common law, that theſe animals are *bona vacantia,* and having no other owner, belong to the king by his prerogative. As therefore the former reaſon was held to veſt in the king a right to purſue and take them any where; the latter was ſuppoſed to give the king, and ſuch as he ſhould authorize, a *ſole* and *excluſive* right. This right, thus newly veſted in the crown, was exerted with the utmoſt rigour, at and after the time of the Norman eſtabliſhment; not only in the ancient foreſts, but in the new ones which the conqueror made, by laying together vaſt tracts of country, depopulated for that purpoſe, and reſerved ſolely for the king's royal diverſion; in which were exerciſed the moſt horrid tyrannies and oppreſſions, under colour of foreſt-law, for the ſake of preſerving the beaſts of chaſe; to kill any of which, within the limits of the foreſt, was as penal as the death of a man. And, in purſuance of the ſame principle, king John laid a total interdict upon the *winged* as well as the *fourfooted* creation: *capturam avium per totam Angliam interdixit.* The cruel and inſupportable hardſhips, which theſe foreſt laws created to the ſubject, occaſioned our anceſtors to be as zealous for their reformation, as for the relaxation of the feodal rigours and the other exactions introduced by the Norman family; and accordingly we find the immunities of *carta de foreſta* as warmly contended for, and extorted from the king with as much difficulty, as thoſe of *magna carta* itſelf. By this charter, confirmed in parliament, many foreſts were diſafforeſted, or ſtripped of their oppreſſive privileges, and regulations were made in the regimen of ſuch as remained; particularly killing the king's deer was made no longer a capital offence, but only puniſhed by a fine, impriſonment, or abjuration of the realm. And by a variety of ſubſequent ſtatutes, together with a long acquieſcence of the crown without exerting the foreſt-laws, this prerogative is now become no longer a grievance to the ſubject.

But, as the king reſerved to himſelf the *foreſts* for his own excluſive diverſion, ſo he granted out from time to time other tracts of lands to his ſubjects under the names of *chaſes* or *parks*; or gave them licence to make ſuch in their own grounds; which indeed are ſmaller foreſts in the hands of a ſubject, but not governed by foreſt-laws; and by the common law no perſon is at liberty to take or kill any beaſts of chaſe, but ſuch as hath an ancient chaſe or park; unleſs they be alſo beaſts of prey. As to all inferior ſpecies of game, called *beaſts and fowls of warren*; the liberty of taking or killing them is another franchiſe or royalty, derived likewiſe from the crown, and called *free-warren*; a word which ſignifies preſervation or cuſtody: as the excluſive liberty of taking and killing fiſh in a public ſtream or river is called a *free fiſhery*; of which, however, no new franchiſe can at preſent be granted, by the expreſs proviſion of *magna carta*, c. 16. The principal intention of granting a man theſe franchiſes or liberties was in order to protect the game, by giving him a ſole and excluſive power of killing it himſelf, provided he prevented other perſons. And no man, but he who has a chaſe or free warren, by grant from the crown, or preſcription, which ſuppoſes one, can juſtify hunting or ſporting upon another man's ſoil; nor indeed, in thorough ſtrictneſs of common law, either hunting or ſporting at all.

Upon the whole, it appears, that the king, by his prerogative, and ſuch perſons as have, under his authority, the royal *franchiſe* of *chace, park,* or *free-warren* are the *only* perſons who may acquire any property, however fugitive and tranſitory, in theſe animals *feræ naturæ*, while living; which is ſaid to be veſted in them *propter privilegium*. And it muſt alſo be obſerved, that ſuch perſons as may thus lawfully hunt, fiſh, or fowl, *ratione privilegii*, have only a qualified property in theſe animals; it not being abſolute or permanent, but laſting only ſo long as the creatures remain within the limits of ſuch reſpective franchiſe or liberty, and ceaſing the inſtant they voluntarily paſs out of it. It is held indeed, that if a man ſtarts any game within his own grounds, and follows it into another's, and kills it there, the property remains in himſelf. And this is grounded on reaſon and natural juſtice; for the property conſiſts in the poſſeſſion: which poſſeſſion commences by the finding it in his own liberty, and is continued by the immediate purſuit.

GAMING, the art of playing or practiſing any game, particularly thoſe of hazard; as cards, dice, tables, &c. Gaming has at all times been looked upon as a thing of pernicious conſequence to the commonwealth; and is therefore ſeverely prohibited by law. In China, *gaming* is equally prohibited by the common people, and the mandarins; and yet this does not hinder their playing and frequently loſing all they have; their lands, houſes, children, and even wives, which are all ſometimes laid on a ſingle card. F. le Compte. It is conſidered as a practice generally intended to ſupply, or retrieve, the expences occaſioned by *luxury*; it being a kind of tacit confeſſion, that the company engaged therein do, in general, exceed the bounds of their reſpective fortunes; and therefore they caſt lots to determine upon whom the ruin ſhall at preſent fall, that the reſt may be ſaved a little longer. But, taken in any light, it is an offence of the moſt alarming nature; tending, by neceſſary conſequence, to promote public idleneſs, theft, and debauchery, among thoſe of a lower claſs; and, among perſons of ſuperior rank, it hath frequently been attended with the ſudden ruin and deſolation of ancient and opulent families, an abandoned proſtitution of every principle of honour and virtue, and too often hath ended in ſelf-murder. To reſtrain this pernicious vice among the inferior ſort of people, the ſtatute 33 Hen. VIII. *c.* 9. was made; which prohibits, to all but gentlemen, the games of tennis, tables, cards, dice, bowls, and other unlawful diverſions there ſpecified, unleſs in the time of Chriſtmas, under pecuniary pains and impriſonment. And the ſame law, and alſo the ſtatute 30 Geo. II. *c.* 24. inflict pecuniary penalties, as well upon the maſter of any public houſe wherein ſervants are permitted to game, as upon the ſervants themſelves who are found to be gaming there. But this is not the principal ground of modern complaint; it is the gaming in high life, that demands the attention of the magiſtrate; a paſſion to which every valuable conſideration is made a ſacrifice, and which we ſeem to have inherited from our anceſtors the ancient Germans; whom Tacitus deſcribes to have been bewitched with the ſpirit of play to a moſt exorbitant degree. "They addict themſelves, (ſays he,) "to dice, (which is wonderful) when ſober, and as a ſerious employment; with ſuch a mad deſire of wining or loſing, that, when ſtript of every thing elſe, they will ſtake at laſt their liberty, and their very ſelves. The loſer goes into a voluntary ſlavery; and, though younger and ſtronger than his antagoniſt, ſuffers himſelf to be bound and ſold. And this perſeverance in ſo bad a cauſe they call the point of honour: *ea eſt in re prava pervicacia, ipſi fidem vocant.*" One would almoſt be tempted to think Tacitus was deſcribing a modern Engliſhman. When men are thus intoxicated with ſo frantic a ſpirit, laws will be of little avail; becauſe the ſame falſe ſenſe of honour, that prompts a man to ſacrifice himſelf, will deter him from appealing to the magiſtrate. Yet it is proper that laws ſhould be, and be known publicly, that gentlemen may conſider what penalties they wilfully incur, and what a confidence they repoſe in ſharpers; who, if ſucceſful in play, are certain to be paid with honour, or, if unſucceſsful, have it in their power to be ſtill greater gainers by informing. For, by ſtat. 16 Car. II. *c.* 7. if any perſon by playing or betting ſhall loſe more than 100*l.* at one time, he ſhall not be compellable to pay the ſame; and the winner ſhall forfeit treble the value, one moiety to the king, the other to the informer. The ſtatute 9 Ann. *c.* 14. enacts, that all bonds and other ſecurities, given for money won at play, or money lent at the time to play withal, ſhall be utterly void; that all mortgages and incumbrances of lands, made upon the ſame conſideration, ſhall be and enure to the heir of the mortgager; that, if any perſon at one time loſes 10*l.* at play, he may ſue the winner and recover it back by action of debt at law; and, in caſe the loſer does not, any other perſon may be the winner for treble the ſum ſo loſt; and the plaintiff in either caſe may examine the defendant himſelf upon oath; and that in any of theſe ſuits no privilege of parliament ſhall be allowed. The ſtatute, farther enacts, that if any perſon cheats at play, and at one time wins more than 10*l.* or any valuable thing, he may be indicted thereupon, and ſhall forfeit five times the value, ſhall be deemed infamous, and ſuffer ſuch corporal puniſhment as in caſe of wilful perjury. By ſeveral ſtatutes of the reign of king George II. all private lotteries by tickets, cards, or dice, (and particularly the games of faro, baſſet, ace of hearts, hazard, paſſage, and all other games with dice, except back-gammon) are prohibited under a penalty of 200*l.* for him that ſhall erect ſuch lotteries, and 50*l.* a-time for the players. Public lotteries, unleſs by authority of parliament, and all manner of ingenious devices, under the denomination of *ſales* or otherwiſe, which in the end are equivalent to lotteries, were before prohibited by a great variety of ſtatutes under heavy pecuniary penalties. But particular diſcriptions will ever be lame and deficient, unleſs all games of mere chance are at once prohibited; the invention of ſharpers being ſwifter than the puniſhment of the law, which only hunts them from one device to another. The ſtat. 13 Geo. II. *c.* 19. to prevent the multiplicity of horſe-races, another fund of gaming, directs, that no plates or matches under 50*l.* value ſhall be run, upon penalty of 200*l.* to be paid by the owner of each horſe running, and 100*l.* by ſuch as advertiſe the plate. By ſtatute 18 Geo. II. *c.* 34. the ſtatute 9 Ann. is farther enforced, and ſome deficiencies ſupplied; the forfeitures of that act may now be recovered in a court of equity; and, moreover, if any man be convicted, upon information or indictment, of winning or loſing at any ſitting 10*l.* or 20*l.* within 24 hours, he ſhall forfeit five times the ſum; Thus careful has the legiſlature been to prevent this deſtructive vice, which may ſhew that our laws againſt gaming are not ſo deficient. as ourſelves and our magiſtrates in putting thoſe laws in execution

Chance, or Hazard, in GAMING. Hazard, or chance, is a matter of mathematical conſideration, becauſe it admits of more and leſs. Gameſters either ſet out upon an equality of chance, or are ſuppoſed to do ſo. This equality may be altered in the courſe of the game, by the greater good-fortune or addreſs of one of the gameſters, whereby he comes to have a better chance, ſo that his ſhare in the ſtakes is proportionably better than at firſt. This more and leſs runs through all the ratios between equality and infinite difference, or from an infinitely little difference till it come to an infinite great one, whereby the game is determined. The whole game, therefore, with regard to the iſſue of it, is a chance of the proportion the two ſhares bear to each other.

CALCULATIVE TREATISE ON GAMING.

Calculations in Gaming and all other Events of a contingent nature, and for which there are certain Probabilities for happening or failing, come, in a mathematical conſideration, under what is termed the DOCTRINE OF CHANCE, which we ſhall here treat of.

It is the very nature of chance to be ignorant of its own operations and effects, and conſequently to be ever inconſtant and full of uncertainty, which renders it impoſſible to determine how any event, conſidered as merely under its blind and fickle direction, ſhall poſitively happen. But as the happening of any event has its previous degrees of probability or improbability, which appear within certain limits, it is the buſineſs of a mathematician to aſcertain thoſe bounds, and, by computation, to determine the exact meaſure of ſuch probability, or improbability.

This doctrine is extremely uſeful to perſons engaged in play, as thereby they may diſcover what advantage or diſadvantage each has in reſpect of the other, and how to manage their points with the leaſt riſk. It is alſo uſeful in calculating the value of Life Annuities and Reverſionary Eſtates; in forming plans for Benefit Societies and Lotteries; and in laying political ſchemes for the defence and ſafety of a nation. It may likewiſe be applied to a variety of other purpoſes too tedious to mention. In treating of the ſubject, I ſhall premiſe the following

DEFINITIONS.

1ſt. CHANCE. — An event which is brought about or effected by the mere operations of nature without any apparent *deſign* or *direction* of an *intelligent* agent is uſually attributed to CHANCE. Therefore chance has a natural but not a final cauſe.

2d. PROBABILITY, or IMPROBABILITY, of the happening of an event, is the number of ways or chances there are for the happening or failing of an event compared with the number of chances there are for both its happening and failing, and is expreſſed in a fractional manner, the chances denoting the probability or improbability being the numerator, and the total number of chances, the denominator. Thus if there are 5 poſſible ways for an event's happening, and 3 for its failing, the Probability of its happening will be $\frac{5}{5+3}$, or $\frac{5}{8}$; and the improbability, or probabity, of its failing will be $\frac{3}{5+3}$, or $\frac{3}{8}$. Likewiſe, if b be the chances for the happening of an event; and c the chances for its failing, then the probability of that event's happening will be $\frac{b}{b+c}$; and of its failing, $\frac{c}{b+c}$; where it is obvious that the probability of both happening and failing make together an unit, which therefore expreſſes a certainty; and hence, if the probability of an event be given, the improbability is alſo had by ſubtraction and vice verſa.

3d. ODDS, is a compare between the probability and improbability of an event. Thus, if there be 6 chances for the happening of an event, and but 4 for its failing, we ſay the odds in favour of its happening are 6 to 4, or 3 to 2.

4th. EXPECTATION in play, is the value of a man's chance in the thing played for, and is equal to the product of the abſolute value of the thing by the probability of obtaining it. Thus, if the real value of the prize be 1£. and my probability of obtaining it be $\frac{5}{8}$, the value of my chance, or my expectation, is 1£. × $\frac{5}{8}$ = $\frac{5}{8}$£. For EXPECTATION OF LIFE, ſee ANNUITIES, chap. II.

5th. ADVANTAGE, in play, is equal to the *expectation*, leſs the *ſtake*. Thus if the expectation is 5£. and the ſtake be 3£. the advantage in that ſituation is = 2£; this is the reverſe of *diſadvantage* in play, which is equal to the *ſtake*, leſs the *expectation*.

6th. RISK, is the value of the ſtake conſidered with reſpect to the probability of loſing it, and is equal to the product of ſuch probability by the real value of the ſtake. Thus if the ſtake be 5£. and the probability of winning be $\frac{5}{8}$, in that caſe the probability of loſing is $\frac{3}{8}$, and 5£. × $\frac{3}{8}$ = $\frac{15}{8}$£. = 1£. 17*s.* 6*d*; which therefore is equal to the true value of inſurance in ſuch a caſe.

7th. INDEPENDENT EVENTS, are ſuch as have no connection with each other; or, as that the happening of one neither promotes nor obſtructs the happening of the other. Thus if *A* undertakes with one die to throw an ace at two caſts, it is plain that the firſt caſt he has 1 chance to win and 5 to loſe; and the ſecond caſt he has alſo the very ſame, and conſequently the event of each caſt is independent of the other.

8th. DEPENDENT EVENTS, are ſuch, as the happening or failing of one, does in ſome meaſure promote or hinder the happening or failing of the other. Thus if A undertakes at two trials to draw the ace out of 13 cards of one ſuit; then at the firſt trial he has one chance to win and 12 to loſe, but if he miſſes in this, then the next trial he has 1 chance to win and only 11 to loſe, and ſo the ſecond event is affected by the firſt. In like manner if more trials were made each ſucceeding event would be affected by the preceding one, and therefore ſuch events are ſaid to be dependent.

SCHOLIUM. As 1 repreſents a certainty, or an infinitely great probability of the happening of an event, ſo $\frac{1}{2}$ repreſents an equal probability for happening or failing. For $1 - \frac{1}{2} = \frac{1}{2}$.

AXIOMS.

1ſt. In the computation of chances it is ſuppoſed, unleſs ſpecified to the contrary, that all the chances are equal to one another, or come up with equal facility.

2d. The whole expectation for any prize is equal to the ſum of all the expectations upon the particulars.

PROP. 1. The probability of the happening of ſeveral independent events is equal to the total probability, made by the product of the ſeveral probabilities of each. Thus, if $\frac{a}{a+b}$, $\frac{c}{c+d}$, $\frac{e}{e+f}$, &c. be the reſpective probabilities of ſeveral independent events; then the probability of their all happening will be $\frac{a}{a+b} \times, \frac{c}{c+d} \times \frac{e}{e+f} \times \&c. = \frac{ace, \&c.}{\overline{a+b} \times \overline{c+d} \times \overline{e+f}. \&c.}$ For ſuppoſe the 1ſt event to have already happened, then that the ſecond event ſhould alſo happen, the probability would be $\frac{c}{c+d}$, but before the play commences, the happening of the firſt event, not being a certainty (or 1) as here ſuppoſed, but only $\frac{a}{a+b}^{\,th}$ part thereof; therefore the probability, that both the firſt and ſecond event happens, will not be $\frac{c}{c+d}$, as above, but only the $\frac{a}{a+b}^{\,th}$ part of it, or $\frac{a}{a+b} \times \frac{c}{c+d} = \frac{ac}{\overline{a+b} \times \overline{c+d}}$. Again ſuppoſe both the firſt and ſecond events to have happened, then that the third event ſhould alſo happen, the probability would be $\frac{e}{e+f}$; but before the firſt event happens, the probability that both the firſt and ſecond happens is not a certainty as here ſuppoſed, but only $\frac{ac}{\overline{a+b} \times \overline{c+d}}^{\,th}$ part thereof, and conſequently the probability that all the three events happen is not $\frac{e}{e+f}$ but the $\frac{ac}{\overline{a+b} \times \overline{c+d}}^{\,th}$ part of $\frac{e}{c+f} = \frac{ace}{\overline{a+b}\times\overline{c+d}\times\overline{e+f}}$; and ſo on for 4 or more events, the whole probability being ever equal to the continual product of the reſpective probabilities of each.

Cor. 1. If a, c, e, &c. be the number of chances for happening, and b, d, f, &c. thoſe for failing, in three or more independent events. Then will $\overline{a+b}\times\overline{c+d}\times\overline{e+f}$, &c. be the number of all the chances or poſſible caſes, in which they can either happen or fail.

Cor. 2. In two ſuch events, the number of caſes for the happening of the firſt is $ac+ad$; for the failing thereof, $bc+bd$; for their both happening, ac; for the contrary, $ad+bc+bd$; for one happening, $ac+ad+bc$; for their both failing, bd; for the firſt happening and the latter failing, $ac+bc+bd$; and ſo for others.

Prop. 2. If a be the number of chances for the happening, and b thoſe for the failing of an event, the probability of its happening at leaſt t times in n trials will be $\frac{a^n + na^{n-1}b + n.\frac{1}{2}\overline{n-1}\,a^{n-2}b^2 +}{\overline{a+b}|^n}$ continued till the index of a be t.

For by the laſt propoſition and its corollaries, if a, b, and c, d, and e, f, &c. be the chances for happening and failing of three or more events, then the terms (of the multiplication) where a is concerned will be the numerator of a fraction, exhibiting the probability of the firſt event's happening. And the terms where both a and c are concerned, give the numerator of a fraction, ſhewing the probability of both the firſt and ſecond events happening, and ſo on; the denominator being $\overline{a+b}\times\overline{c+d}\times$, &c.

Now let the events denoted by the chances $c+d$ $e+f$, &c. be each the ſame as that denoted by $\overline{a+b}$, ſo will the continual product $\overline{a+b}\times\overline{c+d}\times\overline{e+f}$, &c. $= \overline{a+b}\times\overline{a+b}\times\overline{a+b}$, &c. $= \overline{a+b}|^n$; n, being the number of events, and c, e, &c. being each equal to a. In this point of view it is plain, that the happening of a and c is equivalent to the happening of a twice, and the happening of a, c, e, is equivolent to the hapening of a thrice, and ſo on. Therefore in the binomial $a+b$ raiſed to the power n, the terms with a, relate to the happening of the event once; thoſe with aa to its happening twice, and thoſe with a^3 to its happening thrice. Hence all the terms with a as far as a^t muſt be taken into the numerator for happening t times, and the denominator will be $\overline{a+b}^n$, and conſequently the fraction expreſſing the probability of happening t times in n, trials will be as above laid down.

Cor. 1. If a and b be the chances for the happening and failing of an event, then $1 - \overline{\frac{b}{a+b}}|^n$ will be the probability of its happening, and $\overline{\frac{b}{a+b}}|^n$ that of its failing once in n trials.

Prop. 3. If a perſon has an equal chance for the two prizes A and B, the value of his expectation is $\frac{A+B}{2}$. For the probability in each caſe being $\frac{1}{2}$, the expectation on the prize A is $= \frac{1}{2}A$; and the expectation on the prize B, is $\frac{1}{2}B$; and the value of the whole is $= \frac{1}{2}A + \frac{1}{2}B$, or $\frac{A+B}{2}$.

Like the probability of taking any one of three things, as A, B, C, (on equality of chance) is $\frac{1}{3}$; and the expection on A is $\frac{1}{3}A$; on B $= \frac{1}{3}B$; and on C, $= \frac{1}{3}C$; and the whole value $= \frac{1}{3}\times\overline{A+B+C}$. Alſo the expectation for four things, on the like equality, as A, B, C, D, is $\frac{A+B+C+D}{4}$; and ſo for others.

Prop. 4. If there be a chances for the prize A; and b chances for the prize B and no blanks, then the value of the expectation is $\frac{aA+bB}{a+b}$. For by definition 2, the probability of getting the prize A is $= \frac{a}{a+b}$, and of getting the prize B, $= \frac{b}{a+b}$; and by definition 4, the reſpective expectations are $\frac{aA}{a+b}$ and $\frac{bB}{a+b}$; and their ſum $= \frac{aA+bB}{a+b}$ as above.

Cor. In like manner, if there be 3 prizes A, B, C, and the chances for each be a, b, c, reſpectively, then the value of the whole expectation $= \frac{aA+bB+cC}{a+b+c}$ and ſo on.

Prop. 5. If a and b be two numbers of particular caſes relating to A and B reſpectively, and p, be ſome number of chances alike related to a and b; then the ſhare of p as belonging to A, is $\frac{a}{a+b}p$, and as belonging to B, is $\frac{b}{a+b}p$.

For ſince p is alike related to the whole a and b, it muſt be divided between them in proportion to the numbers a and b; the greater number having the greater ſhare, and the leſs number the leſs. Hence as $a+b : a :: p : \frac{a}{a+b}p$, the ſhare belonging to A; and as $a+b : b :: p : \frac{b}{a+b}p$, the ſhare belonging to B.

Cor. If there be ſeveral ſubjects, A, B, C, D, &c. whoſe numbers are a, b, c, d, &c. and the number of chances or things p, be alike related to them all; and if $\overline{a+b+c+d}$, &c. be put $= s$, then the ſhares of A, B, C, D, &c. are reſpectively $\frac{ap}{s}$, $\frac{bp}{s}$, $\frac{cp}{s}$, $\frac{dp}{s}$, &c.

Prop. 6. If a, be the chances for the happening, and b, thoſe for the failing of an event, to find at how many trials it is equally probable to happen or fail.

Let x be the number of trials, then (Cor. Prop. 2.) $\frac{1-b^x}{a+b^x} =$ the probability of happening, $=$ (per propoſition) $\frac{1}{2}$: whence $\overline{a+b}|^x = 2b^x$. And $x\times\log:\overline{a+b} = \log:2 + \overline{x\times\log:b.}$; and therefore $x\times\log:\overline{a+b} - \overline{x\times\log.b} = \log:2 = .30103$; and $x = \frac{.30103}{\log:\overline{a+b}-\log:b} = \frac{.30103}{\log:\frac{a+b}{b}}$.

Cor. 1ſt. If $a=b$ then $x=1$; for $\log:\frac{a+b}{b} = \log:\frac{2a}{a} = \log:2 = .30103$, and conſequently $x = \frac{.30103}{.30103} = 1$.

Cor. 2d. When b is very great in reſpect of a, Mr. Emerſon has ſhewn that x will be to $.693\times\frac{b}{a} = .7\frac{b}{a}$ nearly.

Cor. 3d. When b is very ſmall or nothing, then x becomes very ſmall or nothing. For if $1+\frac{a}{b} = 10, 100, 1000$, &c. then will $x = .3, \frac{3}{2}, \frac{.3}{3}$, &c.

Prop. 7th. If there be a chances for happening, and b chances for failing of an event at one trial, to find in how many trials it is equally probable or improbable to happen t times.

Put $x =$ the number of trials, the (by Prop. 2.) we ſhall have $\frac{a^x + xa^{x-1}b + x\frac{x-1}{2}a^{x-2}b^2 + \&c.}{\overline{a+b}|^x} = \frac{1}{2}$, the ſeries being continued till the index of a be equal to t; — or, make $\frac{b^x + xb^{x-1}a + x\frac{x-1}{2}b^{x-2}a^2 + \&c.}{\overline{a+b}|^x} = \frac{1}{2}$ continuing the ſeries till the index of a be $t, -1$; from either of which the value of x, may be found; the former ſeries however being more commodious when t is great; but when t is ſmall, the latter will claim the preference.

Having laid down the fundamental propoſitions of the doctrine of chances, I proceed to ſhew the application thereof in the ſolution of certain queſtions, referring thoſe who would wiſh to ſee the ſubject more copiouſly handled to that excellent treatiſe written by M. de Moivre, and the tracts of Meſſrs. Simpſon and Emerſon, on this ſubject.

THE APPLICATION OF CHANCE.

Question 1. If I have 3 chances for 4 ſhillings, 6 chances for 8 ſhillings, and 5 chances for 5 ſhillings, what is the value of my expectation, theſe 14 being all the chances poſſible?

By Prop. 3. *A*, *B*, and *C*, are reſpectively equal to 4, 8, and 5 ſhillings; and a, b, and c, $=$ 3, 6, 5, and therefore my expectation is worth $\frac{\overline{3\times4}+\overline{6\times8}+\overline{5\times5}}{14} = \frac{12+48+25}{14} = \frac{85}{14} = 6\frac{1}{14}$ ſhillings.

Question 2. To find the probability of throwing an ace in three caſts with one die; or which is the ſame, in one caſt with three dice.

By Prop. 2. put $a=1$, $b=5$, $n=3$ and $t=1$; and the general expreſſion will become $\frac{a^3+3a^2b+3ab^2}{\overline{a+b}|^3} = \frac{1+15+75}{216} = \frac{91}{216}$. the probability required; Or, $\frac{b^3}{\overline{a+b}|^3} = \frac{125}{216}$. $=$ the probability of failing, and therefore the probability of happening $= \frac{91}{216}$ as before.

Question 3. In how many caſts with one die may one undertake upon an even wager to throw an ace?

Let $x =$ the number of throws, $a =$ chance to hit $= 1$; $b =$ chances to miſs $= 5$. Then (per Cor. Prop. 2) $\frac{b^x}{\overline{a+q}|^x} =$ probability of failing, which (in an equal wager) is equal to the probability of happening: conſequently $\overline{\frac{b}{a+b}}|^x = \frac{1}{2}$; and $2b^x = \overline{a+b}|^x$. Whence the log 2, $+\overline{x\times\log.b} = x\times\log.\overline{a+b}$. Therefore $x = \frac{\text{Log. }2.}{\text{Log.}\,\overline{a+b}-\log.\,b} = \frac{\text{Log }2.}{\text{Log}:6.-\log:5.} = \frac{.30103}{.07918} = 3.82$; that is between 3 and 4 throws; or at four throws one may undertake on an even wager to throw an ace.

Lemma. To find the number of ways for throwing a given number of points with any number of dies? Let the given number of points $= p+1$, and $n =$ the number of dice, then the number of ways, according to Mr. Emerſon's laws of chance, will be

$$+\frac{p}{1}\times\frac{p-1}{2}\times\frac{p-2}{3}, \text{ \&c. (to } n-1 \text{ terms)}$$

$$-\frac{p-6}{1}\times\frac{p-7}{2}\times\frac{p-8}{3}, \text{ \&c.}\times\frac{n}{1}$$

$$+\frac{p-12}{1}\times\frac{p-13}{2}\times\frac{p-14}{3} \text{ \&c.}\times\frac{n}{1}\times\frac{n-1}{2}$$

$$-\frac{p-18}{1}\times\frac{p-19}{2}\times\frac{p-20}{3} \text{ \&c.}\times\frac{n}{1}\times\frac{n-1}{2}\times\frac{n-2}{3}$$

$$+ \text{ \&c.}$$

Which rows of ſeries muſt be continued downwards till ſome of the factors in each become *o*, or negative; taking $n-1$ terms in each. The demonſtration of a ſeries ſimilar to this may be ſeen in M. De Moivre's doctrines of chances, and in a treatiſe on this ſubject written by profeſſor Simpſon.

QUESTION 4. How many chances are there for throwing 16 with 4 dice?

Here $p=1$, and $n=4$, whence the above ſeries will be

$$+\tfrac{15}{1}\times\tfrac{14}{2}\times\tfrac{13}{3} = +455$$
$$-\tfrac{9}{1}\times\tfrac{8}{2}\times\tfrac{7}{3}\times\tfrac{4}{1} = -336$$
$$+\tfrac{3}{1}\times\tfrac{2}{2}\times\tfrac{1}{3}\times\tfrac{4}{1}\times\tfrac{3}{2} = +\ 6$$

Sum 125 the chances required; and the whole number of chances $=6^4=1296$.

QUESTION 5. *A* undertakes to throw 10 with three dice, before *B* throws 12 with four dice. What are the odds of the game?

1ſt. For the probability of caſting 10 with 3 dice; here $p=g$, and $n=3$; and conſequently (by the ſeries) the number of chances for throwing 10 are 27; and the whole number of chances $=6^3=216$; therefore the probabilty of throwing $10=\frac{27}{216}$.

2d. For the probability of caſting 12 with 4 dice. Here $p=11$ and $n=4$; and therefore the number of chances for throwing 12 will be found $=125$; and the whole number of chances being $6^4=1296$; the probability of throwing 12 is therefore $\frac{125}{1296}$.

Whence *A*'s chance is to that of *B*'s, as $\frac{27}{216}$ to $\frac{125}{1296}$, or in whole numbers, as 162 to 125, which are the true odd's in *A*'s favour.

QUESTION 6. Any number of dice being given, to find the probability of caſting two faces of a ſort at one throw?

The following general expreſſion for performing this, is given by Mr. Emerſon, and is deduced from the doctrine of combinations, of which we have treated in our new Syſtem of Arithmetic. If $n=$ the number of dice, then the probability of not caſting 2 faces of a ſort will be $\frac{6\times5\times4\text{ (to } n \text{ terms)}}{6\times6\times6\text{ (to } n \text{ terms)}}$, $=$ the probability of failing; and therefore the probability of performing it will be $1-\frac{6.5.4.}{6.6.6.}$ (to *n* terms.)

EXAMPLE. What is the probability of caſting 2 faces of a ſort, with 4 dice?

Here $\frac{6.5.4.3}{6.6.6.6}=\frac{360}{1296}$, the probability of failing; and $\frac{1296-360}{1296}=\frac{936}{1296}$, the probability of happening.

QUESTION 7. To find the probability of throwing *m* aces only, at *n* throw with 1 die, or at 1 throw with *n* dice. From the doctrine of combinations it is eaſy to demonſtrate that $\frac{n}{1}.\overline{\frac{n-1}{2}}.\overline{\frac{n-2}{3}}$ (to *m* terms) $\times\, 5^{n-m}$ is the number of all the caſes whereby *m* aces only can be caſt, and conſequently $\frac{n}{1}\cdot\frac{n-1}{2}\cdot\frac{n-2}{3}$ (to *m* terms) $\times\, \frac{5^{n-m}}{6^{n}}=$ the probability required.

EXAMPLE. Let $m=3$ and $n=10$, then $\frac{10}{1}, \frac{9}{2}, \frac{8}{3}, \times 5^7 = 120\times78125=9375000$, the number of chances for throwing 3 aces in 10 caſts, and the required probability is therefore $\frac{9375000}{6^{10}}$, $\frac{9375000}{60466176}=\frac{2}{3}$ nearly.

QUESTION 8. To find how many ways a perſon may caſt *p* aces, *q* duces, *r* trays, *s* fours, &c. (or any other faces) with *n* dice.

Anſwer, $\frac{1.2.3.4\text{ (to } n \text{ terms)}}{1.2.3.\text{ (to } p \text{ terms)} \times 1.2.3\text{ (to } q \text{ terms)} \times 1.2\ 3\text{ (to } r \text{ terms) \&c.}}$

EXAMPLE. How many ways can 3 aces, 2 duces, 1 tray, and 1 four, be caſt with 7 dice; Here $p=3$, $q=2$, $r=1$, $s=1$, $n=7$, which ſubſtituted in the above general expreſſion, we have $\frac{1.2.3.\ 4.\ 5.\ 6.\ 7}{1.2.3.\times1.2.\times1.\times1}=420$ the Anſwer, and $6^7=279936$ being the whole number of chances on 7 dice, the probability of performing the above at 1 throw, is $\frac{420}{279936}=\frac{2}{1333}$ nearly.

QUESTION 9. *A* and *B* playing together, *A* wants 2 games of winning the ſet, and *B* wants 3 games of it. What are the odds in favour of *A*?

It is evident the play will be ended in four games at moſt; therefore raiſe a binomial as $a+b$ to the fourth power, $=a^4+4a^3b+6a^2b^2+4ab^3+b^4$, and take the coefficients of all the terms wherein the power of *a* is 2 or more, for the chances of A, $=1+4+6=11$, and the coefficients of all the terms in which the power of *b* is 3 or more, for the chances of B $=1+4=5$; then the odds in A's favour are as 11 to 5; and the probability of A's winning is $\frac{11}{16}$, and that of B's $\frac{5}{16}$.

QUESTION 10. Suppoſing the ſame caſe as the laſt, but with this conſideration, that *A*'s ſkill is to that of *B*'s, in proportion of 4 to 3, what are the odds of the game? Here in the above involved binomial, make $a=4$, and $b=3$; and inſtead of the coefficients take the terms themſelves; and ſo the chances in *A*'s favour are 1888, and in *B*'s favour 513, which numbers denote the true proportion of the odds.

QUESTION 11. A gentleman at whiſt undertakes to pay a guinea every time the dealer has the moſt trumps, on condition of receiving a crown whenever any one of the reſt ſhall have more trumps than the dealer; *Quere*, whether he has the advantage or diſadvantage, and how much?

Here the probability of any one card's proving a trump (ſave the laſt) is $\frac{12}{51}$. But with regard to the laſt card, it is a certainty, or $\frac{51}{51}$. Therefore, rejecting the denominator which is common, the dealer has 12 cards of 12 chances each, and 1 card of 51 chances $=$ in the whole 195: and each of the reſt has 13 cards of 12 chances each $=$ in the whole 156. Whence it appears that the dealer has an expectation in point of trumps above any other player alone, in the ratio of 195 to 156, or of 5 to 4. But in the preſent caſe, the other three players are collectively oppoſed to him. Now $\frac{5}{9}$ being his probability againſt any one player, it is plain that $\left.\frac{5}{9}\right|^{3}=$ his probability againſt the whole $=\frac{125}{729}$. Conſequently, the odds againſt the dealer's winning, are 604 to 125; or as 24 to 5 nearly. In money, as one guinea to 4*s.* 4*d.* And the gentleman's advantage every deal, is equal to 8*d.* $\times\frac{604}{729}=$ 6*d.* $\frac{3}{4}$, nearly.

QUESTION 12. In a lottery of 100000 tickets, of which 90000 are blanks, and the reſt prizes, it is required to determine the probability of having a prize among the firſt ſix tickets.

Here the probability of the firſt tickets failing $=\frac{9}{10}$, and of the firſt and ſecond's failing $\frac{9}{10}\times\frac{89999}{99999}$; of the firſt, ſecond and third failing $\frac{9}{10}\times\frac{89999}{99999}\times\frac{89998}{99998}$, &c.; and laſtly, their all ſix failing $\frac{9}{10}\times\frac{89999}{99999}\times\frac{89998}{99998}\times\frac{89997}{99997}\times\frac{89996}{99996}\times\frac{89995}{99995}$; which fractions being actuallly multiplied, (and that is eaſily done by logarithms) we have the product $=.53143$, the probability of failing, and conſequently its complement $=.46857$, the probability of taking one prize, or more, in 6 tickets.

QUESTION 13. To find at hazard the advantage of the ſetter upon all ſuppoſitions of main and chance?

1ſt. Let it be ſuppoſed that the main is VII; then if the chance of the caſtor be VI or VIII, the ſetter will have 6 chances to win, and 5 to loſe, and his expectations will be $\frac{6}{11}$ of the ſtake, but the probability of the ſetter's chance being VI. or VIII. is only $\frac{10}{36}$, and therefore $\frac{10}{36}\times\frac{6}{11}=\frac{5}{33}=$ his expectation.

2d. If the chance of the caſtor be 5 or 9, when the main is VII.; the expectation of the ſetter will be $\frac{24}{5\times36}=\frac{2}{15}$.

3d. If the chance of the caſtor be IV. or X. the expectation of the ſetter will be $\frac{4}{36}$ or $\frac{1}{9}$.

4th. The main being as before, if the caſtor ſhould throw II. III. or XII. then the ſetter would of courſe win, but there being 4 chances for throwing II. III. or XII. it follows that before the caſtor has thrown, the expectation of the ſetter, as reſulting from the probability of the caſtor's being II. III. or XII. will be $\frac{4}{36}=\frac{1}{9}$.

Laſtly, if the caſtor ſhould throw VII. or XI. the ſetter loſes his expectation.

From the foregoing caſes, the main being VII. it follows that the expectation of the ſetter $=\frac{5}{33}+\frac{2}{15}+\frac{1}{9}+\frac{1}{9}=\frac{251}{495}$, and conſequently the expectation of the caſtor $=1-\frac{251}{495}=\frac{244}{495}$. Hence the odds for winning is in favour of the ſetter, as 251 to 244; and his gain therefore $=\frac{7}{495}=$ about 3*d.* $\frac{1}{2}$ in a guinea. By a like proceſs, it will be found that when the main is VI. or VIII. the gain of the ſetter will be $\frac{167}{7128}$; ſomething more than 5*d.* $\frac{3}{4}$ in a guinea.

When the main is V. or IX. the gain of the ſetter, is $\frac{43}{2835}=$ about 3*d.* $\frac{3}{4}$ in a guinea; ſo that in each caſe the ſetter has the advantage, and before a main is thrown, the expectation of his advantage amounts to about 4*d.* $\frac{1}{2}$ in a guinea.

COR. The probability of a main is to the probability of no main, as 111 to 107.

Mr. Emerſon, at the concluſion of his treatiſe, draws this inference, that chance, on account of its perpetual approximation to ſome certain law, very little diſturbs ſuch events as *were deſigned to happen by ſome determinate law*, and ſays, that it is wonderful to obſerve how regularity ariſes out of irregularity, and order out of diſorder. He adds, we may conclude, that all ſuch laws, by which the various effects and productions of *chance* are regulated, are the effects of *intelligence* and *deſign*, and were conſtituted by ſome *powerful agent*, and *intended* to ſerve *wiſe* and *uſeful purpoſes*; neceſſary for the *preſervation*, *order* and *œconomy* of the *Univerſe*. So the Great Author of Nature can make *even Chance* execute his deſigns.

The doctrine of Chances may be applied to the aſcertaining of the probabilities and odds in all poſſible occurrences of Gaming, or Riſk, provided the principles of the caſe are rightly underſtood. But in ſome inſtances, the calculations are extremely intricate; and require the utmoſt invention and ſubtle penetration to manage them properly; and therefore thoſe who wiſh to excel in calculations of this kind, ſhould firſt acquire a ſtrict and true method of reaſoning, admitting of nothing as fact what carries with it it's due evidence; and then perfect themſelves in the various kinds of algebraic operations, and the doctrine of infinite ſeries, &c. which done, I am perſuaded that by carefully going through this ſhort fundamental Treatiſe, they will be enabled, without further inſtruction, to purſue the ſubject to any extent, let the matter be as difficult as it may; but without thoſe previous accompliſhments, nothing of conſequence can be ſucceſsfully undertaken.

EXCISE OFFICE,
BROAD STREET.

ROBERT MOODY.

TREATISE ON GARDENING.

GARDENING, in the perfection to which it has been lately brought in Britain, is entitled to a place of conſiderable rank among the liberal arts. It is as ſuperior to landſcape-painting, as a reality to a repreſentation: it is an exertion of fancy; a ſubject for taſte; and being releaſed now from the reſtraints of regularity, and enlarged beyond the purpoſes of domeſtic convenience, the moſt beautiful, the moſt ſimple, the moſt noble ſcenes of nature, are all within its province. For it is no longer confined to the ſpots from which it takes its name; but regulates alſo the diſpoſition and embelliſhments of a park, a farm, or a riding; and the buſineſs of a gardener is to ſelect and apply whatever is great, elegant, or characteriſtic, in any of them; to diſcover and to ſhew all the advantages of the place upon which he is employed; to ſupply its defects, to correct its faults, and to improve its beauties. For all theſe operations, the objects of nature are ſtill his only materials. His firſt inquiry, therefore, muſt be into the means by which thoſe effects are attained in nature, which he is to produce; and into thoſe properties in the objects of nature, which ſhould determine him in the choice and arrangement of them.

In the choice, of a place proper for a garden, the moſt eſſential points to be conſidered are the ſituation, the ſoil, the expoſure, water and proſpect.

1ſt, As to the ſituation, it ought to be ſuch a one as is wholeſome, and in a place neither too high nor too low; for if a garden be too high, it will be expoſed to the winds, which are very prejudicial to trees; and if it be too low, the dampneſs, the vermin, and the venomous creatures that breed in ponds and marſhy places, add much to their inſalubrity. The moſt happy ſituation is on the ſide of a hill, eſpecially if the ſlope be eaſy, and in a manner imperceptible; if a good deal of level ground be near the houſe; and if it abounds with ſprings of water; for, being ſheltered from the fury of the winds, and the violent heat of the ſun, a temperate air will be there enjoyed; and the water that deſcends from the top of the hill, either from ſprings or rain, will not only ſupply fountains, canals, and caſcades for ornament, but, when it has performed its office, will water the adjacent valleys, and, if it be not ſuffered to ſtagnate, will render them fertile and wholeſome. Indeed, if the declivity of the hill be too ſteep, and the water be too abundant, a garden on the ſide of it may frequently ſuffer, by having trees torn up by torrents and floods; and by the tumbling down of the earth above, the walls may be demoliſhed, and the walks ſpoiled. It cannot, however, be denied, that the ſituation on a plain or flat has ſeveral advantages which the higher ſituation has not; for floods and rain commit no damage; there is a continued proſpect of champaigns, interſected by rivers, ponds, and brooks, meadows, and hills covered with woods or buildings: beſides, the level ſurface is leſs tireſome to walk on, and leſs chargeable than that on the ſide of an hill, ſince terrace-walks and ſteps are not there neceſſary: but the greateſt diſadvantage of flat gardens, is the want of thoſe extenſive proſpects which riſing grounds afford.

2dly, A good earth or ſoil is next to be conſidered; for it is ſcarce poſſible to make a fine garden in a bad ſoil. There are indeed ways to meliorate ground, but they are very expenſive; and ſometimes, when the expence has been beſtowed of laying good earth three feet deep over the whole ſurface, a whole garden has been ruined, when the roots of the trees have come to reach the natural bottom. To judge of the quality of the ſoil, obſerve whether there be any heath, thiſtles, or ſuch-like weeds growing ſpontaneouſly in it; for they are certain ſigns that the ground is poor. Or if there be large trees growing thereabouts, obſerve, whether they grow crooked, ill-ſhaped, and grubby, and whether they are of a faded green, and full of moſs, or infeſted with vermin; if this be the caſe, the place is to be rejected; but, on the contrary, if it be covered with good graſs fit for paſture, you may then be encouraged to try the depth of the ſoil. To know this, dig holes in ſeveral places, ſix feet wide, and four deep; and if you find three feet of good earth, it will do very well; but leſs than two will not be ſufficient. The quality of good ground is, neither to be ſtony, nor too hard to work; neither too dry, too moiſt, nor too ſandy and light; nor too ſtrong and clayey, which is the worſt of all for gardens.

3dly, The next requiſite is water; the want of which is one of he greateſt inconveniencies that can attend a garden, and will bring certain mortality upon whatever is planted in it, eſpecially in the reater droughts that often happen in a hot and dry ſituation in ſummer; beſides its uſefulneſs in fine gardens for making fountains, anals, caſcades, &c. which are the greateſt ornaments of a garden.

4thly, The laſt thing to be conſidered, is the proſpect of a fine ountry; and though this is not ſo abſolutely neceſſary as water, et it is one of the moſt agreeable beauties of a fine garden: beſides, a garden be planted in a low place that has no kind of proſpect, it ill not only be diſagreeable, but unwholeſome. In the laying out nd planting of gardens the beauties of nature ſhould always be udied: for the nearer a garden approaches to nature, the longer it ill pleaſe. The area of a handſome garden, may take up thirty r forty acres, but not more; and the following rules ſhould be obrved in the diſpoſition of it. There ought always to be a deſcent f at leaſt three ſteps from the houſe to the garden; this will render e houſe more dry and wholeſome, and the proſpect on entering the arden more extenſive. The firſt thing that ought to preſent itſelf view, ſhould be an open lawn of graſs, which ought to be conſiderably broader than the front of the building; and if the depth be one half more than the width, it will have a better effect; if on the ſides of the lawn there are trees planted irregularly, by way of open groves, the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn ſhould be ſurrounded with a gravel walk, on the outſide of which ſhould be borders three or four feet wide, for flowers; and from the back of theſe the proſpect will be agreeably terminated by a ſlope of ever-green ſhrubs; which, however, ſhould never be ſuffered to exclude agreeable proſpects, or the view of handſome buildings. Theſe walks may lead through the different plantations, gently winding about in an eaſy natural manner; which will be more agreeable than either thoſe long ſtraight walks, too frequently ſeen in gardens, or thoſe ſerpentine windings, that are twiſted about into ſo many ſhort turns, as to render it difficult to walk in them: and as no garden can be pleaſing where there is a want of ſhade and ſhelter, theſe walks ſhould lead as ſoon as poſſible into plantations, where perſons may walk in private, and be ſheltered from the wind. Where the borders of the gardens are fenced with walls or pales, they ſhould be concealed with plantations of flowering ſhrubs, intermixed with laurels and other ever-greens; which will have a good effect, and at the ſame time conceal the fences, which are diſagreeable when left naked and expoſed to the ſight. Groves are the moſt agreeable parts of a garden, ſo that there cannot be too many of them; only that they muſt not be too near the houſe, nor be ſuffered to block up agreeable proſpects. To accompany parterres, groves opened in compartments, quincunxes, and arbour-work with fountains, &c. are very agreeable. Some groves of ever-greens ſhould be planted in proper places, and ſome ſquares of trees of this kind may alſo be planted among the other wood.

Narrow rivulets, if they have a conſtant ſtream, and are judiciouſly led about a garden, have a better effect than many of the large ſtagnating ponds or canals, ſo ftequently made in large gardens. When wilderneſſes are intended they ſhould not be cut into ſtars and other ridiculous figures, nor formed into mazes or labyrinths, which in a great deſign appear trifling. Buildings, ſtatues, and vaſes, appear very beautiful; but they ſhould never be placed too near each other: magnificent fountains are alſo very ornamental; but they ought never to be introduced, except there be water to keep them conſtantly running. The ſame may alſo be obſerved of caſcades and other falls of water.

In ſhort, the ſeveral parts of a garden ſhould be diverſified; but in places where the eye takes in the whole at once, the two ſides ſhould be always the ſame. In the buſineſs of deſigns, the aim ſhould be always at what is natural, great, and noble. The general diſpoſition of a garden, and of its parts, ought to be accommodated to the different ſituations of the ground, to humour its inequalities, to proportion the number and ſorts of trees and ſhrubs to each part, and to ſhut out from the view of the garden no objects that may become ornamental. And before a garden is planned out, it ought ever to be conſidered, what it will be when the trees have had 20 years growth. But for a more extended view of this ſubject, ſee the following general diſplay.

PART I. ORNAMENTAL GARDENING.

ARTICLE I. THE CONSTITUENT PARTS OF THE SCENES OF NATURE.

Nature, always ſimple, employs but four materials in the compoſition of her ſcenes; *ground, wood, water, and rocks.* The cultivation of nature has introduced a fifth ſpecies, the *buildings* requiſite for the accommodation of men. Each of theſe again admits of varieties in figure, dimenſion, colour, and ſituation. Every landſcape is compoſed of theſe parts only; every beauty in a landſcape depends on the application of their ſeveral varieties.

SECT. I. GROUND.

The ſhape of ground muſt be either a *convex*, a *concave*, or a *plane*; in terms leſs technical called a *ſwell*, a *hollow*, and a *level*. By combinations of theſe are formed all the irregularities of which ground is capable; and the beauty of it depends on the degrees and the proportions in which they are blended.

Of a Level Ground.

Both the convex and the concave are forms in themſelves of more variety, and may therefore be admitted to a greater extent than a plane. But levels are not totally inadmiſſible. The preference unjuſtly ſhewn to them in the old gardens, where they prevailed almoſt in excluſion of every other form, has raiſed a prejudice againſt them.

It is frequently reckoned an excellence in a piece of made ground, that every part of it is uneven; but then it wants one of the three great varieties of ground, which may ſometimes be intermixed with the other two. A gentle concave declivity falls and ſpreads eaſily on a flat; the channels between ſeveral ſwells degenerate into mere gutters, if ſome breadth be not given to the bottoms by flattening them; and in many other inſtances, ſmall portions of an inclined or horizontal plane may be introduced into an irregular compoſition. Care only muſt be taken to keep them down as ſubordinate parts, and not to ſuffer them to become principal.

There are, however, occaſions on which a plane may be principal: a hanging level often produces effects not otherwiſe attainable. A large dead flat, indeed, raiſes no other idea than of ſafety:

the eye finds no amuſement, no repoſe on ſuch a level: it is fatigued, unleſs timely relieved by an adequate termination; and the ſtrength of that termination will compenſate for its diſtance. The greatneſs and the beauty of the boundary are not, however, alone ſufficient; the form of it is of ſtill more conſequence. A continued range of the nobleſt wood, or the fineſt hill, would not cure the inſipidity of a flat: a leſs importment, a leſs pleaſing boundary, would be more effectual, if it traced a more varied outline; if it advanced ſometimes boldly forward, ſometimes retired into deep receſſes; broke all the ſides into nine parts, and marked even the plain itſelf with irregularity.

Convex or Concave Shapes of Ground.

A plain is not, however, in itſelf intereſting; and the leaſt deviation from the uniformity of its ſurface changes its nature: as long as the flat remains, it depends on the objects around for all its variety, and all its beauty. But convex and concave forms are generally pleaſing, and the number of degrees and combinations into which they may be caſt is infinite: thoſe forms only in each which are perfectly regular muſt be avoided. A ſemicircle can never be tolerable: ſmall portions of large circles blended together, or lines gently curved, which are not parts of any circle, a hollow ſinking, but little below a level, and ſwell very much, flattened at the top, are commonly the moſt agreeable figures. There are, however, ſituations where the convex form ſhould be preferred: a hollow juſt below the brow of a hill reduces it to a narrow ridge, which has a poor meagre appearance; and an abrupt fall will never ſeem to join with a concave form immediately above it: a ſharp edge divides them; and to connect them, that edge muſt be rounded, or at leaſt flattened; which, is, in fact, to interpoſe a convex or a level.

Connection between the Parts in Ground.

In made ground, the connection is, perhaps, the principal conſideration. A ſwell which wants it is but a heap, a hollow but a hole, and both appear artificial: the one ſeems placed upon a ſurface to which it does not belong; the other, dug into it. On the great ſcale of nature, indeed, either may be ſo conſiderable in itſelf, as to make its relation to any other almoſt a matter of indifference; but, on the ſmaller ſcale of a garden, if the parts are disjointed, the effect of the whole is loſt; and the union of all is not more than ſufficient to preſerve an idea of greatneſs and importance, to ſpots which muſt be varied, and cannot be ſpacious. Little inequalities are beſides in nature uſually well blended together: all lines of ſeparation have, in a coarſe of time, been filled up; and therefore, when in made ground they are left open, that ground appears artificial.

Even where artifice is avowed, a breach in the connection offends the eye. The uſe of a foſſe is merely to provide a fence, without obſtructing the view. To blend the garden with the country is no part of the idea: the cattle, the objects, the culture, without the ſunk fence, are diſcordant to all within, and keep up the diviſion. A foſſe may open the moſt poliſhed lawn to a cornfield, a road, or a common, though they mark the very point of ſeparation. It may be made on purpoſe to ſhew objects which cannot, or ought not to be in the garden; as a church, or a mill, a neighbouring gentleman's ſeat, a town, or a village; and yet no conſciouſneſs of the exiſtence can reconcile us to the ſight of this diviſion.

If, where no union is intended, a line of ſeparation is diſagreeable, it muſt be diſguſting when it breaks the connection between the ſeveral parts of the ſame piece of ground. The manner of concealing the ſeparation ſhould itſelf be diſguiſed: and different degrees of cavity and rotundity; different ſhapes and dimenſions to the little parts thus diſtinguiſhed by degrees; and thoſe parts breaking, in one place more in another leſs, into the principal forms which are to be united; produce that variety with which all nature abounds, and without which ground cannot be natural.

Relation of the Parts to the Whole.

The relation of all the parts to the whole, when clearly marked, facilitates their junction with each other: for the common bond of union is then perceived, before there has been time to examine the ſubordinate connections; and if theſe ſhould be deficient in ſome niceties, the defect is loſt in the general impreſſion. But any part which is at variance with the reſt, is not rarely a blemiſh in itſelf: it ſpreads diſorder as far as its influence extends; and the confuſion is in proportion as the other parts are more or leſs adapted to point out any particular direction, or to mark any peculiar character in the ground. If, in ground all deſcending one way, a piece is twiſted another, the general fall is obſtructed by it; but if all the parts incline in the ſame direction, it is hardly credible how ſmall a declivity will ſeem to be conſiderable. An appearance even of ſteepneſs may be given to a very gentle deſcent, by raiſing hillocks upon it, which ſhall lean to the point, whither all the reſt are tending; for the eye meaſures from the top of the higheſt, to the bottom of the loweſt ground; and when the relation of the parts is well preſerved, ſuch an effect from one is transfuſed over the whole.

The general idea muſt however, be preſerved, clear even of a doubt. A hillock which only intercepts the ſight, if it does not contribute to the principal effect, is at the beſt an unneceſſery excreſcence; and even an interruption in the general tendency, though it hide nothing, is a blemiſh. On a deſcent, any hollow, any fall, which has not an outlet to lower ground, is a hole: the eye ſkips over it; inſtead of being continued along it; it is a gap in the compoſition.

As ſcenes increaſe in extent, they become more impatient of controul; they are not only leſs manageable, but ought to be leſs reſtrained; they require more variety and contraſt. But ſtill the ſame principles are applicable to the leaſt, and to the greateſt, though not with equal ſeverity; neither ought to be rent to pieces: and though a ſmall neglect, which would diſtract the one, may not diſturb the other, yet a total diſregard of all the principles of union is alike productive of confuſion in both.

Character of Ground.

The *ſtyle* alſo of every part, muſt be accommodated to the character of the whole. A large, deep, abrupt break, among eaſy ſwells and falls, ſeems at the beſt but a piece left unfiniſhed, and which ought to be ſoftened; it is not more natural, becauſe it is more rude; nature forms both the one and the other, but ſeldom mixes them together. On the other hand, a ſmall fine poliſhed, form, in the midſt of rough, miſhapen ground, though more elegant than all about it, is generally no better than a patch, itſelf diſgraced, and disfiguring the ſcene. A thouſand inſtances might be adduced to ſhew, that the prevailing idea ought to pervade every part, ſo far at leaſt indiſpenſably as to exclude whatever diſtracts it, and as much further as poſſible to accommodate the character of the ground to that of the ſcene it belongs to.

On the ſame principle, the *proportion* of the parts may often be adjuſted. For though their ſize muſt be very much governed by the extent of the place, and a feature which would fill up a ſmall ſpot may be loſt in a large one; though there are forms of a particular caſt, which appear to advantage only within certain dimenſions, and ought not therefore to be applied where they have not room enough, or where they muſt occupy more ſpace than becomes them; yet, independent of theſe conſiderations, a character of greatneſs belongs to ſome ſcenes, which is not meaſured by their extent, but raiſed by other properties, ſometimes only by the proportional largeneſs of their parts. On the contrary, where elegance characteriſes the ſpot, the parts ſhould not only be ſmall, but diverſified beſides with ſubordinate inequalities, and little delicate touches every where ſcattered about them. Striking effects, forcible impreſſions, whatever ſeems to require effort, diſturb the enjoyment of a ſcene intended to amuſe and to pleaſe.

Variety in Grounds.

Ground is ſeldom beautiful or natural without *variety*, or even without contraſt; and the precautions which have been given, extend no farther than to prevent variety from degenerating into inconſiſtency, and contraſt into contradiction. Within the extremes, nature ſupplies an inexhauſtible fund; and variety thus limited, ſo far from deſtroying, improves the general effect; Each diſtinguiſhed part makes a ſeparate impreſſion; and all bearing the ſame ſtamp, all concurring to the ſame end, every one is an additional ſupport to the prevailing idea; that is multiplied, it is extended, it appears in different ſhapes, it is ſhewn in ſeveral lights, and the variety illuſtrates the relation. But variety wants not this recommendation; it is always deſirable where it can be properly introduced: and an accurate obſerver will ſee in every *form* ſeveral circumſtances by which it is diſtinguiſhed from every other. If the ſcene be mild and quiet, he will place together thoſe which do not differ widely; and he will gradually depart from the ſimilitude. In ruder ſcenes, the ſucceſſion will be leſs regular, and the tranſitions more ſudden. The character of the place muſt determine the degree of difference between forms which are contiguous. Beſides diſtinctions in the ſhapes of ground, differences in their *ſituations* and their *dimenſions* are ſources of variety. Sometimes a very diſagreeable effect, produced by too cloſe a reſemblance of ſhapes, may be remedied only by an alteration in the ſize. If a ſteep deſcends in a ſucceſſion of abrupt falls, nearly equal, they have the appearance of ſteps, and are neither pleaſing nor wild; but if they are made to differ in height and length, the objection is removed; and at all times a difference in the dimenſions will be found to have a greater effect than in ſpeculation we ſhould be inclined to aſcribe to it, and will often diſguiſe a ſimilarity of figure.

Extraordinary Effects of Grounds.

The application of any of the foregoing obſervations to the ſtill greater ſcenes of nature, would carry us at preſent too far. Many of the above remarks are, however, ſo far of uſe in ſcenes the fartheſt from our reach, as they may aſſiſt in directing our choice of thoſe parts which are in our power to ſhew, or to conceal, though not to alter. But in converting them to this purpoſe, a caution, which has more than once been alluded to, muſt always be had in remembrance: never to ſuffer general conſiderations to interfere with ***extraordinary great effects***, which riſe ſuperior to all regulations, and perhaps owe part of their force to their deviation from them. Singularity cauſes at leaſt ſurpriſe, and ſurpriſe is allied to aſtoniſhment. Theſe effects are not, however, attached merely to objects of enormous ſize; they frequently are produced by a greatneſs of ſtyle and character, within ſuch an extent as ordinary labour may modify, and the compaſs of a garden include. The caution therefore may not be uſeleſs within theſe narrow bounds; but nature proceeds ſtill further, beyond the utmoſt verge to which art can follow; and, in ſcenes licentiouſly wild, not content with contraſt, forces even contradictions to unite. The groteſque diſcordant ſhapes which are often there confuſedly jumbled together, might ſufficiently juſtify the remark. But the caprice does not ſtop here; to mix with ſuch ſhapes a form perfectly regular, is ſtill more extravagant; and yet the effect is ſometimes ſo wonderful, that we cannot wiſh the extravagance corrected.

SECT. II. Wood.

Characteriſtic Differences in Trees and Shrubs.

In the above inſtances the ground is the principal conſideration; but previous to any enquiry into the greater effects of wood, when it is itſelf an object of examination of the *characteriſtic differences* of trees and ſhrubs is neceſſary. We do not mean botanical diſtinctions: we mean apparent, not eſſential varieties; and theſe muſt be obvious and conſiderable, to merit regard in the diſpoſition of the objects they diſtinguiſh. Trees and ſhrubs are of different *ſhapes, greens,* and *growths.* The varieties in their ſhapes may be reduced to the following heads. Some thick with branches and foliage have almoſt *an appearance of ſolidity*; as the beach and the elm, the lilac and ſyringa. Others thin of boughs and of leaves ſeem *light and airy*; as the aſh and the arbele, the common arbor vitæ and the tamariſk. There is a *mean betwixt the two extremes*, very diſtinguiſhable from both; as in the bladder-nut, and the aſhen-leaved maple. They may again be divided into thoſe whoſe *branches begin from the ground*, and thoſe which *ſhoot up in a ſtem before their branches begin.* Trees which have ſome not much clear ſtem, as ſeveral of the firs, belong to the former claſs; but a very ſhort ſtem will rank a ſhrub, ſuch as the althæa, in the latter. Of thoſe whoſe branches begin from the ground, ſome riſe in a *conical figure*, as the larch, the cedar of Lebanon, and the holly; ſome *ſwell out in the middle of their growth, and diminiſh at both ends*, as the Weymouth pine, the mountain aſh, and the lilac: and ſome are *irregular and buſhy* from the top to the bottom, as the evergreen oak, the Virginian cedar, and Guelder roſe. Theſe are the moſt obvious great diſtinctions in the ſhapes of trees and ſhrubs. The differences between ſhades of green cannot be ſo conſiderable; but theſe alſo will be found well deſerving of attention. Some are of a *dark green*, as the horſe-cheſnut and the yew; ſome of a *light green*, as the lime and the laurel; ſome of a *green tinged with brown*; as the Virginian cedar; ſome of a *green tinged with white*, as the arbele and the ſage-tree; and ſome of a *green tinged with yellow*, as the aſhen-leaved maple and the Chineſe arbor vitæ. The variegated plants alſo are generally entitled to be claſſed with the white, or the yellow, by the ſtrong tincture of the one or the other of thoſe colours on their leaves.

The preſent enquiry is only into great fixed diſtinctions. Thoſe in the ſhapes and the greens of trees and ſhrubs have been mentioned: there are others, as great and as important, in their growths; but they are too obvious to deſerve mentioning. Every gradation, from the moſt humble to the moſt lofty, has, in certain ſituations, particular effects; it is unneceſſary to divide them into ſtages.

Variety ariſing from thoſe Differences.

One principal uſe in ſettling theſe characteriſtic diſtinctions, is to point out the ſtores whence varieties may at all times be readily drawn, and the cauſes by which ſometimes inconſiſtencies may be accounted for. There are intermediate degrees, by which the moſt diſtant may be reconciled: the upright branches of the almond mix very ill with the falling boughs of the weeping willow; but an interval filled with other trees, in figure between the two extremes, renders them at leaſt not unſightly in the ſame plantation. Thoſe, on the contrary, which are of one character and are diſtinguiſhed only as the characteriſtic mark is ſtrongly or faintly impreſſed upon them, as a young beech and a birch, an acacia and a larch, all pendant, though in different degrees, form a beautiful maſs, in which unity is preſerved without ſameneſs; and ſtill finer groupes may often be produced by greater deviations from uniformity into contraſt. To range the ſhrubs and ſmall trees ſo that they mutually ſet off the beauties, and conceal the blemiſhes, of each other; to aim at no effects which depend on a nicety for their ſucceſs, and which the ſoil, the expoſure, or the ſeaſon of the day, may deſtroy; to attend more to the groupes than to the inviduals; and to conſider the whole as a plantation, not as a collection of plants; are the beſt general rules which can be given concerning them.

Mixture of Greens.

The different tints of greens may ſeem at firſt ſight to be rather minute varieties than characteriſtic diſtinctions: but upon experience it will be found, that from ſmall beginnings they lead to material conſequences; that they are more important on the broad expanſe, than along the narrow outline of a wood; and that by their union, or their contraſt, they produce effects not to be diſregarded in ſcenes of extent and of grandeur.

A hanging wood in autumn is enriched with colours, whoſe beauty cheers the approaches of the inclement ſeaſon they forebode; but when the trees firſt droop, while the verdure as yet only begins to fade, is the time to learn the ſpecies, the order, and the proportion of tints, which blended will form *beautiful maſſes*; and, on the other hand, to diſtinguiſh thoſe which are *incompatible*, near together. The peculiar beauty of the tints of red cannot then eſcape obſervation, and the want of them throughout the ſummer-months muſt be regretted; the red is aſſumed in ſucceſſion by the bud, the bloſſom, the berry, the bark, and the leaf. Sometimes it profuſely overſpreads, at other times it dimly tinges the plant; and a *reddiſh green* is generally the hue of thoſe plants, on which it laſts long, or frequently returns. Admitting this, at leaſt for many months in the year, among the characteriſtic diſtinctions, a large piece of red green, with a narrow edging of dark green along the the further ſide of it, and beyond that a piece of light green larger than the firſt, will be found to compoſe a beautiful maſs. Another, not leſs beautiful, is a yellow green neareſt to the eye, beyond that a light green, then a brown green, and laſtly a dark green. The dark green muſt be the largeſt, the light green the next in extent, and the yellow green the leaſt of all. From theſe combinations, the agreements between particular tints may be known. A light green may be next either to a yellow or a brown green, and a brown to a dark green, all in conſiderable quantities; and a little rim of dark green may border on a red or a light green. Further obſervations will ſhew, that the yellow, and the white greens, connect eaſily; but that a large quantity of the light, the yellow, or the white greens, does not mix well with a large quantity alſo of the dark green; and that to form a pleaſing maſs, either the dark green muſt be reduced to a mere edging, or a brown or an intermediate green muſt be interpoſed.

In maſſing theſe tints, an attention muſt be conſtantly kept up to their *forms*, that they do not lie in large ſtripes one beyond another; but that either they be quite intermingled, or, which is generally more pleaſing, that conſiderable pieces of different tints, each a beautiful figure, be, in different proportions, placed near together. Exactneſs in the ſhapes muſt not be attempted, for it cannot be preſerved; but if the great outlines be well drawn, little variations, afterwards occaſioned by the growth of the plants, will not ſpoil them. While the union of tints is productive of pleaſing effects, ſtrong effects may, on the other hand, be ſometimes produced by their *diſagreements*. Oppoſites, ſuch, for inſtance, as the dark and light greens, in large quantities cloſe together, break to pieces the ſurface upon which they meet; every oppoſition of tints is a break in a continued line; the depth of receſſes, may be deepened by darkening the greens as they retire; a tree which ſtands out from a plantation, may be ſeparated by its tint as much as by its poſition; the appearance of ſolidity or airineſs in plants depends not ſolely on the thickneſs or thinneſs, but partly on the colour of the leaves; clumps at a diſtance may be rendered more or leſs diſtinct by their greens; and the fine effect of a dark green tree, or groupe of trees, with nothing behind it but the ſplendor of a morning or the glow of an evening ſky, cannot be unknown to any who was ever delighted with a picture of Claude, or with the more beautiful originals in nature. Another effect attainable by the aid of the different tints, is founded on the firſt principles of *perſpective.* Objects grow faint as they retire from the eye; a detached clump, or a ſingle tree, of the lighter greens, will therefore, ſeem farther off than one equidiſtant of a darker hue; and a regular gradation from one tint to another will alter the apparent length of a continued plantation, according as the dark or light greens begin the gradation. Experiments will ſupport the principle, if they are made on plantations not very ſmall, nor too cloſe to the eye; the ſeveral parts may then be ſhortened or lengthened, and the variety of the outline be improved by a judicious arrangement of greens. Other effects ariſing from mixtures of greens will occaſionally preſent themſelves in the *diſpoſition* of a wood, which is the next conſideration.

Of the ſeveral Species of Wood.

Wood, as a general term, comprehends all trees and ſhrubs in whatever diſpoſition; but it is ſpecifically applied in a more limited ſenſe, and in that ſenſe we ſhall now uſe it. Every plantation muſt be either a *wood*, a *grove*, or a *clump.* A wood is compoſed both of trees and underwood; covering a conſiderable ſpace. A grove conſiſts of trees without underwood. A clump differs from either only in extent; it may be either cloſe or open; when cloſe, it is ſometimes called a *thicket*; when open, a *groupe of trees*; but both are equally clumps, whatever may be the ſhape or ſituation. One of the nobleſt objects in nature is the *ſurface of a large thick wood,* commanded from an eminence, or ſeen from below, hanging on the ſide of a hill. The latter is generally the more intereſting object. Its aſpiring ſituation gives it an air of greatneſs; its termination is commonly the horizon; and, indeed, if it is deprived of that ſplendid boundary, if the brow appears above it, (unleſs ſome very peculiar effect characteriſes that brow), it loſes much of its magnificence: ſingle trees in the midſt of a wood, though ſeldom of uſe to diverſify a ſurface, often deſerve particular regard as individuals, and are important to the greatneſs of the whole. A few large trees, not eminent above all about them, but diſtinguiſhed by ſome ſlight ſeparation, are noble objects in themſelves; become the ſituation; and ſerve as a meaſure to the reſt. On the ſame principle, trees which are thin of boughs and of leaves, thoſe whoſe branches tend upwards, or whoſe heads riſe in ſlender cones, have an appearance more of airineſs than of importance; and are blemiſhes in a wood, where greatneſs is the prevailing idea. Thoſe, on the contrary, whoſe branches hang directly down, have a breadth of head, which ſuits with ſuch a ſituation, though their own peculiar beauty be loſt in it. Theſe decorations are natural graces, which never derogate from greatneſs; and a number of ſhades playing on the ſurface, over a variety of thoſe beautiful forms into which it may be caſt, enliven that ſameneſs, which, while it prevails, reduces the merit of one of the nobleſt objects in nature to that of mere ſpace. To fill that ſpace with objects of beauty, to delight the eye after it his been ſtruck, to fix the attention where it has been caught, and to prolong aſtoniſhment into admiration, are purpoſes not unworthy of the greateſt deſigns; and, in the execution, productive of embelliſhments, which in ſtyle are not unequal to ſcenes of richneſs and magnificence.

The Surface of a Romantic Wood.

When, in a romantic ſituation, very broken ground is overſpread with wood, it may be proper on the ſurface of the wood, to mark the inequalities of the ground. *Rudeneſs*, not greatneſs, is the prevailing idea; and a choice directly the reverſe of that which is productive of unity, will produce it. Strong contraſts, even oppoſitions, may be eligible; the aim is rather to disjoint than to connect; a deep hollow may ſink into dark greens; an abrupt bank may be ſhewn by a riſing ſtage of aſpiring trees, a ſharp ridge by a narrow line of conical ſhapes; firs are of great uſe upon ſuch occaſions; their tint, their form, their ſingularity, recommend them. It is but a number of regularities put together in a diſorderly manner, and equally diſtant from the beautiful both of art and of nature. The true beauty of an outline conſiſts more in breaks than in ſweeps; rather in angles than in rounds; in variety, not in ſucceſſion. The parts muſt not be multiplied till they are too minute to be intereſting, and ſo numerous as to create confuſion. A few large parts ſhould be ſtrongly diſtinguiſhed into their forms, their directions, and their ſituations; each of theſe may afterwards be decorated with ſubordinate varieties.

Character of Groves.

The character of a grove is *beauty*. Fine trees are lovely objects: a grove is an aſſemblage of them; in which every individual retains much of its own peculiar elegance, and whatever it loſes is transferred to the ſuperior beauty of the whole. To a grove, therefore, which admits of endleſs variety in the diſpoſition of the trees, differences in their ſhapes and their greens are ſeldom very important, and ſometimes they are detrimental. But the ſurface and the outline are not the only circumſtances to be attended to. Though a grove be beautiful as an object, it is beſides delightful as a ſpot to walk or to ſit in; and the choice and the diſpoſition of the trees for effects within, are therefore a principal conſideration. A regular plantation gives no ſatisfaction, becauſe we know that the ſame number of trees might be more beautifully arranged: neither in wild nor in cultivated nature do we ever ſee trees equi-diſtant from each other: that regularity belongs to art alone. The diſtances, therefore, ſhould be ſtrikingly different: the trees ſhould gather into groupes, or ſtand in various irregular lines, and deſcribe ſeveral figures: the intervals between them ſhould be contraſted both in ſhape and in dimenſions: a large ſpace ſhould in ſome places be quite open; in others the trees ſhould be ſo cloſe together, as hardly to leave a paſſage between them; and in others as far apart as the connection will allow. In the forms and the varieties of theſe groupes, theſe lines, and theſe openings, principally conſiſts the interior beauty of a grove. If the planter has not the patience to wait till the trees arrive at their full growth, it is poſſible to ſecure both a preſent and future effect, by fixing firſt on a diſpoſition which will be beautiful when the trees are large, and then intermingling another which is agreeable while they are ſmall. Theſe occaſional trees are hereafter to be taken away; and muſt be removed in time, before they become prejudicial to the others.

Uſes and Situations of Clumps.

The occaſions on which independent clumps may be applied, are many. They are often deſirable as beautiful objects in themſelves; they are ſometimes neceſſary to break an extent of lawn, or a continued line, whether of ground or of plantation; but on all occaſions a jealouſy of art conſtantly attends them, which irregularity in their figure will not always alone remove. Though elevations ſhew them to advantage, yet a hillock evidently thrown up on purpoſe to be crowned with a clump, is artificial to a degree of diſguſt: ſome of the trees ſhould therefore be planted on the ſides, to take off that appearance. The ſame expedient may be applied to clumps placed on the brow of a hill, to interrupt its ſameneſs: they will have leſs oſtentation of deſign, if they are in part carried down either declivity. The objection already made to planting many along ſuch a brow, is on the ſame principle: a ſingle clump is leſs ſuſpected of art; if it be an open one, there can be no finer ſituation for it, than juſt at the point of an abrupt hill, or on a promontory into a lake or a river. It is in either a beautiful termination, diſtinct by its poſition, and enlivened by an expanſe of ſky or of water about and beyond it. Such advantages may balance little defects in its form: but they are loſt if other clumps are planted near it; art then intrudes, and the whole is diſpleaſing. The figure of the glade, of the lawn, or of the wood, are principally to be attended to: the fineſt clumps, if they do not fall eaſily into the great lines, are blemiſhes; their connections, their contraſts, are more important than their forms. A line of clumps, if the intervals be cloſed by others beyond them, has the appearance of a wood, or of a grove; and in one reſpect the ſemblance has an advantage over the reality. In different points of view, the relations between the clumps are changed, and a variety of forms is produced, which no continued wood or grove, however broken, can furniſh. Theſe forms cannot all be equally agreeable; and too anxious a ſolicitude to make them every where pleaſing, may, perhaps, prevent their being ever beautiful.

SECT. III. WATER.

In conſidering the ſubjects of gardening, ground and wood firſt preſent themſelves; water is the next; which, though not abſolutely neceſſary to a beautiful compoſition, yet occurs ſo often, and is ſo capital a feature, that it is always regretted when wanting; and no large place can be ſuppoſed, a little ſpot can hardly be imagined, in which it may not be agreeable. It accommodates itſelf to every ſituation; is the moſt intereſting object in a landſcape, and the happieſt circumſtance in a retired receſs; captivates the eye at a diſtance, invites approach, and is delightful when near: it refreſhes an open expoſure; it animates a ſhade; cheers the dreerineſs of a waſte, and enriches the moſt crowded view. In form, in ſtyle, and in extent, it may be made equal to the greateſt compoſitions, or adapted to the leaſt: it may ſpread in a calm expanſe to ſoothe the tranquility of a ſpaceful ſcene; or hurrying along a devious courſe, add ſplendor to a gay, and extravagance, to a romantic ſituation. So various are the characters which water can aſſume, that there is ſcarcely an idea in which it may not concur, or an impreſſion which it cannot enforce.

A gently murmuring rill, clear and ſhallow, juſt gurgling, juſt dimpling, impoſes ſilence, ſuits with ſolitude, and leads to meditation; a briſker current, which wantons in little eddies over a bright ſandy bottom, or babbles among pebbles, ſpreads cheerfulneſs all around: a greater rapidity, and more agitation, to a certain degree are animating; but in exceſs, inſtead of wakening, they alarm the ſenſes: the roar and the rage of a torrent, its force, its violence, its impetuoſity tend to inſpire terror.

A ſtraight line of conſiderable length may find a place in that variety; and it is ſometimes of ſingular uſe to prevent the ſemblance of a river in a channel formed between iſlands and the ſhore. But no figure perfectly regular ought ever to be admitted; it always ſeems artificial, unleſs its ſize abſolutely forbid the ſuppoſition. A ſemicircular river, though the ſhape be beautiful, is not natural, and any rectilinear figure is abſolutely diſguſtful; but if one line be curved, another may ſometimes be almoſt ſtraight, the contraſt is agreeable. A ſtraight piece of water has the appearance of a cut canal, unleſs great breadth, a bridge acroſs it, and ſtrong contraſts between the objects on the banks, diſguiſe the formality. A very ſmall curvature obliterates every idea of art and ſtagnation; and a greater is often miſchievous; for an acceſs of deviation from a ſtraight towards a circular line, ſhortens the view, weakens the idea of continuation, and though not chargeable with ſtiffneſs, yet approaches to regularity; whereas the line of beauty keeps at a diſtance from every figure which a rule can determine or a compaſs deſcribe.

Caſcades.

The roar of caſcade belongs only to larger ſtreams; but it may be produced by a rivulet to a conſiderable degree, and attempts to do more have generally been unſucceſsful. A vain ambition to imitate nature in her great extravagancies betrays the weakneſs of art. A noble river, throwing itſelf headlong down a precipice, is an object truly magnificent, but the height, not the breadth, is the wonder: when it falls no more than a few feet, the regularity prevails; and its extent only ſerves to expoſe the vanity of affecting the ſtyle of a cataract in an artificial caſcade. Several little falls in ſucceſſion are preferable to one great caſcade which in figure or in motion approaches to regularity. A great caſcade fills us with ſurpriſe: and the motion, the agitation, the rage, the froth, and the variety of the water, are finally the objects which engage the attention: for theſe a rivulet is ſufficient; and they may there be produced without that appearance of effort which raiſes a ſuſpicion of art.

Bridges.

To give to bridges their full effect, the connection between them and the river muſt be attended to: from the want of it, the ſingle wooden arch, now much in faſhion, ſeems to us generally miſplaced. Elevated without occaſion, ſo much above, it is totally detached from, the river: it is often ſeen ſtraddling in the air, without a glimpſe of the water to account for it: and the oſtentation of it as an ornamental object, diverts all that train of ideas which its uſe as a communication might ſuggeſt. The vaſtneſs of Walton bridge cannot without affectation be mimicked in a garden, where the magnificent idea of including the Thames under one arch is wanting, and where the ſtructure itſelf reduced to a narrow ſcale retains no pretenſions to greatneſs. Unleſs the ſituation make ſuch a height neceſſary, or the point of view be greatly above it, or wood or riſing ground inſtead of ſky behind it, fill up the vacancy of the arch, it ſeems an effort without a cauſe, forced and prepoſterous.

In wild and romantic ſcenes may be introduced a ruined ſtone-bridge, of which ſome arches may be ſtill ſtanding, and the loſs of thoſe which are fallen may be ſupplied by a few planks, with a rail, thrown over the vacancy. It is a pictureſque object; it ſuits the ſituation; and the antiquity of the paſſage, the care taken to keep it ſtill open though the original building is decayed, the apparent neceſſity which thence reſults for a communication, give it an impoſing air of reality. In every ſcene of magnificence; in ſome, where elegance chiefly prevails, a bridge with a colonnade, or other ornamental ſtructure upon it, is characteriſtically proper, and it has a peculiarity which recommends it to many ſituations.

SECT. IV. Rocks.

Mere rocks, unleſs they are peculiarly adapted to certain impreſſions, may ſurpriſe, but can hardly pleaſe: they are too far removed from common life, too barren, and unhoſpitable; rather deſolate than ſolitary, and more horrid than terrible. So auſtere a character cannot be long engaging, if its rigour be not ſoftened by circumſtances which may belong either to theſe or to more cultivated ſpots.

Deſcription of Middleton-Dale, near Chatſworth.

Middleton dale is a cleft between rocks, aſcending gradually from a romantic village, till it emerges, at about two miles diſtance, on the vaſt moor lands of the Peake. It is a diſmal entrance to a deſart: the hills above it are bare; the rocks are of a grey colour; their ſurfaces are rugged, and their ſhapes ſavage; frequently terminating in craggy points, ſometimes reſembling vaſt unwieldy bulwarks, or riſing in heavy buttreſſes one above another; and here and there a miſhappen maſs bulging out hangs lowering over its baſe. No traces of men are to be ſeen, except in a road which has no effect on ſuch a ſcene of deſolation, and in the lime-kilns conſtantly ſmoking on the ſide; but the labourers who occaſionally attend them live at a diſtance; there is not a hovel in the dale; and ſome ſcanty withering buſhes are all its vegetation: both theſe appearances make it probable, that Middleton-dale is a chaſm rent in the mountain by ſome convulſion of nature, beyond the memory of man, or perhaps before the iſland was peopled: the ſcene, though it does not prove the fact, yet juſtifies the ſuppoſition; and it gives credit to the tales of the country people, who, to aggravate its horrors, always point to a precipice, down which they ſay that a poor girl of the village threw herſelf head-long, in deſpair, at the neglect of the man whom ſhe loved; and ſhew a cavern, where a ſkeleton was once diſcovered, but of what wretch is unknown, his bones were the only memorial left of him. All the drearineſs however of the place, which accords ſo well with ſuch traditions, abates upon the junction of another valley, the ſides of which are ſtill of rock, but mixed and crowned with fine wood; and Middleton-dale becomes more mild by ſharing in its beauties: near this junction a clear ſtream iſſues from under the hill, and runs down the dale, receiving as it proceeds many rills and ſprings, all as tranſparent as itſelf. The principal rivulet is full of little water-falls: they are ſometimes continued in ſucceſſion along a reach of conſiderable length, which is whitened with froth all the way; at other times the brook wreathes in frequent windings, and drops down a ſtep at every turn; or ſlopes between tufts of graſs, in a briſk, though not a precipitant deſcent; when it is moſt quiet, a thouſand dimples ſtill mark its vivacity; it is every where active, ſometimes rapid, ſeldom ſilent, but never furious or noiſy: the firſt impreſſions which it makes are of ſprightlineſs and gaiety, very different from thoſe which belong to the ſcene all around; but by dwelling upon both, they are brought nearer together; and a melancholy thought occurs, that ſuch a ſtream ſhould be loſt in watering a waſte; the wilderneſs appears more forlorn which ſo much vivacity cannot enliven; as the idea of deſolation is heightened by reflecting that the

> Flower is born to bluſh unſeen,
> And waſte its ſweetneſs on the deſart air;

and that

> The nightingale attunes her notes,
> Where none are left to hear.

If ſuch a ſcene occurs within the precincts of a park or a garden, no expence ſhould be ſpared to meliorate the ſoil, wherever any ſoil can be found. Without ſome vegetation among the rocks, they are only an object of curioſity, or a ſubject of wonder: but verdure alone will give ſome relief to the drearineſs of the ſcene; and ſhrubs or buſhes, without trees, are a ſufficiency of wood: the thickets may alſo be extended by the creeping plants, ſuch as pyracantha, vines, and ivy, to wind up the ſides, or cluſter on the tops of the rocks; the licentious irregularity of wood and of rocks, and a fantaſtic conduct of the ſtreams, neither of which would be tolerated in the midſt of cultivation, become and improve romantic ſpots; even buildings, partly by their ſtyle, but ſtill more by their poſition, in ſtrange, difficult, or dangerous ſituations, diſtinguiſh and aggravate the native extravagancies of the ſcene.

In the choice and the application of theſe accompaniments, conſiſts all our power over rocks; they are themſelves too vaſt and too ſtubborn to ſubmit to our controul; but by the addition or removal of appendages, which we can command, parts may be ſhewn or concealed, and the characters with their impreſſions may be weakened or enforced: to adapt the accompaniments accordingly is the utmoſt ambition of art when rocks are the ſubject. Art may interpoſe to ſhew theſe large parts to the eye, and magnify them to the imagination, by taking away thickets which ſtretch quite acroſs the rocks, ſo as to diſguiſe their dimenſions; or by filling with wood the ſmall intervals between them, and thus, by concealing the want, preſerving the appearance of continuation. A thicket, on other occaſions, makes the rocks which riſe out of it ſeem larger than they are. If they ſtand upon a bank overſpread with ſhrubs, their beginning is at the leaſt uncertain; and the preſumption is, that they ſtart from the bottom.

Deſcription of Matlock Bath, in Derbyſhire.

Many of the circumſtances which have been mentioned concur at Matlock Bath, which is ſituated in a vale near three miles long, ſhut up at one end by a riſing moor, and at the other end by vaſt cliffs of rock: the entrance into it is hewn through one of them, and is indeed a noble rude portal to a ſcene of romantic magnificence. One ſide of the valley is a very high range of hill, rough with buſhes, and great blocks or ledges of ſtone. The other ſide is waſhed by the Derwent, and conſiſts chiefly of rocks; which, however, are often interrupted by ſteep declivities of green ſward, large thickets, and gentle deſcents of fine fields from the adjacent country. From ſome ſuch ſcene probably was conceived the wild imagination in ancient mythology of the giants piling Pelion upon Oſſa: in this, all is vaſt; height, breadth, ſolidity, boldneſs of idea, and unity of ſtyle, combine to form a character of greatneſs, conſiſtent throughout, not uniform, unmixed with any littleneſs, unallayed with any extravagance. The direction of the courſe of the river Derwent, is exactly ſuch as might be wiſhed; but it is a torrent, in which force and fury prevail: the caſcades in it are innumerable; before the water is recovered from one fall, it is hurried down another; and its agitation being thus increaſed by repeated ſhocks, it puſhes on with reſtleſs violence to the next, where it daſhes againſt fragments of rocks, or foams among heaps of ſtones which the ſtream has driven together. The colour all along is of a reddiſh brown; even the foam is tinged with a duſky hue: and where there are no caſcades, ſtill the declivity of the bed preſerves the rapidity, and a quantity of little breakers continue the turbulence of the current. Many of theſe circumſtances are certainly great: but a more temperate river, rolling its full tide along with ſtrength and activity, without rage; falling down one noble caſcade, inſtead of many; and if animated ſometimes by reſiſtance, yet not conſtantly ſtruggling with obſtructions; would have been more conſiſtent with the ſedate ſteady dignity of theſe noble piles of rock, whoſe brightneſs, together with the verdure of a vigorous and luxuriant, though humble vegetation, and ſome appearances of culture, give to the whole an air of cheerful ſerenity, which is diſturbed by the impetuoſity of the Derwent.

Rocks characteriſed by Terror.

This river would be better ſuited to a ſcene characteriſed by that terror, which the combination of greatneſs with force inſpires, and which is animating and intereſting, from the exertion and anxiety attending it. The terrors of a ſcene in nature are like thoſe of a dramatic repreſentation: they give an alarm; but the ſenſations are agreeable, ſo long as they are kept to ſuch as are allied only to terror, unmixed with any that are horrible and diſguſting. Art may therefore be uſed to heighten them, to diſplay the objects which are diſtinguiſhed by greatneſs, to improve the circumſtances which denote force, to mark thoſe which intimate danger, and to blend with all here and there a caſt of melancholy.

Rocks characteriſed by Fancy.

The different ſpecies of rocks often meet in the ſame place, and compoſe a noble ſcene, which is not diſtinguiſhed by any particular character: it is only when one eminently prevails, that it deſerves ſuch a preference as to exclude every other. Sometimes a ſpot, remarkable for nothing but its wildneſs, is highly romantic: and when this wildneſs riſes to fancy, when the moſt ſingular, the moſt oppoſite forms and combinations are thrown together, then a mixture alſo of ſeveral characters adds to the number of inſtances which there concur to diſplay the inexhauſtible variety of nature.

Deſcription of Dovedale, near Aſhbourne in Derbyſhire.

So much variety, ſo much fancy, are ſeldom found within the ſame extent as in Dovedale. It is about two miles in length, a deep, narrow, hollow valley: both the ſides are of rock; and the river Dove in its paſſage between them is perpetually changing its courſe, its motion and appearance. In one particular ſpot, the valley almoſt cloſing, leaves hardly a paſſage for the river, which pent up, and ſtruggling for a vent, rages and roars and foams, till it has extricated itſelf from the confinement. In other parts, the ſtream, though never languid, is often gentle; flows round a little deſart iſland, glides between bits of bulruſhes, diſperſes itſelf among tufts of graſs or of moſs, bubbles about a water-dock, or plays with the ſlender threads of aquatic plants which float upon the ſurface. The rocks all along the dale vary as often in their ſtructure, as the ſtream in its motion. In one place, an extended ſurface gradually diminiſhes by a broad baſe almoſt to an edge; in another, a heavy top hanging forwards, overſhadows all beneath: ſometimes many different ſhapes are confuſedly tumbled together; and ſometimes they are broken into ſlender ſharp pinnacles, which riſe upright, often two or three together, and often in more numerous cluſters. On this ſide of the dale, they are univerſally bare; on the other, they are intermixed with wood; and the vaſt height of both the ſides, with the narrowneſs of the interval between them, produces a further variety: the rocks never continue long in the ſame figure or ſituation, ſometimes they form the ſides of the valley, in precipices, in ſteeps, or in ſtages; ſometimes they ſeem to riſe in the bottom, and lean back againſt the hill; and ſometimes they ſtand out quite detached, heaving up in cumbrous piles, or ſtarting into conical ſhapes, like vaſt ſpars, an 100 feet high; ſome are firm and ſolid throughout, ſome are cracked, and ſome, ſplit and undermined, are wonderfully upheld by fragments apparently unequal to the weight they ſuſtain. The changes in their diſpoſition are infinite; every ſtep produces ſome new combination; they are continually croſſing, advancing, and retiring: the breadth of the valley is never the ſame 40 yards together: at the narrow paſs which has been mentioned, the rocks almoſt meet at the top, and the ſky is ſeen as through a chink between them: juſt by this gloomy abyſs, is a wider opening, more light, more verdure, more cheerfulneſs, than any where elſe in the dale. Nor are the forms and the ſituations of the rocks their only variety: many of them are perforated by large natural cavities, ſome of which open to the ſky, ſome terminate in dark receſſes, and through ſome are to be ſeen ſeveral more uncouth arches, and rude pillars, all detached, and retiring beyond each other, with the light ſhining in between them, till a rock far behind them cloſes the perſpective: the noiſe of the caſcades in the river echoes amongſt them; the water may often be heard at the ſame time gurgling near, and roaring at a diſtance; but no other ſounds diſturb the ſilence of the ſpot: the only trace of men is a blind path, but lightly and but ſeldom trodden, by thoſe whom curioſity leads to ſee the wonders they have been told of Dovedale. It ſeems, indeed, a fitter haunt for more ideal beings: the whole has the air of enchantment. The perpetual ſhifting of the ſcenes; the quick tranſitions, the total changes; then the forms all around, groteſque as chance can caſt, wild as nature can produce, and various as imagination can invent; the force which ſeems to have been exerted to place ſome of the rocks where they are now fixed immoveable, the magic by which others appear ſtill to be ſuſpended; the dark caverns, the illuminated receſſes, the fleeting ſhadows, and the gleams of light glancing on the ſides, or trembling on the ſtream; and the lonelineſs and the ſtillneſs of the place, all crowding together on the mind, almoſt realize the ideas which naturally preſent themſelves in this region of romance and of fancy.

ARTICLE II.

OF THOSE PROPERTIES IN THE OBJECTS OF NATURE, WHICH SHOULD DETERMINE THE CHOICE AND ARRANGEMENT OF THEM IN GARDENING.

SECT. I. OF ART.

The ſeveral conſtituent parts of the ſcenes of nature having now been conſidered, the next inquiry is into the particular principles and circumſtances which may affect them when they are applied to the ſubjects of gardening.

It has always been ſuppoſed, that *art* muſt then interfere: but art was carried to exceſs, when ground, wood, and water, were reduced to mathematical figure, and ſimilarity and order were preferred to freedom and variety. Theſe miſchiefs, however, were occaſioned, not by the uſe, but the perverſion of art; it excluded, inſtead of improving upon nature, and thereby deſtroyed the very end it was called in to promote. The truth is, that both propoſitions are erroneous: architecture requires ſymmetry; the objects of nature freedom; and the properties of the one cannot with juſtice be transferred to the other. But if, by the term, no more is meant than merely *deſign*, the diſpute is at an end: choice, arrangement, compoſition, improvement, and preſervation, are ſo many ſymptoms of art, which may occaſionally appear in ſeveral parts of a garden, but ought to be diſplayed without reſerve near the houſe: nothing there ſhould ſeem neglected; it is a ſcene of the moſt cultivated nature: it ought to be enriched, it ought to be adorned; and deſign may be avowed in the plan, and expence in the execution. Even regularity is not excluded: a capital ſtructure may extend its influence beyond its walls: but this power ſhould be exerciſed only over its immediate appendages. Works of ſculpture are not, like buildings, objects familiar in ſcenes of cultivated nature; but vaſes, ſtatues, and termini, are uſual appendages to a conſiderable edifice: as ſuch, they may attend the manſion, and treſpaſs a little upon the garden, provided they are not carried ſo far into it as to loſe their connection with the ſtructure.

Delightful Scene in a Picture.

The greateſt beauties of nature will often ſuggeſt the remembrance; for it is the buſineſs of a landſcape painter to ſelect them: and his choice is abſolutely unreſtrained; he is at liberty to exclude all objects which may hurt the compoſition; he has the power of combining thoſe which he admits in the moſt agreeable manner; he can even determine the ſeaſon of the year, and the hour of the day, to ſhew his landſcape in whatever light he prefers. The works therefore of a great maſter, are fine exhibitions of nature, and an excellent ſchool wherein to form a taſte for beauty: but ſtill their authority is not abſolute; they muſt be uſed only as ſtudies, not as models; for a picture and a ſcene in nature, though they agree in many, yet differ in ſome particulars, which muſt always be taken into conſideration, before we can decide upon the circumſtances which may be transferred from the one to the other. Painting, with all its powers, is ſtill more unequal to ſome ſubjects, and can give only *a faint, if any, repreſentation* of them: but a gardener is not therefore to reject them: he is not debarred from a view down the ſides of a hill, or a proſpect where the horizon is lower than the ſtation, becauſe he never ſaw them in a picture. Even when painting exactly imitates the appearances of nature, it is often weak in conveying the ideas which they excite, and on which much of their effect ſometimes depends.

Many more inſtances might be alledged to prove that the ſubjects for a painter and a gardener are not always the ſame. Some which are agreeable in the reality, loſe their effect in the imitation; and others, at the beſt, have leſs merit in a ſcene than in a picture. The term pictureſque is therefore applicable only to ſuch objects in nature, as, after allowing for the differences between the arts of painting and of gardening, are fit to be formed into groupes, or to enter into a compoſition where the ſeveral parts have a relation to each other, and in oppoſition to thoſe which may be ſpread abroad in detail, and have no merit but as individuals.

SECT. II. GENERAL SUBJECT.

Differences between a Farm, a Garden, a Park, and a Riding.

The ſcenes of nature are alſo affected by the general ſubject to which they are applied, whether that be a *farm*, a *garden*, a *park*, or a *riding*. Theſe may all indeed be parts of one place; they may border on each other; they may, to a degree, be intermixed: but each is ſtill a character of ſuch force, that, which-ever prevails, the propriety of all other characters, and of every ſpecies of beauty, muſt be tried by their conformity to this. And circumſtances neceſſary to one may be inconſiſtencies in the reſt: *elegance* is the peculiar excellence of a garden, *greatneſs* of a park, *ſimplicity* of a farm, and *pleaſantneſs* of a riding. Theſe diſtinguiſhing properties will alone exclude from the one, many objects which are very acceptable in the others; but theſe are not the only properties in which they eſſentially differ. A garden is intended to walk or to ſit in, which are circumſtances not conſidered in a riding; a park comprehends all the uſes of the other two; and theſe uſes determine the *proportional extent* of each. A large garden would be but a ſmall park; and the circumference of a conſiderable park but a ſhort riding. A farm is in ſome meaſure denominated from its ſize: if it greatly exceed the dimenſions of a garden, ſo that its bounds are beyond the reach of a walk, it becomes a riding.

Proſpects are agreeable to either of the four general ſubjects, but not equally neceſſary to all. In a garden, or in a farm, ſcenes within themſelves are often ſatisfactory; and, in their retired ſpots, an opening would be improper. A park is defective, if confined to its incloſure; a perpetual ſucceſſion of home-ſcenes, through ſo large an extent, wants variety; and fine proſpects are circumſtances of greatneſs; but they are not required in every part. By concealing, therefore, much of the proſpects, we deſtroy the amuſement of a riding. The view of the country ſhould not be hurt by the improvements of the road. In a garden, on the contrary, continuation of ſhade is very acceptable; and if the views be ſometimes interrupted, they may ſtill be caught from many points; we may enjoy them there whenever we pleaſe; and they would pall if conſtantly in ſight. The beſt ſituation for a houſe is not that which has the greateſt command; a cheerful look-out from the windows is all that the proprietor deſires. He is more ſenſible to the charms of the greater proſpects, if he ſees them only occaſionally, and they do not become inſipid by being familiar; for the ſame reaſon he does not wiſh for them in every part of his garden; and temporary concealments give them freſh ſpirit whenever they appear. But the views of a riding are not viſited ſo often, as thereby to loſe any of their effect. Plantations, therefore, in a country, ſhould be calculated rather for objects to look at, than for ſhades to paſs through. In a park, they may anſwer both purpoſes; but in a garden, they are commonly conſidered as places to walk or to ſit in.

A park is ſometimes not much hurt by being turned to account. The uſe of a riding is to lead from one beauty to another, and be a ſcene of pleaſure all the way; made avowedly for that purpoſe only, it admits more embelliſhment and diſtinction than an ordinary road through a farm. See the articles FARM, PARK, and RIDING.

Many gardens are nothing more than a *walk round a field*; that field is often raiſed to the character of a lawn; and ſometimes the incloſure is, in fact, a paddock. Whatever it be, the walk is certainly a garden; it is a ſpot ſet apart for pleaſure; it admits on the ſides a profuſion of ornament; it is fit for the reception of every elegance; and requires the niceſt preſervation; it is attended alſo with many advantages; may be made and kept without much expence; leads to a variety of points; and avails itſelf, in its progreſs, of the ſeveral circumſtances which belong to the incloſure it ſurrounds, whether they be the rural appurtenances of a farm, or thoſe more refined which diſtinguiſh a paddock. This ſpecies of garden, therefore, ſeems proper only for a place of a very moderate extent; if it be ſtretched out to a great length, and not mixed with other characters, its ſameneſs hurts that variety, which is its peculiar merit to diſcover. For a further account of this ſpecies of garden, ſee the article FARM ORNAMENTAL.

The ſides of a gravel walk muſt correſpond, and its courſe be in ſweeps gently bending all the way. It preſerves its form, though conducted through woods, or along glades, of the moſt licentious irregularity. But a graſs walk is under no reſtraint: the ſides of it may be perpetually broken, and the direction frequently changed: ſudden turns, however, are harſh; they check the idea of progreſs; they are rather diſappointments than varieties; and if they are ſimilar, they are in the worſt ſtyle of affectation. The line muſt be curved, but it ſhould not be wreathed: if it be truly ſerpentine, it is the moſt unnatural of any. It ought conſtantly to proceed; and wind only juſt ſo much, that the termination of the view may differ at every ſtep, and the end of the walk never appear; the thickets which confine it ſhould be diverſified with ſeveral mixtures of greens; no diſtinctions in the forms of the ſhrubs or the trees will be loſt, when there are opportunities to obſerve them ſo nearly; and combinations and contraſts without number may be made, which will be there truly ornamental. Minute beauties are proper in a ſpot precluded from great effects; and yet ſuch a walk, if it be broad, is by no means inſignificant; it may have an importance which will render it more than a mere communication. If the ſpace be divided into little ſlips, and made only a collection of walks, it forfeits all its advantages, loſes its character, and can have no other excellence than ſuch as it may derive from ſituation; whereas, by a more liberal diſpoſition, it may be made independent of whatever is external; and though proſpects are no where more delightful than from a point of view which is alſo a beautiful ſpot, yet if in ſuch a garden they ſhould be wanting, the elegant, pictureſque, and various ſcenes within itſelf, almoſt ſupply the deficiency.

SECT. III. SEASON.

Every ſcene and every object is in its higheſt beauty only at particular hours of the day; and every place is, by its ſituation or its character, peculiarly agreeable in certain months of the year. The *ſeaſons* thus become ſubjects of conſideration in gardening; and when ſeveral of thoſe circumſtances which diſtinguiſh a ſpot more at one time than another happen to concur, it will often be worth the while to add to their number, and to exclude ſuch as do not agree with them, for no other purpoſe than to ſtrengthen their effect at that particular time.

Occaſional Effects.

Different parts may thus be adapted to different ſeaſons, and each in its turn will be in perfection. But if the place will not allow of ſuch a ſucceſſion, ſtill *occaſional effects* may often be ſecured and improved, without prejudice to the ſcene when they are paſt, and without affectation while they continue. The temple of Concord and Victory at Stowe is one of the nobleſt objects that ever adorned a garden: but there is a moment when it appears in ſingular beauty. The ſetting ſun ſhines on the long colonnade which faces the weſt: all the lower parts of the building are darkened by the neighbouring wood; the pillars riſe at different heights out of the obſcurity. On the ſtatues which adorn the ſeveral points of the pediment, a deep ſhade is contraſted to ſplendor: the rays of the ſun linger on the ſide of the temple long after the front is overcaſt with the ſober hue of evening; and they tip the upper branches of the trees, or glow in the openings between them, while the ſhadows lengthen acroſs the Grecian valley. Such an occaſional effect, however tranſient, is ſo exquiſitely beautiful, that it would be unpardonable to neglect it. Others may be produced at ſeveral hours of the day; and the diſpoſition of the buildings, of the ground, the water, and the plantations, may often be accommodated to ſupport them. There are alſo occaſional effects in certain months, or only weeks, of the year, ariſing from ſome particular bloom, ſome occupation then carrying on, or other incident which may ſo far deſerve attention as to recommend a choice and arrangement of objects, which at that time will improve the compoſition, though at another they may have no extraordinary merit. The ſame conſiderations direct the choice alſo of their appendages; and in conſequence of a judicious aſſemblage and arrangement of ſuch as are proper for the purpoſe, the *ſpirit* of the morning, the *exceſs* of noon, or the *temperance* of evening, may be improved or corrected by the application of the ſcene to the ſeaſon.

In a *morning*, the freſhneſs of the air allays the force of the ſunbeams, and their brightneſs is free from glare: the moſt ſplendid objects do not offend the eye, nor ſuggeſt the idea of heat in its extreme; but they correſpond with the glitter of the dew which beſpangles all the produce of the earth, and with the cheerfulneſs diffuſed over the whole face of the creation. A variety of buildings may therefore be introduced to enliven the view; their colour may be the pureſt white, without danger of exceſs, though they face the eaſtern ſun; and thoſe which are in other aſpects ſhould be ſo contrived, that their turrets, their pinnacles, or other points, may catch glances of the rays, and contribute to illuminate the ſcene. The trees ought in general to be of the lighteſt greens, and ſo ſituated as not to darken much of the landſcape by the length of their ſhadows. Vivacity in the ſtreams, and tranſparency in a lake, are more important at this than at any other hour in the day: and an open expoſure is commonly the moſt delightful, both for the effect of particular objects, and the general character of the ſcene.

At *noon*, every expedient ſhould be uſed to correct the exceſs of the ſeaſon. Grottos, caves, and cells, agreeable circumſtances in a ſequeſtered receſs; and though the chill within be hardly ever tolerable, the eye catches only an idea of coolneſs from the ſight of them. Other buildings ought in general to be caſt into ſhade, that the glare of the reflection from them may be obſcured. The large expanſe of a lake is alſo too dazzling: but a broad river moving gently, and partially darkened with ſhadow, is very refreſhing; more ſo perhaps than a little rill, for the vivacity of the latter rather diſturbs the repoſe which generally prevails at midday. Every breeze then is ſtill; the reflection of an aſpen-leaf ſcarcely trembles on the water: the animals remit their ſearch of food, and man ceaſes from his labour: the ſteam of heat ſeems to oppreſs all the faculties of the mind, and all the active powers of the body; and any very lively motion diſcompoſes the languor in which we then delight to indulge. To hear, therefore, the murmurs of a brook purling underneath a thicket, or the echo of falling waters through a wood, is more agreeable than the ſight of a current; the idea conveyed by the ſound is free from any agitation: but if no other ſtream than a rill can be introduced, the refreſhment which attends the appearance of water muſt not be denied to the ſcene.

In the evening, all ſplendor fades: no buildings glare; no water dazzles. The calmneſs of a lake ſuits the quiet of the time: the light hovers there, and prolongs the duration of day. An open reach of a river has a ſimilar, though a fainter, effect: and a continued ſtream all expoſed, preſerves the laſt rays of the ſun along the whole length of its courſe, to beautify the landſcape: but a briſk current is not ſo conſiſtent as a lake with the tranquility of evening. And other objects ſhould in general conform to the temper of the time. Buildings of a duſky hue are moſt agreeable to it: but a very particular effect from a ſetting ſun will recommend thoſe of a brighter colour; and they may alſo be ſometimes uſed, among other means, to correct the uniformity of twilight. No contraſt of light and ſhade can then be produced: but if the plantations, which by their ſituation are the firſt to be obſcured, be of the darkeſt greens, if the buildings which have a weſtern aſpect be of a light colour, and if the management of the lawns and the water be adapted to the ſame purpoſe, a diverſity of tints will be preſerved long after the greater effects are faded.

Of the Seaſons of the Year.

The delights, however, of the morning and evening are confined to a few months of the year; at other times, two or three hours before, and as much after, noon, are all that are pleaſant; and even then the heat is ſeldom ſo extreme as to require relief from its exceſs. The diſtinctions, therefore, between the three parts of the day may in general be reckoned among the characteriſtics of ſummer. A degree of importance may be given even to the flowers of a border. By collecting into one ſpot ſuch plants as have at the ſame time their accidental colours, as conſiderable effects may be produced from the concurrence of many little cauſes. Thoſe which ariſe from bloom are the moſt ſtriking, and the moſt certain; and they abound chiefly in the

Spring.

Bloom is a characteriſtic of the ſeaſon; and a villa near town, which is deſigned principally for that time of the year, is not adapted to its uſe if this property be not amply provided for. In ſuch a place, therefore, ſhrubberies, with an intermixture of flowers, are peculiarly proper. In the ſummer months, a border between the thicket and the greenſward, breaks the connexion, and deſtroys the greater effect: it ought not to be then introduced, except to enliven ſmall ſpots, and as the beſt ſpecies of parterre. But in the ſpring, the thicket is hardly formed: its principal beauty is bloom; and flowers before or among the ſhrubs, are agreeable to the character of the ſeaſon. An orchard, which at other times, is unſightly, is then delightful; and if a farm joins to the garden, ſhould not be forgotten. But evergreens appear in general to great diſadvantage. Moſt of them have a ruſſet or a dark hue, which ſuffers by being contraſted to the lively verdure of the young ſhoots on the deciduous trees. That verdure is, however, ſo light, and ſo univerſal, that effects, from a mixture of greens, can ſeldom be produced; and thoſe which depend on a depth of ſhade will often be diſappointed. But buildings, views of water, and whatever tends to animate the ſcene, accord with the ſeaſon; which is full of youth and vigour, freſh and ſprightly, brightened by the verdure of the herbage and the woods, gay with bloſſoms and flowers, and enlivened by the ſongs of the birds in all their variety, from the rude joy of the ſky lark, to the delicacy of the nightingale.

Summer.

The plantations ſhould be calculated at leaſt as much for places of retreat, as for ornaments of the view; and a continuation of ſhade be preſerved, with very few and ſhort interruptions, through all the parts of the garden. Communications by gravel walks are of leſs conſequence: they do not ſuggeſt that idea of utility which attends them in winter or autumn; and their colour, which in ſpring is a lively contraſt to the verdure through which it winds, is in the intemperate blaze of a ſummer day glaring and painful. They ſhould, therefore, be concealed as much as poſſible; and the other conſiderations which belong to the noon-tide hour ſhould be particularly attended to, at the ſame time that the delights of the morning and the evening are alſo liberally provided for. But, excluſive of all ſuch incidental circumſtances, the ſcenes of nature in general appear at this ſeaſon to the greateſt advantage: though the bloom of the ſpring be faded, and the verdure of the herbage may be ſometimes affected by drought; yet the richneſs of the produce of the earth, and the luxuriance of the foliage in the woods; the ſenſations of refreſhment, added to the beauty of water; the ideas of enjoyment which accompany the ſight of every grove, of every building, and every delightful ſpot; the characters of rocks, heightened by their appendages, and unallayed by any diſconſolate reflections; the connexion of the ground with the plantations, the permanency of every teint, and the certainty of every effect; all concur in ſummer, to raiſe the ſeveral compoſitions to their higheſt ſtate of perfection.

Autumn.

But maturity is always immediately ſucceeded by decay: flowers bloom and fade; fruits ripen and rot; the graſs ſprings and withers; and the foliage of the woods ſhoots, thickens, and falls. In the latter months of *autumn*, all nature is on the decline; it is a comfortleſs ſeaſon: not a bloſſom is left on the ſhrubs or the trees; and the few flowers which ſtill remain in the borders, dripping with wet and ſickening even as they blow, ſeem hardly to ſurvive the leaves of the plant which are ſhrivelling beneath them. But the change of the leaf precedes the fall; and thence reſults a variety of colours, ſuperior to any which the ſpring or the ſummer can boaſt of. To ſhew and to improve that variety ſhould be principally attended to, in a place, ſuch as a ſporting ſeat, which is frequented only in autumn. It appears to advantage, whenever the ſurface of a wood can be commanded; and it may be produced to a conſiderable degree, even in a ſhrubbery, if the plants are ſo diſpoſed as to riſe in gradation one behind another. By obſerving the tints which the leaves aſſume when they change, the choice may be directed to the improvement of their variety; and by attending to the times when they fall, a ſucceſſion of theſe tranſitory beauties may be provided, from the earlieſt to the lateſt in the ſeaſon. Many ſhrubs and trees are at this time alſo covered with berries, which furniſh ſtill further varieties of colour; both evergreens and deciduous plants abound with them; and the verdure of the former is beſides a welcome ſubſtitute to that which is daily fading away. Open buildings, airy groves, views of water, and the other delights of ſummer, now loſe their charms; and more homely circumſtances of comfort and convenience are preferable to all their beauties.

A place which is the reſidence of a family all the year is very defective, if ſome portion of it be not ſet apart for the enjoyment of a fine day, for air, and exerciſe, in *winter*. To ſuch a ſpot ſhelter is abſolutely eſſential; and evergreens being the thickeſt covert, are therefore the beſt; their verdure alſo is then agreeable to the eye; and they may be arranged ſo as to produce beautiful mixtures of greens, with more certainty than deciduous trees, and with almoſt equal variety; they may be collected into a wood; and through that wood gravel-walks may be led, along openings of a conſiderable breadth, free from large trees which would intercept the rays of the ſun, and winding in ſuch a manner as to avoid any draft of wind, from whatever quarter it may blow. The few hours of cheerfulneſs and warmth which its beams afford are ſo valuable, as to juſtify the ſacrifice even of the principles of beauty to the enjoyment of them; and therefore no objections of ſameneſs or formality can prevail againſt the pleaſantneſs of a ſtraight walk, under a thick hedge or a ſouth wall. The eye may, however, be diverted from the ſkreen, by a border before it, where the aconite and the ſnowdrop, the crocus and hepatica, brought forward by the warmth of the ſituation, will be welcome harbingers of ſpring; and on the oppoſite ſide of the walk, little tufts of lauruſtines, and of variegated evergreens, may be planted. The ſpot thus enlivened by a variety of colours, and even a degree of bloom, may be ſtill further improved by a green-houſe. The entertainment which exotics afford peculiarly belongs to this part of the year; and if amongſt them be interſperſed ſome of our earlieſt flowers, they will there blow before their time, and anticipate the gaiety of the ſeaſon which is advancing. The walk may alſo lead to the ſtoves, where the climate and the plants are always the ſame. And the kitchen-garden ſhould not be far off; for that is never quite deſtitute of produce, and always an active ſcene; the appearance of buſineſs is alone engaging; and the occupations there are an earneſt of the happier ſeaſons to which they are preparative. By theſe expedients even the winter may be rendered cheerful in a place, where ſhelter is provided againſt all but the bittereſt inclemencies of the ſky, and agreeable objects and intereſting amuſements are contrived for every hour of tolerable weather.

Extent and Study of Gardening.

To conclude: Whatever contributes to render the ſcenes of nature delightful, is amongſt the ſubjects of gardening; and animate as well as inanimate objects, are circumſtances of beauty or character. Several of theſe have been occaſionally mentioned; others will readily occur; and nothing is unworthy of the attention of a gardener, which can tend to improve his compoſitions, whether by immediate effects, or by ſuggeſting a train of pleaſing ideas. The whole range of nature is open to him, from the parterre to the foreſt; and whatever is agreeable to the ſenſes or the imagination, he may appropriate to the ſpot he is to improve: it is a part of his buſineſs to collect into one place, the delights which are generally diſperſed through different ſpecies of country. But in this application, the genius of the place muſt always be particularly conſidered: to force it, is hazardous; and an attempt to contradict it, is always unſucceſsful. The beauties peculiar to one character, cannot be transferred to its oppoſite: even where the characters are the ſame, it is difficult to copy directly from the one into the other; and by endeavouring to produce a reſemblance of a ſcene which is juſtly admired, the proper advantages of the place are often neglected for an imitation much inferior to the original. The excellence of the latter probably depends on the happy application of the circumſtances to the ſubject; and the ſubjects of both are never exactly alike. The art of gardening, therefore, is not to be ſtudied in thoſe ſpots only where it has been exerciſed; though they are in this country very numerous, and very various. Yet all together they contain but a ſmall proportion of the beauties which nature exhibits: and unleſs the gardener has reſtored his mind with ideas from the infinite variety of the country at large, he will feel the want of that number which is neceſſary for choice; he will have none ready to apply to the ſubject immediately before him; and will be reduced to copy an imitation. But improved places are of ſingular uſe to direct the judgment in the choice, and the combinations of the beauties of nature: an extenſive knowledge of them is to be acquired in the country where they caſually occur; diſcernment of their excellencies, and a taſte for the diſpoſition of them, is to be formed in places where they have been ſelected, and arranged with deſign.

ARTICLE III.

MONTHLY KALENDAR OF ORNAMENTAL FLOWERS, SHRUBS, &C. WITH PARTICULAR DIRECTIONS FOR CULTIVATING AND PRESERVING THEM.

JANUARY.

Great care ſhould be taken to protect the choiceſt flowers at this unfavourable ſeaſon.

Auriculas. — The beſt auriculas in pots ſhould be well protected from exceſſive rains, ſnow, or ſharp froſts; all of which would injure them. The choiceſt varieties of theſe plants ſhould always be removed in their pots, about the end of October, or beginning of November, and placed in frames, or in a bed arched over with hoops, in a warm dry ſituation in the full ſun, where they can be occaſionally covered when the weather is unfavourable; but let the covers be conſtantly off when the weather is mild and dry.

Planting Ranunculuſes, Anemones, &c. — Plant ranunculuſes and anemones, in mild dry open weather, if you have any now out of the ground: theſe now planted will ſucceed thoſe which were put in the ground in October or November. For the particular method of preparing the beds, and planting the roots, ſee the work of *September* and *October*.

Planting Tulips. — Tulips, if you have any out of the ground, ſhould now be planted the firſt ſettled open weather, to blow late, and to ſucceed thoſe planted in laſt autumn. Let this work be done as ſoon as the weather will permit, for if theſe roots are kept much longer out of the ground, they will blow very poorly.

Planting Crocuſes. — Any ſorts of crocuſes may ſtill be planted for an early ſpring bloom, if dry mild weather; generally planting them along the edges of the flower borders next the walks, and in flower beds, &c. commonly within five or ſix inches of the edge; though thoſe deſigned for the borders appear to greater advantage when diſpoſed to ſmall patches, than in a continued row. Draw a ſmall circle with your finger, about four or five inches diameter; in the middle plant one root, and plant three or four round the edge of the circle: about twenty inches, or two or three feet farther, make another circle, and plant the roots as above; and ſo proceed to the end of the border, &c. obſerving, if you have different kinds, to plant each ſort ſeparate; that is, if you plant the firſt patch with yellow crocuſes, plant the next with blue, and ſo proceed with others of different ſorts.

Planting various Sorts of Bulbs. — Jonquils, narciſſuſes, hyacinths, bulbous iris, crown imperials, or any other kind of bulbous flower roots, that yet remain above ground, ſhould now be planted as ſoon as the weather will permit. Mild dry weather muſt be choſen to plant theſe, and all other kinds of bulbous roots, and ſee that the ground is not too wet. When it is intended to plant any of the common ſorts of the above, or other kinds of bulbous roots, in the borders, it will be the beſt way to plant them in little clumps or patches, in the manner mentioned above for the common tulips, ranunculuſes, &c.

Planting Flowering Shrubs. — In ſettled open weather, you may now plant, where wanted, moſt ſorts of hardy flowering ſhrubs. Such as roſes, honey ſuckles, lilacs, and ſyringas, althea and ſpiræa frutex, gelder-roſe, Perſian lilacs, laburnums, privets, and jaſmines, the cinquefoil ſhrub, and bladder-ſcna, the double hawthorn, double-bloſſom cherry, and dwarf almond, with double and ſingle flowers, the mezereon and double-flowering peach, with the double and ſingle ſweet-briar, flowering raſpberry, and double bramble; and many other ſuch like hardy kinds of ſhrubs may at this time be tranſplanted, provided the weather be any thing mild.

Tranſplant Suckers for Propagation. — Tranſplant ſuckers from the roots of roſes, lilacs, ſpiræas, ſyringas, and other ſhrubs, to raiſe a ſupply of new plants; for by ſuckers many ſorts of ſhrubs may be propagated: let theſe ſuckers be taken off carefully, with roots to each, and planted in rows eighteen inches aſunder; they will make good plants in two years time.

Propagating by Cuttings. — Cuttings of the young ſhoots of many ſorts of hardy deciduous ſhrubs, may alſo now be planted in open weather, eſpecially towards the latter end of the month, and they will ſucceed, take root in ſpring and ſummer, ſhoot at top, and form good rooted young plants by next autumn.

FEBRUARY.

Tender Annual Flowers. — About the middle, or towards the latter end of this month, it will be time to begin to prepare for ſowing ſome of the more curious ſorts of tender annuals. The choiceſt kinds are, the double balſams, cockſcombs, and tricolors, the globe amaranthus, marvel of Peru, diamond ficoides, or ice plant, egg plant, ſtramonium, browallia, &c. All theſe require the aſſiſtance of a hot-bed to bring them forward, in order that they may blow early, and in ſome tolerable perfection. When the plants appear, admit freſh air to them every day, when the weather is any thing mild; and let them have, now and then, little ſprinklings of water. Mind to cover the glaſſes every night with mats. But in raiſing the above annuals, if it is required to be ſaving of hot dung and trouble, and that if there are cucumber or melon hot beds at work, you may ſow them in pots, and place them in thoſe beds to raiſe the plants, which may be afterwards, tranſplanted in the ſame, or into a nurſery hot bed, to forward them to a proper ſize. See *April* and *May*. For the further management of theſe plants, and directions for ſowing a general ſupply of the ſame ſorts, together with ſeveral other tender annuals, ſee the work of the *Flower Garden*, in *March*.

Sow Ten-week Stocks and Mignonette. — The ten-week ſtock is a pretty annual; none make a more agreeable appearance in the borders or clumps, and it continues a long time in bloom; and the mignionette imparts a ſweet odour. It is now time, about the beginning, and towards the middle or latter end of this month, to ſow a little of the ſeed, to raiſe a few plants to blow early in the ſummer; and cover them with mats every night, and in bad weather. But if the above bed of natural earth could be covered with a frame and glaſs, or with hand-glaſſes, it would be a greater advantage to the plants. When the plants have been up about a month or ſix weeks, they ſhould be tranſplanted where they are to remain.

Hardy Annual Flower Seeds. — About the end of this month, if the weather be mild and dry, you may ſow many ſorts of hardy annual flower ſeeds in the borders, and other parts of the pleaſure garden. The ſorts proper to ſow at this time are lark ſpur and flos adonis, convolvulus, lupines, ſweet ſcented and Tangier peas, candy tuſt, dwarf-lychnis, Venus' looking glaſs, Lobel's catch fly, Venus' navel-wort, dwarf-poppy, nigella, annual ſun-flower, oriental mallow, lavatera, and hawk-weed, with many other ſorts. All the above ſeeds muſt be ſowed in the places where you intend the plants ſhall flower, in beds, borders, pots, &c. they muſt not be tranſplanted, for theſe ſorts will not ſucceed ſo well by that practice.

Blowing Annuals early in a Hot-houſe. — Any ſorts of deſireable annuals of moderate growth may be flowered early in a hot-houſe with little trouble, ſowing the ſeeds in pots and placing them in the bark-bed, &c.

Plant hardy fibrous-rooted Flowering Plants. — Now you may plant, where wanted, moſt ſorts of hardy fibrous-rooted flowering-plants both of perennials and biennials, ſuch as polyanthuſes, primroſes, London-pride, violets, double daiſies, double chamomile, thrift, gentianella, hepaticas, and ſaxifrage. Plant alſo roſe-campion, rockets, campanula, catch-fly, ſcarlet-lychnis, double feverfew, batchelor's-button, carnations, pinks, ſweet Williams, columbines, Canterbury-bells, monks-hood, Greek valerian, tree-primroſe, fox-glove, golden rods, perennial aſters, perennial ſun-flowers, holly-hocks, French honey-ſuckles, and many others. In planting the above, or any other ſorts, obſerve to diſpoſe them regularly, and intermix the different kinds in ſuch order as there may be a variety of colours, as well as a regular ſucceſſion of flowers in every part during the flowering ſeaſon.

Dreſs the Auricula Plants. — Now dreſs the auricula plants in pots, and add ſome freſh earth to them, provided it was not done the latter end of January. But this is now a more proper ſeaſon for performing this neceſſary work. The choiceſt kinds of auriculas in pots muſt now be treated with more than ordinary care, for their flower-buds will ſoon begin to appear; therefore the plants ſhould be defended from froſt and cold heavy rains; but every mild and dry day, the plants muſt be uncovered.

Sow Auricula and Polyanthus Seed. — Auricula and polyanthus ſeed may be ſown any time in this month; they will grow freely, and the plants from this ſowing will riſe well. Theſe ſeeds may be ſowed in a warm ſpot in the common ground, or in boxes or large pots filled with light rich earth; but the pots or boxes are often preferred, becauſe they can readily be removed to different ſituations, as the ſeaſon may require.

Tranſplant Carnation Plants. — Tranſplant the carnation plants in mild weather, which were raiſed laſt year from layers, into the large pots where you intend them to remain to blow, if not done in autumn; let this be done about the latter end of the month. When all is planted, ſet the plants in a ſituation well ſheltered from cold winds. Likewiſe plant carnations in the flower borders, in open weather, the middle or latter end of the month.

Tulips, Hyacinths, &c. — Defend the beds of the more curious or valuable tulips, hyacinths, anemones, and ranunculuſes, from froſt and exceſſive rains. This ſhould not now be omitted to the choiceſt kinds, when required to have them blow in their ultimate perfection; for although they are hardy enough, yet being protected this and next month from inclement weather, the blow will be much finer than if full expoſed; however, the more common kinds, either in beds or borders, may be permitted to take their chance.

Planting Flowering-Shrubs. — Moſt ſorts of flowering ſhrubs may now be ſafely removed any time in this month when it is open weather. But particularly the gelder roſe, ſyringas, laburnums, lilacs, honey-ſuckles, roſes, ſpiræas, and althæa-frutex, hypericum frutex, Perſian lilac, double-bloſſom cherry, double bramble, cornelian, cherry, and double hawthorn; you may likewiſe plant bladder-ſena, ſcorpion-ſena, privet, Spaniſh broom, jaſmines, ſumach, cityſuſes, and acacias, with many other ſorts of hardy deciduous ſhrubs, which may now be ſafely tranſplanted; for moſt ſorts will take root very freely and ſoon at this ſeaſon.

Planting Evergreens. — About the middle or any time in this month, if mild weather, you may tranſplant philyreas, alaternus, yews, evergreen-oaks, junipers, hollies, firs, cypreſs, cedars, laurels, lauruſtinus, pyracantha, arbutus, arbor-vitæ, ciſtuſes, with moſt other kinds of evergreens ſhrubs and trees.

Forcing early Flowers, &c. — Where early flowers are required, you may, in the beginning of this month, place various ſorts in pots, in hot-houſes, forcing-houſes, &c. now at work: and in hot-beds; ſuch as pots of pinks, carnations, ſweet-williams, anemones, ranunculuſes, narciſſus, early tulips, hyacinths, jonquils and any other ornamental and ſweet ſmelling ſpring flowers, both of the fibrous, bulbous, and tuberous rooted kinds, and they will blow early, and in good perfection. Likewiſe may have pots of roſes, and other deſireable flowering plants placed now in the hot-houſe, or any forcing department. About London the gardeners often force various flower plants for market, in boarded forcing frames, with the aſſiſtance of hot dung applied to the back part thereof; theſe frames being conſtructed of ſtrong inch and a half boards, made five, ſix, or ſeven feet high behind, the ends in proportion, and fronted with glaſs ſaſhes ſloping to the top of the back; may be four, five, or ſix, feet wide, at bottom, by one foot at top, the length at pleaſure; and in which placing pots of plants and ſhrubs, hot dung is piled againſt the back, and ends half a yard wide at bottom, and gradually narrowed to a foot width at top. The dung will throw in a fine heat, and the plants will flower agreeably at an early time; keeping up the heat when decreaſed by the application of freſh hot dung.

MARCH.

Sowing tender Annuals. — A hot bed may be made the beginning or any time of this month, to ſow the ſeeds of any kind of tender annual flowers in, ſuch as cockſcomb, amaranthus, tricolor, double balſamine, globe-amaranthus, ice plant, ſenſitive plant, &c. Remember they are not to remain in the hot-bed where raiſed, but are to be tranſplanted, ſome into pots, and ſome into the borders.

Sowing leſs tender Kinds of Annuals. — A ſlight hot-bed ſhould be made in the ſecond or third week of this month, wherein to ſow the ſeeds of the leſs-tender or hardier kinds of annual flowers. Such as the ſeeds of China aſter, India pink, marvel of Peru, balſam, palma Chriſti, capſicum mignonette, baſil, French and African marigolds, and ten-week ſtocks, chryſanthemum, tree and purple amaranthus, perſicarias, love-apple, ſcabiouſes, convolvulus major, ſtramoniums, and Chineſe hollyhocks, with ſeveral other ſorts. Obſerve, they are only to be raiſed in the hot-bed, and afterwards tranſplanted into the borders, &c. Or, for want either of a hot-bed or any of the other above mentioned conveniences, moſt of the ſeeds will ſucceed in a warm border next month, without any protection.

Hardy Annual Flowers. — Sow in the borders and other parts of the garden, the ſeeds of all ſorts of hardy annual flowers. The ſorts are large and dwarf annual ſun-flower, orential mallow, lavatera. Venice mallow, larkſpur, flos Adonis, ſweet ſultan, large fleſh-coloured and blue and yellow lupines. Sow alſo convolvulus major, ſweet-ſcented and Tangier peas, and naſturtiums. Likewiſe ſow the ſeeds of the Spaniſh nigella, purple and white candy-turf, Venus looking glaſs, Venus navel-wort, dwarf double poppy, Lobel's catchfly, dwarf annual lychnis, ſnails, caterpillars, convolvulus minor, and ſome others.

Auricula Plants. — If the auriculas in pots were not dreſſed laſt month, let it now be done early in this, as formerly directed. The fine auricula plants in pots ſhould now be guarded from too much wet, cold winds and froſt; ſuch weather being hurtful to their flower-buds, which are now in forwardneſs. The plants ſhould not be debarred from a warm and moderate ſhower of rain, which will now prove beneficial in promoting a free growth, and will ſtrenthen their advancing flower-buds. When the weather is dry, let them be refreſhed moderately with water at times, juſt enough to keep the earth a little moiſt about their roots.

Carnations. — The carnations which were raiſed from layers laſt year, and which are not yet planted into the large pots, borders, &c. where you intend them to flower, ſhould be planted therein the beginning of this month.

Planting Ranunculuſes and Anemones. — Finiſh planting all ranunculus and anemones; they will blow and make a fine appearance in May and June, after the early planted ones are gone. In dry weather, let the beds be frequently watered after the plants are up, and they will flower tolerably ſtrong.

Sowing various kinds of fibrous-rooted perennial and biennial Plants. Perennial and biennial flower-ſeeds, of moſt kinds, may be ſown towards the middle and latter end of the month. It is to be obſerved, that theſe kinds do not flower the ſame year they are ſown; but all the ſorts of them will flower ſtrong, and in the greateſt perfection the year after. As every one may not know the meaning of perennial and biennial plants, the perennial plants are theſe which continue many years, ſuch as everlaſting ſun-flower, perennial aſters, &c. The biennials are only of two years duration, being ſown one year, and flower and perfect their ſeeds the next, and ſoon after die: ſuch as the French honey-ſuckle, Canterbury bell-flower, &c. The kinds proper to be ſowed now, are carnations, pinks, ſweet-williams, wall-flowers, and ſtock July-flowers, of all ſorts. Sow alſo ſingle roſe-campion, catch-fly, ſcarlet lychnis, columbines, Greek valerian, ſcabiouſes, and Canterbury bells.

Tranſplanting Perennial Plants.—Where there are vacancies in any of the beds, borders, or other parts of the garden, they may now be filled up with many different kinds of flower plants, which will yet ſucceed, if planted ſoon in the month. The principal ſorts proper to plant now, are lychniſes, roſe-campions, rockets, catch-fly, campanulas, carnations, pinks, and ſweet-williams, wall-flowers, both double and ſingle; bachelors-buttons, and double fever-few; golden-rod, perennial ſun flowers, perennial aſters, and French honey-ſuckles; alſo columbines, Canterbury bells, monks-hood, fox-gloves, tree-primroſes, and moſt others of the like ſort. Plant alſo dwarf fibrous-rooted flowers, where wanted, in the borders; they will take root freely in a ſhort time. Such as polyanthuſes, auriculas, double daiſes, double chamomile, London pride, violets, hepaticus, thrift, primroſes, and gentianella; and any other of the like kinds, which ſucceed well, if planted any time this month. Give them ſome water when firſt planted, and at times till they are well rooted, and they will grow freely. Finiſh making plantations of all ſuch diciduous, ornamental, and foreſt-trees as are intended; moſt ſorts may ſtill be ſucceſsfully removed; but it is adviſeable to compleat it as ſoon as poſſible.

Planting Roſes.—Roſe-trees of moſt ſorts may ſtill be removed. Thoſe that are planted any time this month, will produce flowers the ſame year; but the ſooner they are planted the better they will take root, and the ſtronger they will flower. But by tranſplanting theſe ſhrubs late in the ſeaſon, you may obtain a late bloom. They may be planted in April and May, and they have flowered in July, Auguſt and September.

APRIL.

Tender Annual Flower Plants.—Make a new hot-bed, wherein to tranſplant the beſt kinds of early tender annuals, which were ſown in February, or any time in March. Such as cocks-combs, tricolors, double balſams, and globe aramanthus, egg plant, double ſtramonium, ſenſitive plant, and diamond ficoides, or ice plant. Where theſe curious plants are required in any tolerable degree of perfection, they muſt, at this time, be brought forward, by the aſſiſtance of a regular and due degree of hot-bed heat under frames and glaſſes; and where that is properly attended to, the plants will be large and beautiful by the end of June, or beginning of July. Remember to refreſh the plants often with moderate waterings, for it will greatly promote their growth.

Leſs tender Kinds of Annual Plants.—A ſlight hot-bed ſhould alſo be made now to prick ſome of the ſecond claſs or tender or hardier kinds of annual plants upon, which were raiſed laſt month. The principal ſorts are, marvel of Peru, China aſters, India pinks, ten-week ſtocks, mignonette, French and African marigolds, and chryſanthemums, likewſſe common balſams, baſil capſicums, and love apples, yellow ſweet ſultan, perſicaria, tree-amaranthus, purple amaranthus, prince's feather amaranthus, love-lies bleeding amaranthus, convolvulus major, ſcarlet convolvulus, palma-chriſti, ſcabious, alkekengi or winter-cherry, tobacco plant, zinnia, Indian corn, gourds in variety.

Hardy Annuals.—Hardy annual flower-ſeeds may yet be ſown in the borders, and other parts of this garden, in the places where they are to remain to flower, and in pots, &c. The ſorts which will yet ſucceed, are convolvulus major and minor; the Tangier and ſweet-ſcented peas, and the ſeeds of naſturtiums. Likewiſe lupines, larkſpur, flos Adonis, and common ſweet ſultans, poppy, hawk-weed, alſo Candy-tuft, dwarf lychnis, nigella or devil in a buſh, and Lobel's catchfly, Venus navel-wort and looking-glaſs, Virgin ſtock, ſnails, hedge-hogs, caterpillars, crown pea, winged pea, dwarf and large annual ſun-flower, perſicaria, belvidere, or ſummer cypreſs, lavateras, oriential mallow, blite, or ſtrawberry ſpinach, and other kinds of hardy annuals may ſtill be ſown.

Ten-week Stocks and Mignonette.—Sow ten-week ſtocks and mignonette, in any warm border, and rake them in, or ſow them thin in drills; they will readily grow; and be fit for tranſplantation in May and June.

Sowing Polyanthus.—Polyanthus ſeed may ſtill be ſown, and it will readily grow. But it muſt be ſown in the firſt or ſecond week in the month, otherwiſe the plants will not get ſtrength enough to flower next year. Such polyanthuſes as were raiſed laſt year from ſeed will many of them be now in bloom, and ſhould be carefully looked over, and the beſt flowers ſhould be marked, in order to their being tranſplanted to a place by themſelves.

Sowing Perennials and Biennials.—Sow ſuch perennial and biennial flower-ſeeds as are intended to be ſown this ſeaſon. The ſorts proper to ſow now, are wall-flowers, ſtock July flowers, ſweet williams, columbines, campanula, tree-primroſe, and Greek valerian; likewiſe the hollyhocks, and French honey-ſuckles, with the ſingle catch fly, roſe campion, ſcarlet lychnis, and the ſeeds of moſt other ſorts of hardy fibrous-rooted perennials and biennials.

Propagating Auriculas by Slips.—Auriculas are alſo increaſed by the off-ſets or ſuckers which riſe from the roots and ſides of the old plants; and this is a proper time to ſlip them off and plant them. They will now readily take root, and as the plants are now in bloom, you have the opportunity of ſeeing the flowers, and taking the ſlips from the plants of thoſe you like beſt, obſerving to ſlip them off cloſe with as much root as poſſible. The propagating theſe plants by ſlips is the only method to increaſe the ſorts you like; for the ſlips or ſuckers, will produce exactly the ſame kind of flowers as thoſe of the plants from whence they were taken; which is not ſo with the ſeedling plants; for the principal intention of floriſts, by raiſing them from ſeed, is to procure new ſorts; for there are always new varieties obtained from ſeed; and, perhaps, out of ſome hundreds ſo raiſed, not one prove exactly like the original from whence the ſeeds were ſaved.

Balm of Gilead.—This is the time to ſow ſeeds of balm of Gilead; theſe plants are of the perennial kind, and the ſtems and leaves remain all the year if protected in winter; are much eſteemed for the agreeable ſcent of their leaves, and make very proper furniture for the beds and borders of this garden, in ſummer; their ſtems riſing two or three feet high, they make a handſome appearance. The ſeed may be ſown either on a hot bed, or in a bed or border of natural earth, in a warm ſituation; but it will be moſt adviſeable to ſow them on a moderate hot bed, as the plants raiſed by this method will be brought greatly forward in the ſpring. The balm of Gilead may likewiſe be propagated by cuttings of the ſtalks, and that where they have been plants preſerved in frame, or in green houſes, all winter.

Planting Evergreens. Evergreen ſhrubs and trees of many ſorts, may yet be planted. But this ſhould be done in the firſt or ſecond week in the month. The ſorts which will yet bear removal, are hollies, bays, and yews; laurel, Portugal laurel, and lauriſtinus; phillyreas, alaternuſes, and pyracantha: cyſtiſuſes, and ciuſes, of all ſorts; alſo the arbutus, or ſtrawberry-tree; evergreen caſſine and magnolias; likewiſe pines, firs, cyprus, and junipers of all ſorts, cedars, &c.

Flowering Shrubs.—Where flowering ſhrubs are much wanted, they may yet be removed; but this muſt be done in the firſt or ſecond week of the month, or as ſoon as poſſible. The althea frutex, and Perſian lilac, will yet bear tranſplanting tolerably well: alſo the bladder and ſcorpion ſenas; honey ſuckles and jaſmines; ſyringas and laburnums; and moſt other hardy ſhrubs and trees.

MAY.

Continue to defend the beds of the more curious and capital kinds of hyacinths, and tulips now in flower, from the full ſun, heavy rains, cold nights, and all inclement weather; and alſo the choice kinds of ranunculuſes and anemones, which are now in bloom. Where this ſhading and ſheltering theſe kinds of flowers is duly practiſed, it will preſerve them a long time in their fulleſt beauty, at leaſt a fortnight or three weeks longer than if they were to be fully expoſed; and they will alſo be much finer.

Hyacinths paſt Flowering.—When hyacinths are paſt flowering, and the leaves juſt beginning to decay, let the roots then be taken up; but in particular the fine double kinds. As ſoon as they are taken up they ſhould be ſpread to dry and harden properly for keeping without danger of rotting.

Tulips done Blowing.—When tulips are paſt flowering, let the ſeed pod be immediately ſeparated from the top of the flower ſtalk; for the fine kinds of tulips ſhould never be permitted to ripen ſeeds, for theſe would draw nouriſhment and exhauſt the root. When the leaves and ſtalks of tulips begin to wither and decay, the roots ſhould then be taken up.

Bulbous Flowers in general done Blowing.—Spring crocus roots of all ſorts, and ſnow drops, and all other bulbous flower roots as have done blowing, ſhould be taken up when their leaves decay. When the roots are taken up, all the ſmall roots or off-ſets, are to be immediately ſeparated from the principal ones, and reſerve only the largeſt roots by themſelves, to plant again in the proper places, to blow next year, and by the off-ſets you obtain a conſiderable encreaſe. The roots when taken up muſt be properly dried in the ſhade, and afterwards put up till planting time, which is September, October, and November, or any time in open weather till February.

Autumn Flowering Bulbs.—The leaves of ſuch bulbs as blow in autumn, will, about the latter end of this month, be decayed; which, when it is intended to take up or tranſplant any of the ſorts, is the only proper time to remove them, and which may be done any time from about the end of May to the ſame time in June, as the roots then do not grow or draw nouriſhment from the ground. It is neceſſary that theſe bulbs, be taken up every two or three years at leaſt, to ſeparate the increaſed off-ſets from the main bulbs; and by theſe off-ſets you gain an increaſe of roots, ſome of which will flower the following autumn, and moſt of them the next year; and by diveſting the main root of the off-ſets, it will conſequently flower much ſtronger. They may then be put up till the laſt week in July, or the firſt week in Auguſt; when they are to be planted again for flowering the ſame year, in Auguſt and September, &c.

Carnations.—Carnation-plants in pots ſhould, at this time, have all the aſſiſtance of art, to encourage them to ſhoot with vigour.

Obſerve, that in order to have large and handſome flowers, all buds which riſe from the ſides of the ſtalks below, ſhould now be taken off, leaving none but the top buds; this is the method practiſed by floriſts. The pots ſhould now be placed where the midday ſun does not come; and in dry weather they muſt be watered once in two days.

Management of tender Annuals.—The cocks-combs, tricolors, balſams, globes, egg-plants, and other curious annuals, muſt now be removed, once more, into another new hot bed. Be ſure to admit air every day to the plants; and particularly when there is a good heat, and when there is much ſteam; for if this is not obſerved, the ſteam will deſtroy the leaves of the plants, and would, in that caſe, ſhake an aukward and unſightly appearance.

Prick out tender Annuals which were ſown laſt Month.—Where any of the above tender annual plants, ſuch as combs, tricolors, &c. were ſown laſt month, they ſhould now be pricked out. They muſt be pricked out on a hot bed, obſerving the method directed in the former months.

Leſs tender Annual Flower Plants.—Plant out the leſs tender or hardier annuals into the natural ground; this may be done any time after the middle of the month, if the weather is ſettled tolerably warm, taking advantage of a moiſt ſeaſon, if rain happens. The African and French marigold, and chryſanthemums, are of theſe kinds; alſo the marvel of Peru, China-aſter, India pink, ten week ſtocks, and the common kinds of balſams, capſicums, and mignonette; likewiſe perſicaria, and the tree and purple amaranthuſes; ſcabiouſes, egg-plant, love apples, and Chineſe hollyhocks, &c. All theſe may now be planted out in the beds, borders, and other parts of the garden, and they will make an agreeable appearance in two months time.

Sowing Hardier Annuals.—The ſeed of ten week ſtocks, mignonette, China-aſter, and Indian pink may ſtill be ſown. You may alſo, where omitted in the two laſt months, ſtill ſow the ſeeds of African and French marigold, balſams, chryſanthemums, and any other annuals of this claſs; but this ſhould be done the firſt or ſecond week in the month. Theſe ſeeds may now be ſown in natural ground.

Sow Seeds of hardy Annuals.—Sow the ſeed of hardy annual flowers in the borders; there are ſeveral ſorts that will ſtill ſucceed. Theſe are lupines, ſweet ſultan, and flos Adonis, the white and purple candy-tuft; Lobel's catchfly, and dwarf lychnis; dwarf poppy, and Virgin ſtock; Venus navel-wort, and Venus looking glaſs; ſnails and catterpillars; the ſeeds of dwarf and large annual ſun-flower; lavatera and oriental mallow, may alſo be ſown now; likewiſe naſturtiums, and convolvulus major and minor, the Tangier and ſweet-ſcented peas, and any other of the tribe of hardy annuals.

Auriculus.—Take good care of the auricula plants in pots, when they are paſt flowering. Off-ſets of auriculas may be now detached and planted in a ſhady border till autumn, then tranſplanted in pots, &c. Remove the boxes, or tubs of ſeedling auriculas and polyanthuſes, to a ſhady place, provided it was not done before: the place muſt be open to the morning ſun only.

Double Wall Flowers.—Propagate double wall flowers, by ſlips of the young ſhoots of the head; the plants raiſed by this method will retain the double property and colour of the flowers, in all reſpects the ſame as the parent plant, from which they were ſlipped. The wall flowers which were raiſed laſt year from ſeed, will now be in flower, not one plant in ten, or perhaps twenty or thirty, or thereabouts, will come double: and at other times not one in a hundred, and ſometimes in five hundred, or more, will prove multiple. Therefore where double flowers of a deep blood colour offer among the ſeedling plants, now is the time to propagate that ſort, by ſlips, as before directed.

Sow Biennial and Perennial and Flower Seeds.—Many ſorts of perennial and biennial flower-ſeeds may yet be ſown; but this ſhould be done in the firſt or ſecond week in the month, and the plants will come up ſtrong, and attain a proper growth, to produce flowers abundantly the next ſummer. The ſorts which will ſtill ſucceed, are the different ſorts of ſtock July flowers, wall-flowers, ſweet-williams, and columbines, carnations and pinks, and the ſeeds of ſcabiouſes; Canterbury or pyramidal bell flowers may alſo be ſown now; likewiſes hollyhocks, and French honey-ſuckles, and ſome other ſorts.

JUNE.

Tranſplanting Annuals.—Now plant out all the hardier kinds of annual flowers, into the different parts of the garden where they are to remain. The ſorts proper to plant out now, are French and African marigolds, chryſanthemums, perſicaria, the tree and purple amaranthuſes, and ſcabiouſes; the egg plant, ſtramonium, palma Chriſti, love-apple, and the tobacco plant. Plant out alſo the marvel of Peru; balſams, and capſicums; the China aſters, Indian pinks, Chineſe holly-hocks, mignonette, and ten-week ſtocks, with the large convolvulus, and ſuch like ſorts; but the laſt generally ſucceeds beſt when ſown where it is to remain.

Tender Annuals.—The cocks-combs and tricolors, globes, double balſams, double ſtramoniums, and egg-plant, and ſuch other curious annuals as were, in order to draw them up tall, placed in drawing-frames, or glaſs-caſes, will now need to be often refreſhed with water. The balſams that are in flower, and grown to any tolerable ſize, and alſo the combs and tricolors, and ſuch like, as are pretty ſtrong, may be brought into the open air, in the laſt week in this month; but if not arrived by that time to a proper ſize required, let them remain a week or two longer.

Hardy Annuals.—If any of the patches of hardy annuals in the borders remain too thick, let them now be thinned in the order directed laſt month, and give water. May ſtill ſow ſome quick flowering annuals to blow in autumn, ſuch as ten-week ſtocks, candytuft, virgin-ſtock, mignonette.

Tulips, Crown Imperials, Jonquils, &c.—Tulips will be now, in general, paſt flowering, and their leaves will be decayed; it is then proper time to take up the roots where intended, and to ſeparate the off-ſets. When they are thoroughly dried, put up each ſort ſeparately, in bag, or boxes, till September, October, or November; at which time plant them again.

Guernſey Lily Roots.—Tranſplant Guernſey and Belladona lily-roots; the leaves will now be decayed, which is the proper time to remove them. But theſe need not be taken up oftener than once in two or three years, eſpecially the Guernſey lily, which is then moſt neceſſary to be done, to ſeparate them from the increaſed parts, or off-ſets. The off-ſets ſhould alſo be planted in a bed, or pots, or boxes by themſelves, and will be ſtrong enough to flower in two or three years.

Ranunculus and Anemone Roots.—The ranunculus and anemone roots, that are paſt flowering, ſhould alſo, as ſoon as their leaves begin to wither, be taken out of the ground. When properly dried and cleaned, put them up in boxes, and place them in a dry room, till the time for planting them again in autumn and ſpring.

Management of Antumnal Flowering Bulbs.—The beginning or middle of this month you may ſtill take up, or tranſplant, moſt kinds of bulbous roots as blow in autumn. In particular, colchicums, autumnal-crocuſes, and narciſſus, and ſuch other autumnal flowering bulbs, or tuberoſe roots, whoſe leaves are decayed, and the roots not in a growing ſtate. When the roots are taken up, let all the off-ſets be taken away; the roots may then be planted again directly, or may be kept out of the ground ſome time; but not longer than the end of July, or till the firſt or ſecond week in Auguſt; becauſe, if kept longer out the ground, they will not blow with any tolerable degree of ſtrength in autumn.

Tranſplanting Seedling Perennials and Biennials.—Tranſplant from the ſeed-beds the wall-flowers, ſtock July flowers, ſweet williams, aud columbines, &c. which were ſown in March or April. Tranſplant alſo the hollyhocks, tree-primroſe, fox-gloves and pyramidal campanulas, Canterbury bells, and Greek valerian; ſingle roſe-campion, rockets, ſcarlet lychnis, and ſuch other perennial and biennial plants as were ſown two or three months ago. They will all flower next ſummer, and will make a beautiful appearance, provided they are properly placed in different parts of the garden.

Care of Blowing Carnations.—Take care of the choice ſtage carnations; ſome of the forwardeſt will probably, towards the latter end of the month, begin to break their flower pods for flowering, at which time ſuch as are required to blow in the utmoſt perfection, muſt be well attended. One great article in the beauty of this curious flower, is to have it open regularly; but this the larger flowers will not always do, without the help of an ingenious hand, and therefore in the capital varieties of theſe or other choice carnations, that in order to favour the equal opening of the flower pod, and more regular expanſion of the petals, which diſcover a tendency to burſt open irregularly, you may carefully ſlit the pod or cut the flower a little way down at the top, on the oppoſite ſide, in two or three different parts, ſo as to promote the flower ſpreading regularly each way round. Remember that the capital carnation plants in pots, which you deſign for ſtage flowers, ſhould, if not done in May, be now placed upon the ſtage; but the top of the ſtage muſt not be covered until the flowers are open, and then the cover muſt be conſtantly kept on, to defend them from the fiercer ſun, and from heavy rains; and keep the earth always moderately moiſt.

Planting Carnations and Pink Seedlings.—The carnation plants and pinks, raiſed this year from ſeed, will be ready, by the middle of the month, to be removed from the ſeed-bed into the nurſery-bed. In ten or twelve weeks time, they ſhould be removed into the borders among other plants.

Laying Carnation.—Propagate carnations by layers. This work is generally begun about the middle of this month and continued, according as the plants are fit, till the end of the next; the proper parts for laying, are principally the young ſhoots of the ſame year, when about five or ſix inches long. After you have planted them, in ſix weeks time, the layers will be finely rooted, and are then to be taken off from the old roots and planted, ſome of the beſt into ſmall pots, and the reſt into nurſery-beds, there to remain till October; at which time part may be taken up with balls of earth about their roots, and planted in the flower-borders.

Propagating Pinks and Carnations, by Pipings or Cuttings.—Propagate alſo pinks and carnations, by cuttings or pipings of the young ſhoots which is a neat and expeditious method of propagation, and is more peculiarly adapted for pinks; by which they may be very quickly raiſed in great abundance, as is the practice of the London gardeners, who raiſe great quantities annually of all the capital ſorts for market. The operation is commonly called piping, and is performed as follows. About the middle or latter of this, or beginning of next month the plants will have made proper ſhoots for this operation; however, any time between the the middle of June and the end of July, the cuttings may be taken off, obſerving you are to take only the upper, young, tender part of each ſhoot; and if the piping, or cutting hath, when taken off, two or three joints, it is ſufficient; either take them off with a knife, cutting them cloſe below a joint; otherwiſe take them off with the hand only; the method is this: take the head of the ſhoot between the ends of your fingers and thumb of one hand, and with the other hold the lower part of the ſhoot; then pulling the head of the ſhoot gently, it will readily part and come out of its pocket, about the third joint from the top; hence it is called piping. Or you may detach them more expeditiouſly with a knife, cutting them off about the third joint.

Double ſweet-williams and Pinks. — Double ſweet-williams and pinks may alſo be encreaſed by laying down the young ſhoots. The ſhoots of thoſe plants will be ready for laying towards the latter end of the month; and are to be prepared and layed in the ſame manner as the carnations. The layers of carnations, pinks, double ſweet-williams, and the like, raiſed this year, will all blow next ſummer.

Support Flowering Plants. — Continue to ſupport with ſticks all the tall growing plants, according as they grow up and require it. This work ſhould be duly attended to, for there is none more neceſſary, and nothing looks better than to ſee all the plants ſtanding firmly in their places, and neatly trained in an upright growth. Likewiſe to climbing plants, give proper ſupport of ſticks, &c. for they will now require that aſſiſtance.

JULY.

Cockſcombs, Tricolors, and other curious Annual Plants.—Bring out now the cockſcombs, tricolors, double balſams, and all other curious annuals as have been kept till this time in drawing frames, or in glaſs-caſes. When they are brought out, let them be immediately well cleared from all decayed leaves; and at the ſame time ſtir the earth a little in the top of the pots, and then add a ſprinkling of ſifted earth over it. They muſt, in dry weather, be very duly ſupplied with water: and this muſt be practiſed in general to all ſuch annuals as are planted in pots.

Tranſplant Annuals into the Borders, &c.—Where there are any kinds of tranſplanting-annual plants ſtill remaining in the ſeed bed, or in the nurſery bed, wherein they were prickled from the ſeed-bed, they ſhould in the beginning of the month be taken up with balls, or at leaſt with as much earth as you can about their roots, and planted in the borders or places allotted for them to blow.

Senſitive Plants.—The ſenſitive plants, if you raiſed any, ſhould now be again plunged in a moderate heat, or kept under glaſſes, to forward them, except you have the conveniency of a hot houſe, where you may keep them conſtantly. But thoſe who have no ſuch conveniency, ſhould, as above, place the pots containing them continually under glaſſes, either in a green houſe, glaſs caſe, or garden frame; but in winter they muſt be kept conſtantly in a hot houſe, or on any hot bed where a conſtant good heat is kept up. Thoſe plants are ſingularly curious on account of their leaves, which on the leaſt touch immediately drop, and quickly contract themſelves, and do not riſe and recover again in leſs than an hour.

Tranſplant Carnation Layers.—Take off and tranſplant ſuch carnation layers as were layed about the middle or towards the latter end of June. They will, by the laſt week in this month, be tolerably well rooted. They are to remain in the ſmall pots till the beginning of March, and then to be planted into the large pots, where they are to remain to blow. But the layers of the common kinds of carnations, ſhould, when taken off, be planted in a bed of rich earth. Let them remain in this bed to get ſtrength till October, November, or February, or March, obſerving to weed and water them occaſionally till that time; they are then to be taken up with balls, and planted in the borders.

Propagate Pinks by Piping, &c. — Still you may plant cuttings or pipings of pinks, &c. the beginning or middle of this month for propagation, in the manner related in June, taking the young ſhoots of the year: they will yet take root freely.

Tranſplanting Perennial Plants. — Tranſplant, where it was not done in June, the perennial and biennial plants, which were ſown in March or April, &c. The wall-flowers and ſtock July flowers, in particular, will now want tranſplanting from the ſeed-bed, and alſo the ſweet-williams, columbines, Canterbury, or pyramidal bell-flowers, with the Greek valerian, tree-primroſe, ſingle ſcarlet-lychnis, and roſe-campions; French honey-ſuckles and holly-hocks, and all others of the perennial and biennial kinds. Let them remain here to acquire a proper growth and ſtrength for a final tranſplantation, next October, and November, or in the ſpring; then taken up with balls, and planted in the borders, or where intended; or ſome of the more curious may alſo be planted in pots: all of which will flower in perfection next year.

Tranſplant the ſeedling Ariculas and Polyanthuſes. — Tranſplant the ſeedling ariculas which were ſown laſt autumn, or early in the ſpring, as alſo the polyanthuſes that were ſown in the ſpring ſeaſon, for it is now time to remove them out of the ſeed-bed.

Take up bulbous Roots. — Take up bulbous roots where neceſſary to be done, agreeable to the hints given the two former months. Many ſorts will now be paſt flowering, and their leaves will be decayed, and may then be taken up in order to ſeparate the off-ſets from the principal roots. The crown imperials, lillies, bulbous iriſes, and narciſſuſes, and many other bulbs, will now be in a condition for this practice, and put them up till October or November, when the borders may be conveniently dug, and the roots regularly planted.

Trimming Flowering Shrubs and Evergreens. — Look at this time over the flowering-ſhrubs and evergreens; and, with a knife, let ſuch as are grown rude be trimmed. What is meant by this is, where the ſhrubs have produced ſtrong and rambling ſhoots, ſo that the different ſhrubs interfere with each other, let the ſhoots of ſuch ſhrubs be now either cut out, or ſhortened in ſuch a manner as to form the head of the plant ſomewhat regular; and alſo that every ſhrub may be ſeen diſtinctly without crouding upon one another.

Cutting down decayed Flower Stems. — Go now and then round the borders, and cut down the ſtems of ſuch flower plants as are paſt flowering. But this is now principally to be underſtood of the perennial and biennial fibrous rooted plants: the bloom of many of theſe kinds will now be paſt; and the ſtems ſhould always, according as the flower decays, (except where ſeed is wanted) be immediately cut down; then the plant, though paſt flowering, will appear decent. Let therefore the decayed ſtalks be cut down cloſe to the head of the plants, and at the ſame time clear each plant from any decayed leaves.

AUGUST.

Watering and general Care of Annual Plants in Pots. — Take care now of the annual plants in pots; they muſt in dry weather, be well ſupplied with water: let them be watered at leaſt three or four times a week: but in very hot dry weather they will need watering every day.

Propagate fibrous-rooted Plants. — Now is the proper time to encreaſe many of the double flowered and other deſirable fibrous rooted plants done flowering, by ſlipping and parting the roots; and the proper time to begin to do it is about the middle or latter end of the month. Many ſorts may now be encreaſed by that method; particularly the double roſe-campion and catchfly, double ſcarlet lychnis and double rocket; alſo the double ragged robin, batchelor's button, gentianella, polyanthuſes, auriculas, and ſeveral other ſuch like kinds of fibrous rooted perennials. The method is this: where the plants have grown into large tufts, let the whole of each root be taken up entirely out of the earth; then let it be parted, or divided into as many ſeparate plants as you ſhall ſee convenient, but not into very ſmall ſets; but in parting them, take care to do it in ſuch a manner as every plant or ſlip ſo ſeparated may be properly furniſhed with roots. Theſe will all take root in a very ſhort time, get ſtrength and make tolerable good plants by the latter end of October and November: at that time, or in the ſpring, they may be taken up with balls, and planted ſome in pots, and the reſt into borders. They will all blow next ſummer.

Saxifrage.—This is now a proper time to propagate ſaxifrage. The double white ſaxifrage flowers in the ſpring ſeaſon, and makes a beautiful appearance. They are eaſily propagated by ſmall off-ſets from the roots, which they produce plentifully: they are generally planted in pots, but may alſo be planted in the borders or beds, planting ſeveral of its ſmall roots in a place that the flowers may come up in bunches: otherwiſe they will make but little ſhew; and they will flower next year.

Aricula and Polyanthus Seed. — This is a good time to ſow ariculas ſeed; and it will alſo be proper to ſow the ſeed of polyanthuſes. Let the ſeeds be ſown pretty thick, and cover them about a quarter of an inch deep. The boxes or pots muſt then be ſet where only the morning ſun comes, ſtand there till the end of next month, and then be removed where they can have the full ſun.

Plant out Pink Pipings, &c.—When the pink pipings or cuttings, planted in June, are well rooted and advanced in growth, let them be thinned out and planted, and give proper waterings; the reſt will be fit to plant out next month, and they will all acquire proper ſtrength for flowering moderately the following year, but in greater perfection the ſecond ſummer. They will obtain a good buſhy growth by the end of October, when, or in November, or the following ſpring, ſome of the ſtrongeſt may be tranſplanted with balls into the borders, &c.

Sow Seeds of bulbous Flowers. — Sow ſeeds of bulbous flower-roots, to obtain new varieties. The proper time to do this, is ſome time between the twentieth and laſt day of the month. The ſorts proper to be ſown are, tulips, hyacinths, narciſſus, iris, crown imperials, fritillaris, and lilies, the ſeeds of martagons, crocuſes, and other bulbs. Theſe ſeeds may be ſown either in beds or in boxes, &c. The convenience of boxes or pots is, they can be removed readily to a different ſituation as the ſeaſon requires. The boxes for this purpoſe muſt be about fifteen or eighteen inches broad, and ten or twelve deep, or large wide pots. They muſt be filled within an inch and an half of the top, with fine light earth, making the top ſmooth; then ſow the ſeeds thereon moderately thick, and cover them with ſifted earth about half an inch deep. The next ſummer, at the ſame time, the roots are to be removed again, and muſt then be ſet three or four inches each way apart. Thus theſe ſeedlings are to be treated every ſummer till they are brought to a ſtate of perfect flowering; obſerving, at each removal, to allow more and more room. When they are brought to a condition of flowering, they are then to be managed as the other old roots. Though it will be ſeveral years before ſome of the roots arrive to that ſtate, particularly the tulips, which never begin to ſhew a flower till the ſixth or ſeventh year; the advantage of raiſing this and other choice bulbs from ſeed, is, that when the ſeedlings are raiſed to a flowering ſtate, and begin to break into ſtripes or variegations, there will every year appear among them many new flowers. This is the advantage of raiſing them from ſeed; and likewiſe among the new flowers, there will ſometimes be ſome that greatly excel, by the luſtre of colour, tinges, and regularity of ſtripes, &c.

Sow Anemone Seeds, &c.—Sow anemone ſeed, and the ſeed of ranunculaſes, and ſpring cyclamens. It will be moſt adviſeable to ſow theſe ſeeds principally in boxes or large wide-mouthed pots. The pots or boxes to be filled with rich, but very light earth.

Remove bulbous Roots.—This is ſtill a proper time to remove, where required, ſeveral ſorts of late flowering bulbous roots, now out of bloom, ſuch as the roots of martagons and red lilies; the ſtalks and leaves of white lilies alſo now decay; and that is alſo the moſt proper time to remove theſe bulbs. When the roots are taken up, the off-ſets muſt be all ſeparated from them; and when this is done, the principal roots may either be planted again now in the proper places, or may be dried and cleaned, and put up till October, and then planted.

Tranſplant Perennials.—Tranſplant into nurſery-beds, ſuch ſeedlings of wall-flowers, ſtocks, and ſweet-williams: alſo columbines, ſcabiouſes, and other ſeedling perennial and biennial plants as are ſtill remaining in the ſeed-bed. Theſe ſhould be tranſplanted in moiſt weather; and the ſooner the better, that the plants may have time to root, and get ſome ſtrength before winter. When the plants have ſtood in the above beds or borders, two months, or thereabouts, or till the end of October, or November, &c. or next ſpring, a quantity may then be tranſplanted into the flower borders; and other parts of the pleaſure ground to remain to blow next year.

Gather Flower Seeds.—Gather the ſeeds of ſuch flowers as are now ripe, in a dry day; ſpread them on mats to dry in an airy place where the ſun can come. When they are well hardened, beat or rub them out, and put them in paper or canvas bags, or into boxes, till the ſeaſon for ſowing them.

SEPTEMBER.

Planting Hyacinths and Tulip Roots, &c.—In the third or fourth week in this month, it will be time to begin to plant the choice hyacinth and tulip roots for an early ſpring bloom. Any other bulbous roots may likewiſe be planted towards the middle and end of this month.

Ranunculuſes, &c.—About the middle or towards the latter end of this month, begin to prepare the beds for the beſt ranunculuſes and anemone roots; and any time after the twentieth of the month to the end of October, is the time to plant them; but they ſhould not be planted cloſe, for when the plants ſhoot up in a crouded manner, they draw each other up weak, and the flowers never grow ſo large, nor the different varieties ſhew themſelves to ſuch advantage, as when they ſtand more diſtant.

Sow Anemone and Ranunculus Seed.—This is ſtill a proper time to ſow the ſeeds of anemones and ranunculuſes, where it was not done in Auguſt. For that purpoſe, fill ſome pots, boxes, or tubs, with rich light earth, and cover them not more than a quarter of an inch thick. The plants ſhould be protected in winter, in time of great rain or hard froſt. About the Michaelmas twelvemonth, they ſhould be tranſplanted into a bed of common earth, and in the ſpring following they will flower; when perhaps, they will afford you ſeveral new flowers that are double, and of fine colours.

Carnation Layers.—Take care now of the carnation layers: where there are any ſtill remaining on the old plants, let them be tranſplanted ſome time before the middle of the month, that they may have time to take good root before winter.

Auricula Seed.—The ſeed of auricula may ſtill be ſown when not done in Auguſt. Theſe ſeeds ſhould at this time be ſown in large wide pots, or in boxes filled with earth. Theſe auricula plants raiſed from this ſowing, will flower the next ſpring twelvemonth.

Tranſplant Perennial Plants—Tranſplant into borders, towards the latter end of this month, ſome of the ſtrongeſt perennial plants which were ſown in the ſpring or the beginning of the ſummer. Theſe may be ſafely tranſplanted any time after the middle of the month: particularly carnations, pinks, and ſweet-williams; and alſo the ſeedling wall-flowers, ſtock July flowers, and columbines, with many other ſorts.

Sowing Seeds of bulbous Flower Roots.—The ſeeds of tulips may ſtill be ſown, and alſo the ſeeds of hyacinths and crown imperials, with the ſeeds of fritillarias, and of moſt other bulbs. Then ſow the ſeeds ſeparately on the ſurface, and tolerably thick, and cover them with light ſifted earth, near half an inch deep or thereabouts.

Plant Box.—Now is the time to begin to plant box where new edgings are to be made; but this ſhould not be done principally in any conſiderable extent till towards and after the middle of the month. There is no time in the year in which box will take root better than this; but as ſoon as an edging is planted it will be proper to give an hearty watering. This is alſo a good time to repair any former planted box edgings where wanting.

Propagate Fibrous-rooted Plants.—This is the time to ſlip and plant out many kinds of fibrous-rooted plants, to encreaſe them; ſuch as roſe-campion, ſcarlet lychnis, catchfly, and campanulas. When theſe plants are grown into large tufts, it will be proper to take the roots entirely up, and part them, and plant ſome of the beſt ſlips again in the borders or places where they are to flower.

Tranſplanting Pionies and other knob-rooted Plants.—This is alſo a good time to tranſplant pionies, and alſo to part their roots; and the different ſorts of flag iriſes, monk's-hood, fraxinella, and all other ſuch like plants, may now be taken up and parted where neceſſary, and tranſplanted into places where wanting.

The Care of Plants in Pots.—Take good care now of all ſuch ſhrubs as are in pots, particularly the more tender kinds, to defend them in ſevere weather. In order to protect the roots the better from froſt, let the pots of ſhrubs in general, if not done before, be plunged to their rims in a dry warm ſpot. And the more tender and curious kinds, ſuch as any ſmall arbutus, magnalias, ciſtus, &c. in pots, ſhould be placed in deep frames to have occaſional ſhelter of covering in froſty weather. By plunging theſe plants in the earth it prevents the froſt entering the ſides of the pots to hurt their roots; and in very hard froſts it will be proper to lay ſome dry long litter lightly over all their tops; but this muſt always be taken immediately off when the froſt is leſs ſevere. But where there are any frames to ſpare, and the pots with the above fibrous-rooted plants placed in them, and defended occaſionally with glaſſes or other covering, it will be of great advantage. If the pots where the auricula plants are in, are not protected, they may, in very wet weather, be occaſionally laid down on one ſide, with the tops towards the ſun, to protect the plants better from too much moiſture, which, though but a ſimple expedient, is better than to leave them upright to receive the rain, &c. all the winter.

Carnation Layers.—Carnation layers, which were in Auguſt, or the laſt month, planted in ſmall pots, ſhould in the laſt week in this month, be placed where they can be readily defended in bad weather; but when the weather is dry and mild, let the plants at ſuch times have the advantage of the open air conſtantly.

Tranſplanting fibrous-rooted Flowering Plants.—Now tranſplant into the borders or places where wanted, all ſorts of fibrous-rooted perennial and biennial plants. Theſe ſorts of plants will now take root freely, and in a ſhort time. The ſorts proper to plant now are roſe campions and ſweet-williams, campanulas and catchfly, and you may alſo plant rockets, bachelor's buttons, double feverfew, ſcarlet lychnis and lychnideas. Double ſweet-williams, double rockets, double roſe campion, and the like, ſhould be planted in pots, and removed to ſome place where the plants can be ſheltered in ſevere weather. Theſe double flowers deſerve particular care. Now alſo ſlip and plant polyanthuſes where wanted; alſo double daiſies, double chamomile, violets, London pride, thrift, hepaticas, gentianelli, ſaxafrage, columbines, monk's-hood, Canterbury bells, fox gloves, tree primroſe, Greek valerian, ſcabiouſes, and ſuch like kinds. This is a good ſeaſon to plant golden rod, Michaelmas daiſies, everlaſting ſun-flowers, French honeyſuckles, and hollyhocks. The laſt mentioned plants grow very tall, and are fitter to be planted in the clumps among flowering ſhrubs, than in narrow borders.

Parting the Roots, and propagating various fibrous and knob-rooted Plants.—Where golden rod, everlaſting ſun-flowers, Michaelmas daiſies, and ſuch like rampant growing fibrous-rooted perennial plants, have ſtood in one place ſeveral years without tranſplanting, their roots will have ſpread conſiderably, and will be increaſed to very large bunches. Where that is the caſe, the roots ſhould now be taken up, and every main root divided into ſeveral parts, or ſeparate plants; and then ſome of the beſt ſhould be immediately planted again in the places allotted them. This is alſo ſtill a good time, where not done before, to part the roots of many other fibrous-rooted plants that have grown into large bunches.

Planting all Kinds of bulbous Flower Roots.—This is now a moſt eligible ſeaſon to plant almoſt all ſorts of bulbous and tuberous flower roots which were taken up when their leaves decayed, which by this time, when any bulbous roots are to be planted in aſſemblage with other flowers, it is much the beſt way to place them in patches; that is to ſay, in a ſmall ſpot of ſix or eight inches diameter, to plant four or five roots; placing one in the middle, and three round the edge; and ſo to plant the different ſorts in ſeparate patches, at the diſtance of one, two, or three yards. This method of planting bulbous rooted flowers in patches in the common borders, makes a very pleaſing variety in the flowering ſeaſon.

OCTOBER.

This is a very good time to plant the roots of ranunculuſes and anemones; alſo crocuſes and ſnow drop roots which were taken out of the ground in ſummer. Plant narciſſus and jonquils; and this is alſo a proper time to put in the roots of bulbous and Perſian iriſes, frittillarias, and the roots of martagons and orange lilies, and all other ſuch like bulbous roots as were taken up when their leaves decayed in ſummer.

Prune Flowering Shrubs, Evergreens, &c. — Prune roſes and honeyſuckles ; and this is alſo a proper time to prune all other ſorts of flowering ſhrubs and evergreens. Where any branch advances in a ſtraggling manner from the reſt, let that be cut ſhorter ; obſerving, if poſſible, to prune it cloſe to a young ſhoot, leaving that ſhoot for a leader to the branch ; and let every ſhrub be kept to a ſingle ſtem.

Plant and tranſplant hardy deciduous Flowering Shrubs and Ornamental Trees. — Now is the time to begin to plant, in places where wanted, all ſorts of hardy flowering ſhrubs ; ſuch as roſes, gelderroſes, lilacs, and honeyſuckles. Plant alſo where wanted, laburnums, ſyringas, althæa, frutex, jaſmines, privets, double-bramble, flowering raſpberry, the double bloſſom cherry, bladder-ſena, ſcorpion-ſena, ſpiræas, and hypericum frutex ; it is now alſo a proper time to plant mezereons, the double-flowering peach and almonds, the cornelian cherry, double hawthorn, and ſcarlet horſe cheſnuts. You may alſo now plant bladder ſena, ſcorpion ſena, althæa frutex, and ſpiræa frutex, with the double flowering cherry, jaſmines, gelder-roſe, and all other hardy ſhrubs and trees. But more particularly evergreens, will have finiſhed their years growth, determinable by their leaves decaying : and from that time to the middle or end of March, you may in open weather, tranſplant all kinds. Where it is intended to plant them in clumps, or any continued plantations, in the ſhrubbery order, let the ſhrubs in general be ſet at leaſt five or ſix feet diſtant from one another ; and ſuch plants as are of an humble growth, ſhould not be planted promiſcuouſly among tall growing plants ; for was that to be practiſed, the low plants would be loſt to view. This is the method of order that ſhould be practiſed in planting and decorating the clumps or quarters of the ſhrubbery ; ſtrait lines are not to be regarded, but rather to be avoided ; but ſome regularity muſt, notwithſtanding, be obſerved both with regard to the diſtance and advantageous diſpoſition of the different ſorts of plants.

Planting Evergreens Trees and Shrubs. — Evergreen ſhrubs or trees of moſt ſorts may alſo now be planted ; or may be removed any time of this month, and the ſooner the better. But, in particular, the ſtrawberry-tree or arbutus, laurel, Portugal laurel, lauruſtinus, pyracantha, phillyreas, alaternus, bays, ciſtuſes, evergreen-oaks, hollies, and magnolias, pines, firs, cedars, cypreſs, and many others.

Planting Evergreens to hide Walls, &c. — Phillyreas, lauruſtinus, and laurel, are proper ſhrubs to plant any where near a houſe, &c. to hide any rugged or unſightly naked walls, or other buildings. Theſe plants are a beautiful evergreen, ſummer and winter, they are alſo very hardy, and their growth is quick and regular ; and where wanted for the above purpoſe, this is a proper time to plant them. They muſt be planted cloſe to the wall, three or four feet aſunder, and their branches muſt be regularly ſpread and trained to the wall in the manner of a wall-tree ; they will ſhoot in a quick but regular manner, and their beautiful green leaves will effectually hide the moſt deformed or ill-looking wall, &c. The pyracantha is alſo a pretty ſhrub to plant againſt a wall, by reaſon of its cluſters of beautiful and red berries, which make a handſome and very agreeable appearance in autumn and winter. The arbutus, or ſtrawberry-tree is alſo ſometimes planted to hide a diſagreeable looking wall. This is a beautiful plant, and makes an agreeable figure in any place, and at all ſeaſons, but particularly in this and the two preceding months, when it is loaded with its fine red ſtrawberry-like fruit. But theſe plants make the beſt appearance when planted detached in the clumps or borders, lawns, &c. and ſuffered to grow in their natural way. Or theſe arbutus ſhrubs, being planted, detached or ſingly, upon graſs lawns, &c. kept to ſingle clean ſtems, and regular heads, they have a beautiful effect.

General Method of planting Trees and Shrubs. — In planting the various kinds of ſhrubs and trees in the ſhrubbery, &c. one general method ſerves for the whole ; open for every plant a circular hole wide enough to receive the roots freely every way, and about a ſpade deep, or as the root requires, and let the bottom be well looſened. Then get the plants and prune the end of all long and ſtraggling roots ; and cut away ſuch roots as are broken, damaged or dead : alſo any irregularities of the head ; then place the plant in the hole, and ſee that it ſtands upright.

Tranſplant Foreſt and Ornamental Trees. — Foreſt-trees of all ſorts may now be ſafely tranſplanted from the nurſery, &c. for any intended plantations, towards the latter end of this month ; ſuch as elm, oak, beech, birch, maple, aſh, lime, and plane trees ; alſo alder, poplar, pines, firs, cedars, cypreſs, larches, and almoſt all other ſorts, both of the deciduous and evergreen foreſt and ornamental trees. But theſe and all other foreſt trees, may be tranſplanted in mild weather any time between this and Chriſtmas: obſerve the ſame method in planting theſe ſorts, as obſerved in the general method of planting ; deſcribed in Auguſt and at the diſtance and order of arrangement as hinted in March.

Propagating by Layers, Hardy Trees and Shrubs. — Now make layers of all ſorts of hardy trees and ſhrubs to propagate them. This may be done any time in this month, and many ſorts of trees and flowering ſhrubs are to be propagated by that method ; the method is eaſy, and the trouble is not much ; beſides, it will be well repaid in a twelve-month's time with numbers of new plants. Almoſt any tree or ſhrub that ſheds its leaves in winter, may be raiſed by layers ; and in the hardy kinds, this is the beſt time to perform that operation. The method of laying is this : dig round the tree or ſhrub and bend down the pliable branches, lay them into the earth, and ſecure them there with hooked or forked ſticks ; lay down all the young ſhoots on each branch, and cover the body of them about four or five inches deep, leaving the tops of each at leaſt two, three or four inches out of the ground, according to their different lengths. Thus they are to remain till this time twelvemonth, by which time they will be well rooted, and muſt then be tranſplanted. Obſerve it is the laſt ſummer's ſhoots that are the moſt proper parts to lay ; accordingly let ſuch branches as are beſt furniſhed with young ſhoots be brought down and the ſhoots layed down in the earth.

Tranſplanting Layers. — Now is the time to take off and tranſplant the layers of all ſuch ſhrubs and trees as were layed laſt year ; let their roots be pruned.

Propagating Roſes aud other Shrubs by Suckers. — Tranſplant ſuckers of roſes ; it is by ſuckers from the root that moſt ſorts of theſe ſhrubs are increaſed ; theſe being digged up carefully with roots, will make good plants in one or two years time. Lilacs are alſo generally encreaſed by ſuckers, which ſhrub ſeldom fails to yield plenty every year.

Propagating Flowering Shrubs by Cutting. — Plant cuttings of honeyſuckles : all the ſorts of theſe ſhrubs may be propagated by that method, for the cuttings of the young ſhoots will put out roots very freely, and make pretty plants in one year. Many other ſorts of hardy ſhrubs and trees are to be raiſed from cuttings, and this is the time to plant them. Obſerve, it is the laſt ſummer's ſhoots that are to be uſed for cuttings ; let ſtrong ſhoots be choſen, and ſhorten them to about nine, ten or twelve inches in length. Let every cutting be got half way into the ground. Laurels and Portugal laurels are propagated principally by cuttings, and this is a very ſucceſsful time to plant them.

NOVEMBER.

General Care of Flower Plants. — Take care now to protect the choice flower plants and roots from froſt, great ſnows, and heavy rains ; all of which would damage many ſorts of curious roots and plants ; obſerving the following general directions in the particular ſorts. The choicer kinds of auricula and all the valuable plants in pots, muſt now be well defended in very wet weather, great ſnows, and hard froſts. If theſe plants are placed in frames, as was directed two months ago, let the glaſſes be kept conſtantly over them in bad weather, or if they are in a bed arched over with hoops, &c. let mats or canvas be drawn over them in ſuch weather, or in default of ſhelters, lay the pots down on one ſide in very wet or ſnowy weather. But when the weather is mild and dry, let the plants be conſtantly uncovered.

Clear the Borders. — Clear the borders from all dead annual plants, pulling them up by the roots ; ſuch as African and French marigolds, lavateras, China aſters, and all other of the like kinds, for theſe never ſurvive to flower again. Cut down all the dead ſtems or decayed flower-ſtalks of perennial plants, and let the borders be well cleared from leaves of trees and all ſorts of rubbiſh and litter. This prevents the growth of weeds, and renders the borders clean and decent for the winter ſeaſon. When the borders are perfectly clear, go round and ſee where any ſorts of perennial plants are wanting, and ſet down a ſtick in each place for a mark.

Planting Perennial Plants. — Many ſorts of perennial plants may ſtill be planted ; ſuch as the double ſcarlet lychnis, double roſe campion, double rocket, catchfly, campanula, bachelor's buttons, and the like. Likewiſe plant, where wanted, ſweet-williams, wall-flowers, ſtock July flowers, columbines, Canterbury bells, tree primroſe, Greek valerian, and honeſty. This is alſo a good time to tranſplant perennial ſun flower, golden rod, perennial aſters, hollyhocks, French honeyſuckles, monk's-hood, and pionees. Now you may likewiſe plant thrift, London pride, gentianella, double daiſies, winter aconite, polyanthuſes, auriculas, and primroſes, with many other ſorts. Obſerve to intermix the different ſorts in ſuch a manner that there may be an agreeable variety and regular ſucceſſion of flowers in every part.

Plant Tulips, &c. — This is ſtill a proper time to plant tulips, hyacinths, and various other hardy bulbous roots, and let it be done in dry open weather, and as early in the month as poſſible. Let theſe roots be planted in ſuch beds and borders as lie tolerably dry all winter ; for if the ground be too wet, the roots planted now would rot.

Plant Ranunculuſes and Anemones. The ranunculuſes and anemones ſhould alſo be planted in beds and borders of light dry earth, for a wet ſoil would be apt to rot theſe roots : let the choiceſt kinds of theſe roots be planted in beds for the convenience of protecting them in winter, and alſo in the ſpring, when they are in bloom. In planting theſe roots, let the ſame diſtance and manner be obſerved as in laſt month.

Planting Narciſſuſes and other Bulbs.—Narciſſuſes and jonquils, frittillarias, crown imperials, gladioles, bulbous-iris, ſtar of Bethlehem, lilies, and all other bulbous roots that are ſtill above ground, may now be planted, when time and dry open weather will permit.

Care of Seedling Plants.—Small young or tender ſeedling flower plants, or roots, alſo demand care at this unfavourable month, if it is not done in October. Such tenderiſh kinds as are in pots, or boxes, may now be protected, by placing the pots, tubs, or boxes, in a warm border, or may alſo plunge them in the earth; and in hard froſt, long ſtraw litter may be laid on the ſurface, and around the ſides; the ſame protection of covering may alſo be given to ſuch as are in beds. It will ſecure the young bulbs or other plants the better from hard froſts: and when the weather proves very ſevere, it will be adviſeable alſo to cover them with long litter or with mats.

The Care of New-planted Trees. — Take care now, if froſts ſhould ſet in, to protect the roots of the more curious new planted ſhrubs and trees, by laying ſtrawy mulch on the ſurface of the ground; but this is particularly to be underſtood of the more tender kinds. Likewiſe place ſtakes, and tie tall new planted trees and ſhrubs as ſtand in need of ſupport, eſpecially thoſe in expoſed ſituations; let this be done in due time, for it is a very material article; becauſe, while the wind rocks them at the roots, it prevents them putting out new fibres: or at leaſt, as ſoon as put out, where not ſecured with ſtakes, they are broken off, or much diſturbed by the firſt high winds.

Graſs Walks and Lawns.—Now let the graſs walks and lawns be poled and rolled, for at this ſeaſon the worms will throw up very faſt, and make the graſs every where very dirty. The long pliable pole ſhould therefore be often uſed in dry days, in order to break and ſcatter the worm-caſts about; and the graſs ſhould afterwards be rolled with a wooden or ſome other roller; which will not only render the ſurface firm and ſmooth, but will alſo make it extremely clean, for the ſcattered worm-caſts will all ſtick to the roller. This poling and rolling ſhould, in order to keep the graſs perfectly neat, be performed once a week, or a fortnight, during the winter ſeaſon. Chooſe the drieſt days to do this work. Now alſo let the graſs be thoroughly cleared every where from the fallen leaves of trees; and as there are now moſtly all down, let them be cleared away in every part of the garden.

DECEMBER.

Protecting New-planted Shrubs. — New-planted ſhrubs, and trees of the more tender, or choicer kinds, ſhould have their roots well protected in hard froſty weather, by laying mulch or long dungy litter a good thickneſs on the ſurface of the ground over the roots of each plant. This work is ſo neceſſary to ſuch of the more tender and curious kinds of ſhrubs and trees as were planted in autumn, that it ſhould not be omitted now, if it was in the former month.

Pruning Shrubs, Foreſt Trees, &c. and dig between them. — Now go over the flowering ſhrubs, and prune all ſuch as ſtand in need of that diſcipline; but let this be done in a ſkilful manner, with a knife, and not with garden ſhears. In doing this, all the very ſtrong long rambling ſhoots of the laſt ſummer's growth extending conſiderably beyond the general branches of the head, ſhould be taken off quite cloſe, or reduced to regularity; and where the branches are crowded in a very diſorderly manner, let them be pruned to ſome tolerable order; and cut out dead wood. Every plant ſhould be pruned in ſuch order, as it may ſtand clear of another: never ſuffering the branches of different ſhrubs to intermix with each other, for that ſpoils the beauty of all, except where any are intended to form a thicketty growth to overſpread the ground. When the ſhrubs are all pruned, let the ground be dug between the plants; and as you go on, take up all ſuckers, and ſhorten ſtraggling roots. It is now a proper time to prune all ſorts of foreſt trees where neceſſary, obſerving to trim up all large ſide ſhoots and boughs from the ſtem, and low ſtraggling under branches of the head, for that may be performed in froſty weather when little other buſineſs can be done.

Preparing Ground for Planting. — Now dig, when the weather will permit, the borders, beds, &c. in the flower-garden, and the clumps and other compartments in the ſhrubbery, where any kind of ſhrubs, trees, or plants are to be planted.

Preparing Compoſt for Flowers. — Break up and turn the heaps of compoſt for curious flowers, in pots, &c. obſerving to mix the parts well together. At this time you ſhould alſo bring in freſh ingredients to make new compoſt heaps, for theſe ſhould always lie the beſt part of a year before they are uſed for any purpoſe; the principal compoſts, for choice flowers, being any light rich earth, ſea ſand, &c. light ſandy loam and a ſmall portion of dry rotten dung; all well blended together in an heap.

Plaſh Hedges. — This is a proper time to plant any ſorts of hedges of the deciduous kinds particularly; ſuch as hawthorn, beech, elm, elder, horn-beam, herbery, privet, black-thorn, or ſloe; procure young ſets of two or three years old from the nurſery. Where fence hedges are grown up tall, rude, and thin, or naked at bottom, they ſhould now be plaſhed, or laid down in ſuch a manner as to render them thick in every part, performed by gaſhing the lower parts of the larger ſtems, &c. and lay them down horizontally between others left erect for growing ſtakes, cut even at top four or five feet high.

PART II. USEFUL GARDENING.

As the bounties of nature cannot be more beautifully diſplayed than in the vegetable creation, and as the utility of gardening amply compenſates for all our labour; we have in this conciſe practical treatiſe laid down in chronological order, directions not only for the gentleman, who exerciſes it for his amuſement, but likewiſe the induſtrious gardener, who follows it as a profeſſion. In order to effect which, we begin with January, and proceed forth a monthly diſplay of the buſineſs throughout the year.

Thus we hope to exhibit a pleaſing view of the product of every month in the vegetable creation, to the honour of the univerſal parent of nature, and benefit of mankind in general; many of whom may be thereby prompted to co-operate with a wiſe providence, in promoting his wiſe and ſalutary deſigns. In ſhort, it has been our care faithfully to ſelect the produce and inſtructions relative to the manures of each month in the year, as the moſt approved method of aſſiſting the memory without perplexing the mind.

MONTHLY CALENDER OF THE BUSINESS TO BE DONE IN THE FRUIT AND KITCHEN GARDEN.

JANUARY.—*FRUIT GARDEN.*

Pruning Apple and Pear Trees in Eſpaliers, and againſt Walls.—Where there are wall and eſpalier apple and pear trees yet unpruned, that work ſhould now be forwarded as much as poſſible, and may be ſafely performed upon all ſorts, without fearing any danger from froſt, even if it happens when performing the operation. Apple and pear trees being of the ſpur-bearing kind, and their mode of bearing ſimilar, one method of pruning anſwers for both; they producing their fruit upon ſhort natural ſpurs from the ſides and ends of the branches, and the ſame branches continue bearing for many years, increaſing their quantity of fruit ſpurs as they gradually advance in length; let it therefore be remarked, that in the general courſe of pruning thoſe trees, their branches and ſhoots are not to be ſhortened, but generally trained along horizontally to the eſpalier and wall, at their natural length, at leaſt as far as there is ſcope of room to extend them; never ſhortened except on particular occaſions, below explained; and the whole trained five or ſix inches aſunder. Keeping therefore this in mind, look over the general branches, and if the tree is young and in training, requiring a farther ſupply of young wood to form the head, retain a proper quantity of the beſt-placed laſt ſummer ſhoots at full length, and cut out all the ſuperfluous and irregular ones; but in full trained or old trees, ſtill retaining the former-trained or ſame individual bearing branches for many years, as long as they continue fruitful, extending them to the wall and eſpalier, without ſhortening, if room admits. In the courſe of this pruning have particular care to preſerve all the natural fruit-ſpurs; but cut away all thoſe formed of the remaining ſtumps of ſhortened ſhoots, for theſe rarely produce any thing but a confuſion of unneceſſary wood ſhoots every ſummer. Then train in all the remaining proper branches and ſhoots at full length, ſix inches aſunder, without reducing them in length either in the ſummer or winter pruning. By the above practice the ſhoots or branches of theſe trees, will about the ſecond or third year after they are laid in, begin to produce ſhort ſhoots or ſpurs (as they are generally termed) about an inch or two in length; ſome not above half an inch; and from theſe the fruit is produced. But if the branches of theſe trees were to be ſhortened, it would be cutting off the very part where bloſſom buds or ſpurs firſt begin to appear; and inſtead of thoſe fruitful parts, they would ſend forth a number of ſtrong wood ſhoots. This plainly ſhews, that the ſhoots which are intended for fruit-bearing muſt not be ſhortened; for if that is practiſed, the trees would conſtantly run to wood, and never produce any tolerable crop of fruit. If, indeed, there is a want of ſhoots in any part of theſe trees, then occaſional ſhortening is neceſſary. For inſtance, if there is any vacant part in the tree, and two, three, or more ſhoots, are requiſite to furniſh that vacancy, and only one ſhoot was produced in that part the preceding ſummer, that ſhoot, in ſuch a caſe, being now ſhortened to four or five buds, it, if ſtrong, will produce three or four lateral ſhoots the ſummer following.

Pruning and Nailing Plums and Cherries.—This is alſo a proper ſeaſon to prune and nail plums and cherries, either againſt walls or eſpaliers. Let it be obſerved, in the pruning of theſe trees againſt walls or eſpaliers, that, like the apples and pears, they being of the ſpur-bearing kind, producing the fruit upon ſhort natural ſpurs or ſtuds, emitted along the ſides of the branches, from two or three to many years old; you muſt accordingly retain the ſame branches many years for bearers, which muſt not be ſhortened in the courſe of pruning, but trained horizontally at full length, about five or ſix inches aſunder; and in every other reſpect the trees muſt be treated in the ſame manner as the apple and pear trees. But if ſhortening was generally practiſed to theſe kinds of fruit-trees, as is the caſe with many pruners, it would prove their manifeſt deſtruction in regard to preventing their fruitfulneſs.

General Obſervations in Pruning all the above Trees. — We obſerved above, that ſhortening the branches of apples, pears, plums, and cherry trees, was not proper in the general courſe of pruning; it however, in ſome particular caſes, is moſt neceſſary; for which take the following hints: For example then, when the trees, for walls and eſpaliers particularly, are only about one year old from the budding or grafting, either in the nurſery, or newly planted againſt walls or eſpaliers, with their firſt ſhoot immediately from the budding or grafting, at full length, it is proper to ſhorten or head down theſe ſhoots near the inſertion of the bud or graft, to force out lateral branches, which is called heading down the trees; but this ſhould not be done till ſpring, cutting them down to four or five eyes; which will procure lateral ſhoots near the ground, in order that the wall or eſpalier may be regularly furniſhed with branches from the bottom. After this the branches are to be trained along at their full length; if there appear to be ſtill more branches wanting, ſome of the moſt convenient of theſe laſt ſhoots may alſo be ſhortened, to promote their producing a farther ſupply of lateral branches, ſufficient to give the tree its proper form; for the great art is to encourage and aſſiſt young wall and eſpalier fruit trees in their firſt two or three years growth, to produce ſhoots in proper places, ſo as to cover the wall or eſpalier regularly with branches, from the bottom to the top.

But when the trees have acquired branches enough to effect the firſt proper formation of the head, they will afterwards naturally furniſh further ſupplies, to cover the wall or eſpalier regularly every way, to the allotted extent, without any farther ſhortening; except on particular occaſions, when a vacancy may happen in any part, according to the rule mentioned above, in the article of apples and pears. There is one thing farther to be obſerved in pruning apple, pear, plum, and cherry trees; and that is, when the trees have acquired branches enough to cover the wall or eſpalier, at the diſtance above mentioned, then all thoſe young ſhoots of the laſt ſummer's growth, that are not wanted in vacancies to form new bearers, muſt be cut off quite cloſe to the place from whence they ariſe, leaving no ſpurs but the fruit-ſpurs that are naturally produced, which every branch will be plentifully furniſhed with, if the above rules are obſerved.

Pruning and Nailing Peaches, Nectarines and Apricots. About the end of this month you may begin to prune peaches and nectarines, you may alſo prune and nail apricots. Before you begin to prune, it will be proper to un-nail the greateſt part of the ſmaller branches; then you can more readily uſe your knife, and alſo can conveniently examine the ſhoots, to ſee which are fit for your purpoſe, and which are not. In pruning theſe trees, obſerve to leave, in every part a due ſupply of the laſt ſummer ſhoots at moderate diſtances; that is, about four, five, or ſix inches aſunder, and in ſuch regular order as they may ſeem advancing one after another, quite from the bottom, as we have obſerved on former occaſions, in order that every part of the wall, from the bottom to to the extremity at every way of the tree, may be regularly furniſhed with them: for theſe ſhoots bear the fruit next year, and at the ſame time a proportionable ſhare of the two former years bearers, and naked old wood muſt be retrenched, to make room to train the young ſupply; for as theſe trees always produce their fruit upon the ſhoots of the laſt ſummer's growth, that is principally upon the one year's old ſhoots, and on no other, except occaſionally on ſmall ſpurs on the two or three years wood, but more generally the apricot; the pruner will by this know what he is to cut out, and what to leave, both in the young and old wood.

The next thing to be obſerved is, that all theſe retained ſhoots muſt now, for the general part, be more or leſs ſhortened; and this is done principally to encourage them to produce next ſummer, as well as fruit, a due ſupply alſo of bearing ſhoots, to bear fruit another year. For by ſhortening theſe ſhoots in the winter pruning, it makes them more certainly produce next ſummer a ſucceſſional ſupply of lateral ſhoots in proper places; and the ſhoots which are then produced, bear the fruit to be expected the year after that. But in ſhortening the ſhoots, mind to let every one be ſhortened according to its growth and original length; for inſtance, a ſhoot of about a foot long, may be pruned to about ſeven or eight inches, or a little more or leſs, according to its ſtrength; one of fifteen or eighteen inches, cut to about ten or twelve; and a ſhoot about two feet long, may be cut to about ſixteen or eighteen inches; and ſo in proportion to the length and ſtrength of the different ſhoots, leaving the ſtrong ſhoots the longeſt. Be careful, however, not to prune below all the bloſſom buds, except where you prune principally for wood. But ſuch peach, nectarine, and apricot trees as in general produce ſtrong and vigorous ſhoots, muſt be treated accordingly; the ſhoots of ſuch trees muſt be left ſomewhat cloſer than the diſtance above preſcribed, and muſt alſo be ſhortened leſs in proportion; ſome of the moſt vigorous ſhould be ſhortened but very little, and ſome not at all. This is the only method of pruning to bring a vigorous ſhooting tree, to a good order, ſo as to produce moderate ſhoots, ſuch as will bear fruit. By what is above hinted, the pruner will not be at a loſs to know in what manner peach, nectarine, and apricot trees are, according to their different growths, to be treated in the article of pruning; and the rule here mentioned is to be obſerved at all times in the winter pruning. Obſerve that where any of the ſhoots which are left to bear have produced any ſmall ſhoots from their ſides, they muſt be cut off: cut them cloſe to the principal ſhoot, for theſe would neither produce good fruit nor good wood.

Another thing is proper to be obſerved in pruning theſe trees, and that is, in ſhortening the ſhoots, to mind, if poſſible, to cut them off at a leaf or wood bud; diſtinguiſhable from the bloſſom buds by being long and flat, the others being round and ſwelling; or otherwiſe prune to a twin, bloſſom bud, meaning where two bloſſom buds ariſe at the ſame eye, having a wood bud between them; either of which rules being neceſſary to be obſerved in ſhortening, in order that each may produce a leading ſhoot next ſummer, forming a leader to the main ſhoots; for where there is a fair leading ſhoot produced at or near the extremity of a bearing ſhoot or branch, to draw the ſap more freely, ſuch a branch ſeldom fails to yield fair and well taſted fruit.

It will alſo be proper to remark one thing more in pruning theſe trees: that as we often ſee on the two-year old branches ſome ſhort ſhoots, or natural ſpurs, about an inch or two in length, and on the ſaid ſpurs there are frequently ſeveral bloſſom-buds, but in the apricot in particular, theſe fruit ſpurs frequently occur; now ſome people cut theſe ſpurs entirely off; but I declare againſt that practice; for ſome of theſe ſhort natural ſpurs will produce handſome fruit, both in apricots, peaches, and nectarines. But, on the other hand, it will be proper to leave only ſuch of theſe ſpurs as are well placed, and promiſe by the bloſſom-buds to bear fruit: and ſuch as are naked, and alſo ſuch as advance conſiderably in a fore-right direction, ſhould be removed. When you have finiſhed pruning any one of the above trees; let that be immediately nailed to the wall in a proper manner, before you begin to prune another; for it is much the beſt method to nail every tree according as you advance in the pruning.

But ſome direct to leave theſe trees un-nailed till the beginning of March; but this practice I would be far from recommending, for it not only looks ill to ſee the ſhoots hang dangling from the wall, but the froſt has alſo more power to affect the tender ſhoots, and the long vigorous ſhoots are liable to be broken by the winds; and, laſtly, by leaving the trees un-nailed till March, the bloſſom-buds will be then ſo much ſwelled, that many of them would be unavoidably diſplaced by nailing up the ſhoots. For the purpoſe of pruning and nailing wall trees in an effectual and neat manner, you ſhould be provided with a ſharp knife, moderately hooked at the point, and a ſmall narrow hand-ſaw, for the more readily cutting off uſeleſs old or large dead branches, and for the purpoſe of nailing, you ſhould have a very handy light hammer, a quantity of the proper garden-wall nails, made particularly for that purpoſe, which may be bought at any ironmonger's ſhop. The next requiſite is a quantity of cloth liſting, or ſhreds, and theſe ſhould be neatly cut into proper lengths and regular breadths; about half or three quarters of an inch is the proper breadth, but let none exceed an inch; for too broad ſhreds have a clumſy look, particularly on the ſmaller branches. Where neat nailing is obſerved, every ſhred ſhould be cut with even or ſquare ends, and not too long, for it looks ſlovenly to ſee long dangling ends hanging down.

Pruning and nailing Vines. — Vines either againſt walls or in the vineyard, ſhould now be pruned and nailed; and this may be done any time in this month. In pruning vines, you muſt obſerve to leave in every part a proper ſupply of the laſt ſummer's ſhoots to bear fruit the next year; and let all the irregular and ſuperabundant ſhoots, that are not wanted, be cut out cloſe; together with part of the former year's bearers, and old uſeleſs wood, which muſt now be cut out to make room for the bearing ſhoots or branches. For the laſt ſummer's ſhoots which are now left, will, in the ſpring, produce from every eye or bud, a young ſhoot, and on theſe young ſhoots the grapes are produced the ſame ſummer; for vines ſeldom produce bearing ſhoots from any but one year old wood. Therefore the main article to be obſerved now, is to leave a ſufficient ſupply of the laſt ſummer's ſhoots in every part regularly from bottom to top. Chooſe the ſtrongeſt and beſt ſituated ſhoots, with the ſhorteſt joints. The general rule is to ſhorten the ſhoots to three, four, five or ſix eyes or joints in length; which rule ſhould be always obſerved according to the ſtrength of the different ſhoots; and never leave the ſtrongeſt ſhoots more than five or ſix eyes, or joints; for when the ſhoots are left longer, they only fill the vines in the enſuing ſummer with more ſhoots than you can find room to lay in; and, beſides, the fruit upon ſuch ſhoots, would be ſmall and ill grown; in proportion, therefore it is beſt to ſhorten the ſhoots to the length above-mentioned; and the fruit upon theſe ſhoots will be found to grow large, and will ripen well, and one large bunch of grapes is at any time worth three ſmall ones. In ſhortening the ſhoots, mind to cut them about half an inch above an eye, and make the cut ſloping behind it. Let the branches or ſhoots in general be left ten or twelve inches apart, or more, but that at leaſt. Take care to prune in ſuch a manner as that there may always be a ſucceſſion of young branches towards the bottom to come in to ſupply the places of the old naked wood, which muſt be cut out occaſionally, as it becomes unſerviceable.

Fig-Trees. — Fig-tree pruning is adviſed to be deferred till next month, or *March*, where ſee the method explained.

Prune Gooſeberry and Currant Trees. — Gooſeberries and currants bear both on the young, one or two years wood, and upon the ſeveral year's branches, generally upon ſmall ſpurs emitted naturally all along the ſides; and in each winter pruning it will be required to cut out any caſual worn out, old, or irregular branches, and a proportionable ſupply of laſt ſummer's young ſhoots retained, and the reſt pruned out. In pruning gooſeberries, let them be always kept thin of branches, and theſe not permitted to grow ramblingly acroſs one another; but all pruned to regular order, ſo as the main bearers, or general branches and ſhoots ſtand ſix or eight inches diſtance at the extremities; and generally, either keep the middle ſomewhat hollow, cut out all the ſuperabundant lateral ſhoots of laſt ſummer, cloſe to the old wood, only retaining here and there a good one in vacancies, occaſionally towards the lower parts, to be advancing to a bearing ſtate, to ſupply the place of caſual worn-out bearers; and generally leave, where practicable, a terminating or leading ſhoot to each main branch: by no means ſhorten the ſhoots of theſe trees too much; for by cutting them very ſhort, they are made to produce a deal of wood, and but ſmall fruit, and being ſo full of wood as to exclude the ſun and free air in ſummer, the fruit cannot ripen well; and it likewiſe renders it troubleſome to get at the fruit, when fit to gather. Never clip the trees with garden ſhears, as is the practice of ſome ignorant perſons. Currant buſhes ſhould likewiſe be kept thin and regular, not ſuffering the branches to run promiſcuouſly acroſs each other; for when they are ſuffered to grow ſo irregular and thick, they deprive the fruit of the benefit of the ſun; for want of which it will be ſour and ill-flavoured obſerving nearly the ſame order of pruning as adviſed above for the gooſeberries.

Prune Raſpberries.—In pruning theſe plants, obſerve that a freſh ſupply of ſhoots ariſe from the roots every year in ſummer for bearing the ſucceeding year; for the ſhoots, when but one year old only, always produce fruit, and totally die in the winter following, thoſe of each year being ſucceeded by the ſucceſſional ſupply of young ſhoots of the laſt ſummer to bear the enſuing ſeaſon; therefore as the ſhoots which produced fruit laſt year will now be dead, they muſt be cut away cloſe to the ſurface of the ground, and leave ſtanding upon each root three or four of the ſtrongeſt ſhoots of the laſt ſummer's growth to bear fruit next year; but cut all the reſt off cloſe to the ſurface of the ground. Thoſe ſhoots which are left to bear muſt be each of them ſhortened; in doing of which you muſt cut off about one third or fourth of the length of each ſhoot, according to their ſtrength; obſerving, as they generally form a bend at top, it is proper to ſhorten them at or a little below the bending part; and if they are left longer, or that they ſtraggle wide and irregular from one another, may plait them together, either uprightly or archways, to ſupport them in an erect poſition. The ground ſhould then be digged between the rows; and, as you go on, the roots that do not belong to the ſtanding plants ſhould be taken away; and all ſhoots growing in the intervals dug up.

Prune Standard Fruit-trees.—Standard apple and pear-trees, and all other ſtandard fruit-trees, both in gardens and orchards, &c. may now have any neceſſary pruning, to reform caſual irregularities, very crouding branches, and to cut out any decayed wood and worn out bearers. Where any large branch grows in a rambling manner acroſs the reſt, let it be cut out. Where the main branches ſtand too cloſe ſo as to interfere with, and greatly crowd each other, let the moſt irregular growers be cut off. Let all dead wood and very old worn out branches be cut away in every part of theſe trees. By keeping the trees thin, and taking away all irregular growing and old caſual worn out branches, it is the only way to have large, fair, and well taſted fruit, and alſo to have handſome and laſting trees. Having cleared your trees from all uſeleſs branches, let the remaining ones be well cleared from moſs, if there be any on them.

JANUARY.—*KITCHEN GARDEN.*

The principal buſineſs at this ſeaſon in the kitchen garden is to continue to prepare ground for future crops, by manuring, digging, and trenching: protecting tender plants in frames and glaſſes, in froſty and other bad weather, making hot beds for early forcing, where required; and only a few articles are neceſſary to be ſowed and planted, and theſe principally in but ſmall portions on warm compartments, and in hot beds, for early crops. As it is the ambition of moſt gardeners, to excel each other in the production of early cucumbers and melons, all the preparations ſhould be attended to this month for that purpoſe; for being exotics of a very tender quality they require the aid of artificial heat under ſhelter of frames and glaſſes, until June or July, before they can bear the open air in this country. But by the aid of hot-beds, defended with frames and glaſſes, we obtain early fruit fit to cut in February, March, and April, &c. in the greateſt perfection. Obſerve, that in procuring theſe ſeeds for immediate ſowing, both of cucumbers and melons, it is adviſeable to have thoſe of two, three, or four years old, if poſſible, as the plants of which generally ſhew their fruit ſooner, as well as prove more fruitful than thoſe of new ſeeds, which are apt to run vigorouſly to vine, often advancing in conſiderable length before they emit a ſingle fruit.

Method of making up Hot Beds, and preparing the Dung for raiſing early Cucumbers, Melons, &c.

Provide a quantity of freſh horſe-dung, to make a ſmall hot bed for a ſeed bed, in which to raiſe the plants to a proper growth for ridging out into larger hot beds to remain to fruit: for this purpoſe a ſmall bed for a one or two light frame may be ſufficient, eſpecially for private uſe: in which caſe a good cart load of proper hot dung, or about twelve or fifteen large wheel barrows full, will be enough for making a bed of proper dimenſions for a one light box, and ſo in proportion for a larger. Having procured the dung, it muſt be previouſly prepared by ſhaking it up in a heap, mixing it well together, and let it remain eight or ten days to ferment; at the expiration of which time it will be arrived at a proper temperament for making into a hot bed.

Chooſe a place on which to make the hot bed, in a ſheltered dry part of the melon ground, &c. open to the morning and ſouth ſun: and it may be made either wholly on the ſurface of the ground, or in a ſhallow trench, of but from ſix to twelve inches deep, and four or five feet wide, according to the frame; but if made entirely on the ſurface, which is generally the moſt eligible method at this early ſeaſon, it affords the opportunity of lining the ſides of the bed with freſh hot dung quite down to the bottom, to augment the heat when it declines, and alſo prevents wet from ſettling about the bottom of the bed, as often happens when made in a trench, which chills the dung, and cauſes the heat ſoon to decay. Then, according to the ſize of the frame, mark out the dimenſions of the bed with four ſtakes; making an allowance for it to be two or three inches wider than the frame each way; this done, begin to make the bed according to the extent of the ſtakes, obſerving to ſhake and mix the dung well, as you lay it on the bed, and beat it down with the back of the fork, as you go on; but we would not adviſe treading it; for a bed which is trodden hard will not work ſo kindly as that which is ſuffered to ſettle gradually of itſelf: in this manner proceed till the bed is arrived at the height of three feet, or three and a half, which will not be too much, but let it be full three feet high: as ſoon as the bed is finiſhed to the intended height, let the frame and glaſs be put on; keep them cloſe till the heat comes up, then raiſe the glaſs behind, that the ſteam may paſs away.

Three or four days after the bed is made, prepare to earth it, previouſly obſerving if it has ſettled unequally; take off the frame and light, and level any inequalities; make the ſurface ſmooth, and put on the frame again, and lay in as much dry earth as will cover the bed all over about three inches thick: then fill ſome ſmall pots with rich dry earth, ſet them within the frame, put on the glaſs, and keep it cloſe, till the earth in the pots is warm.

Raiſing early Cucumbers and Melons.—The proper ſorts of cucumbers for early crops are: early ſhort prickly, early cluſter; the prickly, and early long prickly. The firſt two ſorts come earlieſt, but the laſt is conſiderably the handſomeſt fruit: if early melons are alſo required, the beſt are: romana melon, and Cantaloupe melon. Sow a few ſeeds in each pot, either of cucumbers or melons, or both, ſeparately, about half an inch deep. This done, place the pots in the middle of the bed, and draw ſome of the earth of the bed round each pot. Cover the glaſs every night with a ſingle mat only, for the firſt three or four nights after the ſeed is ſown, but as the heat decreaſes augment the covering: being careful in covering up, never to ſuffer the ends of the mats to hang down low over the ſides of the frame, which would draw up a hurtful ſteam, keep the plants too cloſe, and draw them up weak, and of a yellowiſh unhealthy like colour; obſerving likewiſe in covering up, that whilſt the great heat and ſteam continues in the bed, it may be proper, when the mats are put on in the evening, to raiſe one of the upper corners of the light half an inch, or a little more or leſs occaſionally, to give vent to the ſteam; ſuffering one end of the mat to hang down a little, juſt to defend the part where the glaſs is tilted.

Great care is requiſite that the earth in the pots have not too much heat, for the bed is yet very hot, which is the reaſon theſe ſeeds are adviſed to be ſown in pots; becauſe if any thing of burning ſhould appear, you can conveniently raiſe the pots farther from the dung, from which the danger proceeds, without diſturbing the ſeed or plants; and thereby prevent all injury from too much heat, provided you examine the bed every day, and give proper vent to the rank ſteam within the frame, while of a burning quality. In two, three, or four days after the ſeed is ſown, you may expect the plants to appear; when it will be proper to admit freſh air to them, by raiſing the upper end of the glaſs a little every day; and if the earth in the pots appears dry, refreſh it moderately with a little water that has ſtood in the bed all night, and nail a mat to hang down over the end of the glaſs that is raiſed, to break off the external cold air from the plants; but when the heat is more moderate, the glaſſes may be ſhut cloſe every night, obſerving to continue the admiſſion of freſh air at all opportunities in the day-time, and, if windy or a very ſharp air, to hang a mat before the place as above. On the day that the plants appear, ſow a little more ſeed in the the ſame bed, in the manner above-mentioned; for theſe tender plants being liable to ſuffer by different cauſes at this ſeaſon, it is proper therefore to ſow a little ſeed at three different times in the ſame bed, at ſhort intervals; for if one ſowing ſhould miſcarry, another may ſucceed. When the plants however, both of the firſt and ſucceeding ſowings, are two, three, or four days old, they ſhould be planted into ſmall pots, which pots muſt be placed alſo in the hot-bed, in the manner following:

Obſerve to fill the pots, the day before you intend to remove the plants, with ſome rich dry earth, and ſet them within the frame till the next day, when the earth in the pots will be warm; then let ſome of the earth be taken out, to the depth of an inch from the top of the pot; forming the middle of the remaining earth a little hollow; then with your finger carefully raiſe the plants up out of the ſeed-pots, with all the roots as entire as poſſible, and with as much earth as will hang about them, and place them in the other pots, in the hollowed part of the earth, with their roots towards the centre, and earth over their ſhanks near an inch thick, with ſome of the earth that was taken out of the pots; obſerving, if cucumbers, to plant three or four plants in each pot; if melons, two plants in each pot will be ſufficient, and if the earth is quite dry, give a very little water, juſt to the roots of the plants only; and directly plunge the pots into the earth on the bed cloſe to one another, filling up all the ſpaces between the pots with earth; and let every part of the bed within the frame be covered with as much earth as will prevent the riſing of the rank ſteam immediately from the dung, which would deſtroy the plants.

Be careful to examine the bed every day, to ſee that the roots of the plants do not receive too much heat: if any thing like that appears, draw up the pots a little, or as far as you ſee neceſſary for the preſervation of the plants, replunging them again to their rims when the danger is over. When the plants are fairly rooted, give them a little water in the warmeſt time of the day; and if performed when the ſun ſhines, it will prove more beneficial to the plants; let the watering be repeated moderately, according as the earth in the pots appear dry; and for this purpoſe, always have a quart bottle or two full of water ſet within the frame, to be ready to water the plants as you ſee them require it. If there is now a briſk growing heat in the bed, you ſhould, in order to preſerve it as long as poſſible, lay ſome dry long litter, ſtraw, waſte hay, or dried fern, round the ſides of the bed, and raiſing it by degrees as high on the outſides of the frame, as the earth is within. This will defend the beds from heavy rains or ſnow, if either ſhould happen: for theſe, if ſuffered to come at the bed, would chill it, and cauſe a ſudden decay of the heat, whereby the plants would certainly receive a great check. When there is a ſharp air or wind ſtirring, faſten a mat to the frame, ſo as to hang down over the place where the air enters; for this will alſo prevent the wind and cold air from entering immediately into the frame upon the plants, and they will reap the benefit of the air to a greater advantage than if the place was entirely expoſed.

About a fortnight, or a little more or leſs time after the bed is made, you will carefully examine the heat thereof, to ſee if it wants augmentation, and when the heat begins to decline conſiderably, remove the ſtraw, hay, or fern, from the front and back of the bed, if any was laid round it, as before adviſed, in which caſe apply a lining of freſh hot horſe-dung, to one or both ſides as it ſhall ſeem neceſſary: as ſoon as you have finiſhed the lining, cover the top with earth two inches thick; for this will prevent the rank ſteam of the new dung from coming up, and entering into the frame when the glaſs is tilted for the admiſſion of air, where it would prove very deſtructive to the plants; the lining will ſoon begin to work, when it will greatly revive the heat of the bed, and continue it in good condition a fortnight longer. Ten or twelve days after lining the ſides, remove the litter from the two ends of the bed, and apply alſo a lining of hot dung to each end, as above; it will again augment the heat for another fortnight to come.

By applying theſe linings of hot dung in due time, and renewing them as there ſhall be occaſion, you may preſerve the bed in a proper temperature of heat, of ſufficient duration to continue the plants in a free growing ſtate in the ſame bed, until they are of due ſize for ridging out into the larger hot-beds where they are to remain to produce their fruit. Obſerve, however, that where there is plenty of hot dung, and every proper convenience, you may, in order to forward the plants as much as poſſible, prepare a ſecond hot bed by way of a nurſery, about a fortnight after making the ſeed-bed in order to receive the plants therefrom in their pots when the heat begins to decline, plunging the pots in the earth as above directed; continuing to ſupport the heat of this bed as already explained, and in which the plants may be nurſed and forwarded, till they acquire a proper ſize for tranſplanting finally into the fruiting hot-beds. See *next Month*.

When the plants have formed their two firſt rough leaves, about two or three inches broad, and have ſhort runners, one or two joints, they are then of a proper ſize for ridging out into the large hot-beds, where they are finally to remain. See *next Month*. The plants muſt be ſtopt or topped at the firſt or ſecond joint, i. e. the top of the firſt advancing runner, when formed in the centre like a ſmall bud, ſhould be pinched off cloſe to the joint, as directed in February, which ſee.

Sowing Radiſhes.—At the end of this month, if the weather is open, ſow ſome ſhort topped radiſhes for an early crop, on a warm border, that lies well to the ſun, under a wall or other fence; and about the middle or latter end of the month, you may ſow more of the ſame ſort, and ſome ſalmon radiſhes to ſucceed the ſhort tops. But you ſhould not mix the ſeed of both ſorts together, but let each ſort be ſowed ſeparate; for the ſhort topped kind will come into uſe ſooner by a week than the ſalmon radiſh, even if both are ſown at the ſame time: beſides, the latter runs more to leaves than the former. There may be mixed and ſown with the radiſh, a ſprinkling of carrot-ſeed; for if the radiſhes ſhould fail, the carrots may ſucceed; and, if both ſucceed, there will be a double advantage; for when the radiſhes are drawn off for uſe, therere mains a crop of carrots, which will come in at an early ſeaſon: or, inſtead of the carrots you may ſow a ſprinkling of round-leaved ſpinach and a little lettuce, and when the radiſhes come off, theſe alſo come in. This is the common practice of the London gardeners. You ſhould ſow the radiſh ſeeds pretty thick at this ſeaſon, for when the plants begin to appear, the weather, if it ſhould prove ſharp, will cut off ſome, and the birds too being apt to attack them greedily, will deſtroy many; ſow the ſeed evenly over the ſurface, and either take it in with a large wide teethed rake, or, if ſowed in beds, cover it with fine earth, from the alleys, half an inch deep; then obſerving, eſpecially if appearance of froſt, that after the ſeed is ſowed, it will be of much advantage to ſpread ſome dry long litter over the ſurface, two inches thick, which will keep the ſurface warm, reſiſt the froſt, and greatly forward the germanation of the ſeed; which work of covering early radiſhes ſhould be continued occaſionally until the plants are farely in the rough leaves; this is the general practice of the London gardeners who thereby have them ready to draw for market plentifully in March.

Mint. — Make a ſmall hot bed for ſome mint, to come in early in the ſpring. The mint will appear in about a week or fortnight, and will be in a fine order for mint ſauce, &c. and either to uſe alone as a ſallad, or to mix among other ſmall herbs.

Parſley. — Sow ſome parſley ſeed, if open weather, about the middle, or towards the latter end of this month. There being two ſorts, the common plane leaved, and the curled leaved, the latter is preferable, the leaves being large, thick and buſhy, and is in much requeſt for garniſh to diſhes, though both ſorts are eligible, as pot herbs, &c. Theſe ſeeds may be ſowed in a ſingle drill round the edges of the kitchen garden quarters, or along the edge of the borders next the paths. This ſeed ſometimes lies ſix weeks or two months before it grows.

Carrots. — If the weather is open and dry, about the beginning, or any time of this month, let a warm ſpot of ground be prepared for a few early carrots: dig the ground a full ſpade deep, and break the earth well as you go on. In ſome families, young carrots are required as early as poſſible, and they may be forwarded by ſowing the ſeed in a moderate hot-bed; if you have no frame, or none at liberty, the bed may be arched over with hoops, and covered with mats occaſionally. When the plants come up, let them enjoy the free air in mild weather, and cover them in cold nights, whilſt young. And when an inch or two high, thin them to about three inches aſunder; and you will thus have young ſpring carrots for drawing in April and May.

Beans. — In the beginning of this month, if the weather is open, let ſome ground be got ready for a main crop of broad beans: The principal large ſorts are. Sandwich bean, toker bean, Windſor bean, broad Spaniſh bean, broad long podded bean. The Sandwich bean is an excellent ſort, and may be planted the firſt week in this month, if the weather permits. Alſo the toker bean, which is a very fine, and a good bearer. Set the beans either by a blunt-ended dibble, two or three inches deep, or drill them in that depth; and about four or five inches aſunder in the rows. For the early crops of beans, ſee *October*.

Peas. — Let ſome hot ſpur peas be ſowed the beginning of this month, for a full crop, on a warm piece of ground, to ſucceed the ſame ſorts which were ſown in October and November: the ſorts are: Charlton hot-ſpur, golden hot-ſpur, Reading hot-ſpur, Maſter's hot-ſpur, &c. But the two firſt are the earlieſt, and the others are proper to ſucceed them. At the ſame time alſo, you may ſow the firſt crop of marrowfat peas, and they will ſucceed the hotſpurs; for they will come into bearing as the others go off. This pea is much admired in moſt families: but the dwarf marrowfat is the propereſt for ſowing at this ſeaſon. See *October*.

Earthing up Peas and Beans. If you have peas and beans already up, one, two, or three inches high, or more, take advantage of a dry day, when the ſurface of the ground is dry, and draw ſome earth up to their ſtems. This ſhould not be omitted, for it will ſtrengthen the plants, and protect them greatly from the froſt.

FEBRUARY. — *FRUIT GARDEN.*

Forcing early Strawberries. About the latter end of this month, begin to make a hot-bed to raiſe early ſtrawberries: thoſe which are planted now in a hot-bed will produce fruit fit to gather in March and April. About the middle of this month, provide for that purpoſe as much new horſe-dung as will make a hot-bed about a yard high, for one or more three light frames. Let the dung be thrown in a heap, and let it lie about eight or ten days: in that time it will be in good condition to make the hot-bed. Previous to this, there ſhould be a proper quantity of ſtrawberry-plants potted, to place on the ſaid hot-bed; and this ſhould be done as directed in September: alpine and ſcarlet kinds are the beſt ſorts for this purpoſe, and ſhould be plants of two years old, of a full bearing ſtate. Having prepared the dung for the hot-bed, make it for one or more frames, about three feet high, and directly ſet on the frame and lights, to protect it from wet and draw up the heat ſooner: and when the violent heat is over, lay therein ſome earth, four or five inches thick; then bring in the plants, and plunge the pots into the earth up to the rims, and cloſe together as can be, filling up alſo all the interſtices between with earth. When all the pots are plunged, put on the glaſſes, and keep them cloſe till the ſteam ariſes in the bed, when it will be neceſſary to raiſe them a little behind, to let the ſteam paſs off. When the plants begin to puſh, let them have air at all opportunities, when the weather is favourable; for if they are kept too cloſe, the bloſſom will drop, without being ſucceeded to any tolerable crop of fruit, and let them be frequently refreſhed with a little water, and cover the glaſſes every night with mats.

In forcing ſtrawberries, the plants may be taken up out of the natural ground with balls of earth, and placed immediately in the earth of the hot-bed without potting them. However, when it is intended to force ſtrawberries, either in a common hot-bed, or in the hot-houſe, it would be a good method to plant ſome bearing plants in pots, in September, and ſo place the pots cloſe under ſome warm wall till the time they are to be placed in the hot-bed. But where there is the convenience of a pine-apple ſtove, or any kind of fruit forcing-houſe, or hot-wall, &c. you may raiſe plenty of early ſtrawberries in great perfection, with but very little trouble: having ſome bearing plants ready in pots, place them in the hot-houſe, any where near the glaſſes, giving frequent light waterings, they will fruit early in great abundance.

Tranſplanting Stocks to bud and graft upon. — Make new plantations of ſtocks to bud and graft the different kinds of choice fruit upon. Thoſe raiſed from ſeed, &c. laſt year, will now be ready for this practice. Let theſe be planted out as ſoon in the month as the weather will permit; plant them in rows thirty inches aſunder, and let them be planted at leaſt fifteen inches diſtance from one another in the row. They ſhould be planted by line, either dibbling in the ſmall plants, or the larger ones trenched, or holed in with the ſpade; or otherwiſe cut out ſmall trenches by line, placing the plants therein at the above diſtance, and turn the earth in upon their roots, and tread it gently to them all the way along.

Heading down budded Stocks. — Head down budded ſtocks, or ſuch young trees and ſhrubs that were budded the laſt ſummer: let this be done with a ſharp knife, obſerving to cut the head off about four inches above the place where the bud was inſerted. See the work of *Budding* and *Inoculating* in *July*.

Preparations for grafting. — Grafting may be begun any time after the fifteenth or twentieth of this month, provided the weather be mild. The ſorts proper to begin with are pears, plums, and cherries; and theſe kinds generally ſucceed beſt when grafted ſome time in the laſt fortnight of this month. Apples may alſo be grafted at the ſame time, or they may be deferred a fortnight longer. It ſhould be obſerved, that where grafting is to be done, you ſhould begin to prepare for it the beginning or middle of this month. The firſt thing to be done towards this work is to collect the grafts; and it muſt be obſerved theſe muſt be young ſhoots, ſuch only as were produced laſt year; for thoſe that are of more than one year's growth never take well. Theſe ſhoots or grafts you may begin to cut from the trees in the firſt or ſecond week of this month, in mild weather; and lay the lower ends of them in dry earth, in a warm border, till the grafting time, and if ſevere weather ſhould happen in the interim, cover them with long litter. The reaſon for cutting the grafts ſo ſoon, is, becauſe the buds will now begin to ſwell faſt; and if the grafts were not to be cut off in proper time, the buds would be too far advanced, and the grafts would by that means not take kindly with the ſtock, or at leaſt, not ſhoot ſo freely. Before we proceed to the methods of grafting it will firſt be neceſſary to mention what ſtocks are proper to graft the different kinds of fruit upon; for inſtance, apples ſhould be grafted upon ſtocks raiſed from the kernels of the ſame kinds of fruit, *i. e.* any kinds of apples; for the grafts or buds of theſe trees will not take well upon any other ſtocks.

It ſhould be obſerved, that for dwarf apple-trees, for walls or eſpaliers, or for ſmall ſtandards, they ſhould generally be grafted upon codlin apple-ſtocks, raiſed either from ſuckers from the root, or by cuttings or layers: for the ſtocks raiſed from theſe are never ſo luxuriant in growth as thoſe of the larger growing apple-trees; and, conſequently, trees grafted upon ſuch ſtocks, will be ſlower in growth, and can more eaſily be kept within due compaſs, ſo will anſwer the purpoſe for dwarfs, for eſpaliers, &c. much better than thoſe grafted on any other ſtock. Or if required to have them of ſtill more dwarfiſh growth for ſmall gardens, may uſe ſtocks of the Dutch paradiſe apple. But for the general ſupply of apple-ſtocks for common ſtandards, and large eſpalier trees, &c. they are raiſed principally from the ſeed of any ſort of apples or wild crabs. The time for ſowing the kernels of apples for ſtocks, is either in November or February; but if not ſown in November, they muſt be kept in ſand till this month. The plants will come up in five or ſix weeks, and in the autumn or ſpring following, ſome of the largeſt plants ſhould be drawn out and planted in nurſery-beds; and in the ſecond or third year after they will be in order to graft upon for dwarfs; but for ſtandards, let them be four or five years old, particularly if you intend to graft them at the height of four, five, or ſix feet; or may occaſionally graft for ſtandards, as low as is commonly practiſed for dwarfs, and to train up one ſtrong ſhoot from the graft, till it is five or ſix feet high, and then topped at that height to make it put out branches to form the head. Pears are generally grafted or budded upon ſtocks raiſed alſo from kernels of any of their own kinds of fruits; likewiſe by grafting them upon quince-ſtocks, which ſtocks are generally raiſed by ſeed, cuttings, layers, or ſuckers, and the pears grafted or budded upon theſe ſtocks are very proper for walls or eſpaliers. Sometimes alſo pears are grafted upon white-thorn ſtocks; but this is not ſo commonly practiſed, as theſe ſtocks have an ill effect on ſeveral ſorts of the fruit. The ſeaſon for ſowing the kernels of pears to raiſe ſtocks, and the tranſplanting, and time of grafting, is the ſame as mentioned above for apples.

Cherries are propagated by grafting or budding them upon ſtocks, raiſed from the ſtones of the common black or red cherry, or upon ſtocks raiſed from the ſtones, of any other kind of theſe fruit; but the two firſt are moſt eſteemed for that purpoſe, becauſe they generally ſhoot much freer than any other. The ſeaſon for ſowing the cherry-ſtones for raiſing ſtocks, is October or November, or in the ſpring; but when not ſown till ſpring, they muſt be laid in boxes of ſand all the winter, and muſt be ſown in this month. The ſtocks will be ready to tranſplant the firſt or ſecond year after ſowing, and the ſecond year after that will be fit to graft or bud, if for dwarfs, for walls, or for eſpaliers; but if for ſtandards, they muſt be ſeveral years old, run up with tall ſtems; for ſtandard cherries are generally grafted or budded at the height of five or ſix feet.

Plums are alſo grafted or budded upon plum ſtocks; that is ſtocks raiſed by ſowing the ſtones of any of the common ſorts of the ſame fruit; alſo raiſed occaſionally by ſuckers, ſent up from the roots of any kinds of plum-trees. The time for ſowing the ſtones to raiſe the ſtocks, is either in autumn or ſpring; but when they are not ſown till ſpring, they muſt be preſerved in ſand till that time, and the middle of this month is a good time to ſow them. Theſe ſtocks will be fit to bud or graft upon in the third, fourth, and fifth year after ſowing. It muſt be obſerved the ſtocks muſt be tranſplanted, ſome of the largeſt of them in the autumn or ſpring after ſowing, and in two or three years after will be fit to bud or graft upon. Let the ſtocks for grafting, both of fruit-trees and others, be always of the ſame family or genus as that of the reſpective trees which are to be grafted.

Note, Stocks raiſed from ſeed, being moſtly of a ſtronger growth, are commonly called free-ſtocks.

General Obſervations for performing the Work. — There are ſeveral methods of grafting, but we ſhall only take notice of three, which are practiſed with the greateſt ſucceſs, ſuch as Whip-grafting, Cleft grafting, and Crown-grafting. Previous to grafting, you muſt be provided with a proper grafting knife; a quantity of ſtrong baſs ſtrings for bandages, to tie the ſtocks and grafts firmly together; and ſome well wrought clay, to clay them round over the tying, to ſecure them from the air and wet. Obſerve, that the ſtocks intended to be grafted, muſt, previous to the inſertion of the graft, be headed down; which, if intended for dwarf trees, for walls or eſpaliers, muſt be headed pretty low; i. e. within five or ſix inches of the ground; but if for ſtandards, they may either be headed at five or ſix feet high; or at one, two, three, or four feet, for dwarf or half ſtandards: or occaſionally for ſtandards, ſome may be headed as low as directed for dwarfs, particularly apples and pears, and ſo train up one ſtrong ſhoot from the graft for a ſtem, till it is five or ſix feet high; then topped or cut off at that height, to cauſe it to throw out branches to form the head.

Whip-grafting. —This kind of grafting is practiſed with the greateſt ſucceſs, upon ſmall ſtocks, from about a quarter or one third of an inch; to half an inch, or near an inch in diameter: but commonly prefer ſmall ſtocks of about half an inch, or nearly equal in ſize with the grafts; and the method of performing the work is this:

Have your cions or grafts, &c. ready; then begin the work by cutting off the head of the ſtock, at a convenient height, according to rules above hinted; this done, fix upon a ſmooth part of the ſtock, where headed off, and there pare off the rind with a little of the wood in a ſomewhat ſloping manner upwards, about an inch, or near an inch and a half in length; then, having the cions cut into lengths of four or five eyes each, prepare one to fit the ſtock, as above, by cutting it alſo a little ſloping, ſo as to exactly fit the cut part of the ſtock, as if cut from the ſame place, that the rinds of both may join in every part; then cut a ſlit or tongue about half an inch in length upwards in the cion, and cut a ſlit the ſame length downwards, in the ſtock, to receive the ſaid tongue; in that manner fix the graft in the ſtock, taking care that the ſap or rind of both may meet, or join as exact as poſſible in every part. Having thus fixed the graft, let it be immediately tied with a ſtring of ſoft baſs, bringing it in a neat manner ſeveral times round the graft and ſtocks, taking care to preſerve the graft in its due poſition; and let the bandage be neatly tied, and immediately cover the place with ſome grafting clay, obſerving to bring the clay near an inch above the top of the ſtock, and a little lower than the bottom part of the graft, leaving a due thickneſs on every ſide of the graft and ſtock, making it in a roundiſh oval form, and take care to cloſe it well in every part that no wet, wind, or ſun can enter; to prevent which is the whole intention of the clay, for without that precaution, the operation would prove fruitleſs; and in this manner proceed with the reſt. In performing the operation of whip-grafting, ſome grafters firſt cut and prepare the cion, and then cut and fit the ſtock to that; but it is not material which, provided it be done in an exact and ſomewhat expeditious manner.

Next it muſt be noted, that the grafts muſt be now and then examined, to ſee if the clay any where falls off, or cracks: if it does it muſt be renewed with freſh clay. By the laſt week in May, or firſt week in June, the grafts and ſtocks will be well united, and then take off the clay, and looſen the bandages.

Cleft Grafting.—The next general method of grafting is that by clefting the ſtock, commonly called cleft or ſlit grafting; becauſe the ſtock is cleft, and the graft put into the cleft part; and is performed in the following manner:

The proper ſized ſtocks on which this kind of grafting is performed, are generally about an inch, or an inch and a half, and even two inches, or more, in diameter. Firſt, with a ſtrong knife or ſmall ſaw cut off the head of your ſtock, and pare it very ſmooth; this done, fix upon a ſmooth part of the ſtock, juſt below where headed, to place your graft; and on the oppoſite ſide to that, cut away part of the ſtock, about an inch and a half, in a ſloping manner upwards, ſo as the crown of the ſtock may not be more than about half an inch broad. This done, prepare your graft, or cion, which is done in this manner: obſerve to cut your grafts into due lengths, leaving four or five eyes to each: then take your ſharpeſt knife, and pare away the bark and ſome of the wood at the lower end of the graft in a ſloping manner, about an inch and a half or near two inches in length; and then cut the other ſide in the ſame form, making it to have a wedge-like ſhape; but let one ſide of it, which is to be placed outwards in the ſtock, be left near double the thickneſs of the other ſide. The graft being prepared, take your ſtrong knife, and place it on the middle of the ſtock, croſs-ways the top of the ſloped part, and with your mallet ſtrike the knife to the ſtock, obſerving to cleave it no farther than what is neceſſary to admit the graft readily; then place the grafting chiſſel, or ſome inſtrument, a little way into the cleft, at the ſloped part of the ſtock, to keep it open for the reception of the graft, which then directly introduce into the cleft on the uncut or upright ſide of the ſtock, at the back of the ſlope, inſerting it with great exactneſs, as far as it is cut, with the thickeſt edge outwards, and ſo that the rind may meet exactly every way with the rind of the ſtock. The graft being placed, then remove the grafting chiſſel, taking care not to diſplace the graft; this done, let it be tied and well clayed in the manner directed as above, in the work of whip or tongue grafting. Or, if in this cleft-grafting, you chooſe to put in two grafts, it may be performed on large ſtocks, and which muſt be twice cleft, and the clefts muſt not be acroſs, but parallel to each other, and ſo fix the grafts in the ſtock, obſerving to bind and clay them as above. This kind of grafting may likewiſe be performed on the branches of trees that already bear fruit, if you deſire to change the ſorts. The grafts will be united with the ſtocks by the laſt week in May, or the beginning of June, and then take off the clay, and looſen the bandages, and apply freſh clay at the top of the ſtock.

Crown-grafting.—The third kind of grafting, is known by the name of Crown-grafting. This way of grafting is commonly practiſed upon ſuch ſtocks as are too large and ſtubborn to cleave, and is often performed upon the branches of apple and large pear-trees, &c. that already bear fruit, when it is intended to change the ſorts, or to renew the tree with freſh bearing wood. The manner of doing this ſort of grafting is as follows: Firſt, cut off the head of the tree or ſtock level, or of any particular branch of a tree, which you intend to graft, and pare the top perfectly ſmooth, then prepare your grafts, which is done by cutting one ſide flat and a little ſloping about two inches in length, making a kind of ſhoulder at top of the cut, to reſt on the head of the ſtock; and pare off only a little of the bark towards each edge of the other ſide of the graft; then raiſe the bark of the ſtock, firſt by ſlitting it downwards, and then having a ſmall wedge of hard wood, or rather iron, one ſide of it formed ſomewhat roundiſh, the other flat; let this inſtrument be driven down gently between the bark and wood of the ſtock or branch, the flat ſide towards the wood, driving it far enough to make room for the graft; then drawing out the wedge, ſlip down the graft, placing the cut or ſloped ſide towards the wood, thruſting it down as far as cut, reſting the ſhoulder thereof upon the top of the ſtock; and in this manner you may put four, five or ſix grafts, or as many as may ſeem convenient upon each ſtock or branch, and bind them round with ſtrong baſs. When the grafts are all thus fixed, you muſt then immediately apply a good quantity of well-wrought clay, bringing it cloſe about the ſtock and grafts, obſerving to raiſe it at leaſt an inch above the top of the ſtock in a rounding manner, ſo as to throw the wet quickly off, and prevent its lodging or getting into the work, which would ruin all. Thoſe trees which are grafted this way, will take, and ſhoot very free; but there is, for the firſt year or two after grafting an inconvenience attending them, and that is the grafts being liable to be blown out of the ſtock by violent winds; but this muſt be remedied by tying two or three ſticks to the body of the ſtock, or branch that is grafted, and the grafts tied to the ſticks. The beſt time for performing this kind of grafting, is in the laſt week of March, or firſt week in April; for then the ſap will begin to be more in motion, which renders the bark of the ſtock much eaſier to be ſeparated from the wood to admit the grafts. Theſe grafts will be pretty well united with the ſtock by the end of May or beginning of June.

FEBRUARY.—*KITCHEN GARDEN.*

Cucumbers and Melons.—Where the raiſing of early cucumbers and melons was not begun laſt month, it may now be commenced the beginning or middle of this with a greater proſpect of ſucceſs; obſerving exactly the ſame method in making the ſeed hot-bed, ſowing the ſeed, and general management of the bed and plants, as directed under the head cucumbers, &c. in the kitchen garden of January.

Ridging out early Cucumbers and Melons raiſed laſt Month.—If the cucumber and melon plants which were raiſed the beginning or any time laſt month, have not ſuffered by any of the accidents that are attendant on them at this ſeaſon, they will now be arrived to a proper ſize for ridging out into a larger hot-bed, finally to remain; a new hot-bed for one or more larger frames, ſhould therefore be prepared in due time for their reception. Then when the bed is in order, lay about half a buſhel or rather more, of earth juſt under in the middle of each light, raiſing each parcel of earth in a round hillock, ten or twelve inches high; then let the ſpaces between the hills, and quite to the ſides of the frame, be covered with the ſame ſort of earth, only two or three inches thick at this time, but which is by degrees to be augmented till raiſed as high as the top of the hills, as hereafter directed.

The plants which were pricked out laſt month into ſmall pots are now to be turned out of theſe pots with the ball of earth entire, in order to have the whole ball of earth adhere cloſely about the roots, to give the pots ſome water the day before they are to be planted.

Of Stopping or Pruning the above Plants.—The young plants, both cucumbers and melons, ſhould be ſtopped or pruned, if not done before, at the firſt joint, by pruning off the top of the firſt runner-bud; this will cauſe them to ſend out fruitful runners. This operation ſhould be performed when the plants have two rough leaves, and when the ſecond rough leaf is about the breadth of a ſhilling, having the runner-bud at its baſe, and the ſooner this is detached, the ſooner the plants acquire ſtrength, and put out fruitful runners. It is to be done in the following manner: You will ſee ariſing at the bottom of the ſecond rough leaf, and as it were encloſed within it, the end of the firſt runner. This appears like a ſmall bud; which bud, or runner, being the top of the plant, is now to be taken off cloſe, and may be done either with the point of a pen-knife or ſmall ſciſſars, or pinched off carefully with the finger and thumb; but which ever way you take it off, be careful not to go ſo cloſe as to wound the joint from whence it proceeds.

Having thus pruned, or ſtopped the plants at the firſt joint, they will by that means very quickly get ſtrength, as will plainly appear in a few days; and in about a week, or ten or twelve days, after being thus treated, will each bgin to ſend forth two or three runners: which runners will probably ſhew fruit at their firſt, ſecond, or third joints; for if the main or firſt runner was not to be ſtopped as above, it would perhaps run half a yard, or two feet in length, without putting out more runners to fill the frame, or without ſhewing a ſingle fruit; ſo that it is upon theſe lateral ſhoots, or runners, produced after ſtopping the plants, that the fruit is moſt likely firſt to appear in any tolerable time in the ſeaſon; but let it be alſo obſerved, that when the ſaid lateral ſhoots have three joints, and that if any of them do not then ſhew fruit at either of the joints, it will be proper to pinch off the tops of ſuch ſhoots at the third joint, which will promote their putting forth a ſupply of two or three new ſhoots, ſome or all of which will moſt likely be fruitful: and after this, let the plants take their own courſe or growth: and if the bed is well managed, and the plants are forward, they will probably produce fruit the end of this month, or beginning, or middle of next.

Forcing Aſparagus.—Hot-beds for obtaining early aſparagus may be made any time in this month. For the purpoſe of forcing aſparagus, we muſt be provided with proper plants; theſe are previouſly raiſed in the natural ground from ſeed, as hereafter directed, which being tranſplanted from the ſeed-bed into other beds in the common ground, and having two or three years growth there, they are then in a proper ſtate for forcing; obſerving, that the neceſſary quantity is from about five to ſix or ſeven hundred for a bed for a three-light frame, and ſo in proportion for two or more ſuch frames; for theſe plants in hot-beds ſhould be crowded very cloſe, in order that by having as many plants as poſſible in each frame, they may produce a proportionable ſupply of aſparagus, to recompence ſufficiently for the great trouble and expence requiſite in forcing. The hot-beds, for this purpoſe of forcing aſparagus, are made as directed for cucumbers; but it muſt be made a yard high at leaſt, and when at its proper height, level the top even and ſmooth: then directly, without putting on the frame as yet, earth it all over ſix or ſeven inches thick, for the immediate reception of the plants, for no time muſt be loſt in making the moſt of the hot-bed in forcing aſparagus; but remarking, the frame muſt not yet be put on, for the heat of the bed being very ſtrong at firſt, the framing it would make it heat too violently. The bed being made, and earthed as above, proceed to place the plants on the ſurface of the earth, previouſly raiſing at one end a ſmall ridge of earth five or ſix inches high, againſt which to place the firſt courſe of plants. This done, then place others againſt theſe in the ſame manner; and ſo continue laying them with their tops or crowns all upright, and of an equal level: then, when the whole bed is thus planted, let ſome moiſt earth be directly banked up againſt the outſide roots, all around, as high as their tops; which done, cover the crowns of the roots all over with light rich earth, about two inches thick, which concludes the work for the preſent; till the buds or young ſhoots of the aſparagus begin to appear through the earth. When the buds therefore of the aſparagus begin to appear through the ſurface of the earth, then prepare to add another portion of three or four inches depth of more mould; for there muſt be a ſufficient depth of earth for the buds to ſhoot through, that they may be of a proper length. Having applied the ſecond addition of earth, then, if you judge that all danger from burning is over, it will be proper to put on the frame. Obſerve, that if during the time the bed is without the frame, there ſhould happen exceſſive rains, or great ſnow, it is proper to cover occaſionally with mats or ſtraw, &c. But it muſt be remarked, that for the firſt week or fortnight after the bed is made, and the aſparagus planted, that the ſtate of its warmth ſhould be every day carefully examined: for that purpoſe, thruſt two or three long ſticks down betwixt the roots into the dung, in different parts of the bed; when upon drawing up the ſticks, once or twice a day, and feeling the lower end, you can readily judge of the degree of heat: if it is found to be ſo violent as to threaten to burn the earth and ſcorch the roots, it will in that caſe be adviſeable to bore, with a long thick ſtake, ſeveral wide holes in the dung, on each ſide of the bed, alſo in the earth juſt under the roots, to admit the air, and to let the rank ſteam and burning quality of the dung paſs off more freely; but, when the heat is become moderate, the holes muſt be cloſed again.

Continue to cover the glaſſes every night with mats or ſtraw. The bed, if made and managed as above directed, will begin to produce aſparagus abundantly in four or five weeks; and, provided the heat be kept up, will continue producing buds in great plenty for about three weeks. A bed for a three-light-frame will, for that time, produce three or four hundred buds a-week. The method of gathering the aſparagus in hot-beds, is to thruſt your finger down gently into the earth, and break the buds off cloſe to the roots, which they will readily do; but the cutting them with a knife, as practiſed in the natural ground, would, by reaſon of the buds coming up ſo very thick one under another, deſtroy as many or more than you gather. When it is intended to have a conſtant ſupply of aſparagus in the winter and ſpring ſeaſon, till that in the natural ground comes in, you ſhould make a new hot-bed every three weeks or month. A quantity of freſh plants muſt alſo be procured for every new bed; for thoſe which have been once forced in a hot-bed are not fit for any uſe afterwards, either in a hod-bed or the natural ground. The ſeaſon to begin to make hot-beds for forcing theſe plants, is according to the time you deſire to have the plants fit for uſe; for inſtance, if you deſire them at Chriſtmas, begin in the ſecond or third week in November. Such perſons as do not chooſe to raiſe the plants themſelves for forcing, or ſuch as deſire to be furniſhed with plants for that purpoſe till their own are ready, may in either caſe be furniſhed with them, at moſt of the kitchen-gardeners near great cities, but particularly thoſe near London, many of whom raiſe great quantities purpoſely for forcing.

Care of Cauliflower Plants. —Cauliflower-plants in frames ſhould have the free air every mild day, by taking the glaſſes entirely off. About the end of the month, if mild ſettled weather, you may tranſplant ſome of the ſtrongeſt plants into the place where they are to remain. Plant them in a quarter of rich, well-dunged ground, thirty inches, or a yard diſtance each way. Cauliflowers under hand or bell-glaſſes, ſhould alſo be thinned out towards the end of the month, if fine weather; that is, if there are more than one or two under each glaſs, let all above that number be taken away. Obſerve to take up the weakeſt, and let the ſtrongeſt remain, and draw ſome earth up round their ſtems, ſtill continuing the glaſſes, and give air, by tilting one ſide. The plants which are taken up ſhould be planted in another ſpot of ground, the ſame diſtance as above.

Sow early Celery. — About the middle, or towards the latter end of the month, prepare a ſmall bed of light rich earth in a warm border, to ſow ſome upright celery ſeed, for an early crop. Break the earth very fine, and cover it with light earth, ſifted over it near a quarter of an inch deep; the ground muſt be formed into a three or four feet wide bed; trim the ſurface ſmooth. But thoſe who deſire to have the plants come in pretty forward, ſhould ſow the ſeed in a ſlight hot-bed, under a frame and lights, or hand-glaſſes; or in default of theſe, cover on nights and bad weather with mats. The plants for this ſowing come in for uſe in June and July. There ſhould not be many of theſe early ſown plants planted out, but only juſt a few to come in before the general crop; for they will ſoon pipe in the heart, and run up for ſeed. See *April* and *June*. Let it be obſerved there are two ſorts of celery; one known by the name of Italian or upright celery; the other called celeriac, or turnep-rooted celery. The firſt is that which is moſt commonly cultivated, and of which there are two varieties, viz. common upright celery with hollow ſtalks, and ſolid ſtalked celery.

Sow Turnip-rooted Radiſh.—Sow a few of the ſmall white turnip radiſh to draw for ſallads in April and May; they eat criſp, and are agreeably flavoured.

Sow Spring Spinach.--Winter ſpinach will now advance in growth: clear out all weeds, and thin the plants for uſe as wanted. Sow ſpinach about the beginning of this month, if mild weather; let ſome good ground be got ready for this ſeed, and ſow it thin and regular, and rake it in evenly. Spinach may be ſown between rows of cabbages, cauliflowers and beans, or the like, if ground be ſcarce. The ſmooth-ſeeded, round-leafed kind is the beſt to ſow now; and if deſired to have a conſtant ſupply, let the ſowings be repeated every fortnight or three weeks till Auguſt, when you may ſow for the winter crop. See *Auguſt*.

Sow Spring and Summer Lettuces. — About the beginning of this month, if the weather is mild, you may ſow ſeveral ſorts of lettuce-ſeeds, on warm borders. The white and green cos kind, and the Cilicia and cabbage lettuce, are proper ſorts to ſow now; you may alſo ſow ſome of the brown Dutch and Imperial lettuces, or any other ſorts: let the ſeeds be ſown tolerably thick, and rake them in lightly as ſoon as ſown. If the weather ſhould be cold at the beginning of the month, you may ſow cos, or other lettuce-ſeeds, in a frame, and cover them occaſionally with glaſſes or mats, on nights and ſharp weather; obſerving, that when of due ſize they are to be tranſplanted in the full ground. But, in order to have a few come in pretty forward for tranſplanting, there may be a little green and white cos ſown on a gentle hot-bed, which will be ready to tranſplant a fortnight ſooner than thoſe in the full ground. The green cos lettuce is the hardieſt, comes in ſooneſt for uſe, and is the beſt ſort to ſow early.

Tranſplant Lettuces ſown in November or December. — Lettuces which have ſtood the winter in warm borders, or in frames, ſhould, about the end of this month, if quite mild weather, be thinned out where they ſtand too cloſe: let them be thinned regularly leaving them a foot diſtance each way, for they will require ſo much room to grow to their full ſize: the plants which are drawn out, ſhould be planted in an open ſpot of rich ground, a foot aſunder; and give a little water as planted.

Sow Onions for Summer and Autumn Supply. — About the beginning or middle of this month, you may get ſome ground ready for ſowing onions and leeks: ſow the ſeed in a dry day, on the rough ſurface, moderately thick, and as regularly as poſſible: then tread them down evenly, and rake them in with regularity. Or there may be a thin ſprinkling of leek-ſeed ſown with the onions, the onions being generally at their full growth, and drawn off, in the middle of Auguſt; the leeks will then have full ſcope, and grow to a large ſize. The leeks are generally fit to tranſplant in June and July. Obſerve the directions there given. For the winter and ſpring ſupply, ſee *Auguſt*.

Tranſplant Cabbages, ſown in Auguſt. —Early ſugar-loaf cabbages, and other cabbage plants, ſhould be tranſplanted this month where they are to remain. But if they are weakly, or much cut by the froſt, do not put them out before the end of this month, or beginning or middle of March. And let ſome rotten dung be dug in. Put in the plants in rows, two feet and a half aſunder, and allow the ſame diſtance between the rows, if deſigned to ſtand to grow to full ſize for a main crop; but if intended to cut them up young, in May and June, plant them only half a yard or two feet aſunder.

Sow Cabbages and Savoys, for Autumn. —Sow ſome ſugar-loaf and other ſummer cabbages, and large autumnal kinds, about the middle or latter end of the month, for autumn and winter uſe. Theſe will ſucceed though ſown in Auguſt, for they will be fit to cut in July, Auguſt, and September, &c. But if the winter has been ſevere, and deſtroyed many of the plants which were ſown laſt Auguſt; to ſtand the winter for an early crop, it will, in that caſe, be proper to ſow ſome of the early ſeed as ſoon in the month as the weather will permit; and, if a few is forwarded by ſowing them in a ſlight hot-bed, it would be a great advantage. Sow alſo ſome red cabbages for next winter's ſupply. Savoy-ſeed may be ſown, for the firſt time, about the middle or latter end of this month. Thoſe which are now ſown will be ready in September, and they will be finally cabbaged by October, and will continue in good perfection all November and December, &c. See *April* and *May*.

Sow Cauliflower-Seed, to ſucceed the Early Crop. — Sow cauliflower-ſeed the beginning of this month, to raiſe ſome plants to ſucceed the early crops ſown in Auguſt; but in order to bring the plants up ſoon, and to forward them twelve days or a fortnight in the growth, it will be proper to ſow theſe in a ſlight hot-bed. Sow the ſeed on the ſurface, cover it with light earth, about a quarter of an inch thick, and then put on the glaſs. But where there is not the convenience of a frame for the above bed, you may cover it on nights, and in bad weather, with mats, fixing hoops, long ſticks, or poles, arch-ways acroſs, and over theſe draw the mats. Sprinkle them with water frequently, if moderate ſhowers of rain do not fall: the cauliflowers will be fit to cut in Auguſt: ſee *April* and *May*.

Sow Beets. — This is now the time to begin to ſow the different ſorts of beet; the red beet for its large root; and the green and white ſorts for their leaves in ſoups, ſtewing, &c. let drills be drawn with an hoe, about an inch deep, and ten or twelve inches aſunder: ſow the ſeed therein thinly, and earth it over an inch thick, and let the lines be a foot aſunder.

Earth up Beans and Peas. — Beans and peas which are up, and advanced from two or three to five or ſix inches high, ſhould have earth drawn up to their ſtems, which will ſtrengthen them, and protect them from froſt. Let this be done in a mild dry day.

Sow Coriander and Chervil.—Coriander and chervil for ſoups and ſallads, &c. may be ſown any time this month, when the weather is open. Draw ſome ſhallow drills, and ſow the ſeeds therein thinly, and cover them rather more than a quarter of an inch with mold, eſpecially the coriander ſeed. Theſe plants are always to remain where ſowed; and as they ſoon fly up to ſeed, muſt be ſowed every month, &c.

Plant Garlic, Rocambole, and Shallots. — Let the beds be four feet wide, and plant the roots length-wiſe in the beds: nine inches ſhould be allowed between the rows: the roots ſhould be planted ſix inches diſtant from each other in the row, and two or three inches deep. They may be planted either with a dibble, or in drills drawn with a hoe.

Plant Horſe-Radiſh. — It is propagated by cuttings of the root, either cut from the top an inch or two long, or ſome old roots cut into pieces of that length. The method is this; firſt procure a quantity of proper ſets, which may be either the ſmall off-ſets that ariſe from the ſides of the main roots, of which take cuttings of their tops an inch or two long; or you may uſe alſo the top or crowns of the old roots, when taken up for uſe, in cuttings of the above length; or in default of a ſufficiency of crowns or tops of either, you may divide a quantity of old knotty roots into cuttings of an inch or two long, as aforeſaid; which, if furniſhed each with two or three buds, or eyes, they will make tolerable ſets: but give preference to cuttings of the crowns or tops, if enough can be produced; obſerving, that when intended to make a freſh plantation, you ſhould, during winter, &c. when you take the plants up for uſe, reſerve all the beſt off-ſets for planting; alſo the crowns of the main roots; but this latter is only practicable in private gardens; for where the large roots are deſigned for ſale, their tops muſt not be taken off, which would render them unſaleable in market; therefore the market gardeners always reſerve the ſtrongeſt off-ſets ariſing either from the bottom, or emitted from the ſide of the main root; when you plant them make the holes ſix inches aſunder, dropping, as you go on, one ſet or cutting in each hole, with the crown, &c. upright, taking care to fill or cloſe the holes up properly with the earth, and let the rows be two feet aſunder. They muſt be kept clean from weeds about a month or ſix weeks; after which the leaves will cover the ground, and prevent the growth of weeds.

All the ſtools, or bottoms of the roots, muſt be left in the ground undiſturbed; for theſe yield a ſupply of fine roots the ſucceeding year; and when the roots are then dug up, the old ſtools ſtill remaining produce another ſupply the year after; and thus, if permitted to ſtand, they continue, as often as the produce is gathered, to furniſh a freſh ſupply the ſucceeding ſeaſon: and in that manner continue producing a full crop of fine roots for many years. But care muſt be taken when digging up the roots, always to clear the old ſtool from all ſtraggling or ſmall roots whatever; and, in the ſummer ſeaſon, to draw up all ſmall plants riſing between the rows.

Sow early Turneps for Spring and Summer. — Sow a little early Dutch turnep-ſeed about the middle or latter end of the month, in a warm-lying open ſpot of light ground; but as theſe early ſowed plants will ſoon run to feed before they attain any tolerable ſize, you ſhould ſow only a ſmall quantity at this time to come in early. You may continue to ſow turneps every month till July or Auguſt. See *July*.

Sow Scorzonera, Salſafy, and Hamburgh Parſley, to ſupply the Table for Summer and Autumn. — The latter end of this month you may ſow ſcorzonera, ſalſafy, and Hamburgh parſley. Theſe plants are in ſome families, much eſteemed for their roots, which are the only parts that are eaten. The roots run pretty deep in the ground, in the manner of carrots and parſneps, and are boiled and eaten either alone or with meat, like young carrots, &c. Theſe are fit for uſe from July till March. Sow the ſeed thin and even, on ſeparate beds, either in ſhallow drills ſix or eight inches diſtance, and earthed over half an inch, or ſowed on the rough ſurface, and rake them in equally; they are all to remain where ſowed, and the plants ſhould be thinned in May or June, to ſix inches diſtance.

MARCH. — *FRUIT GARDEN.*

Prune Fig-Trees. — Prune fig-trees, this being the beſt time of the year for performing that work. Some prune figs the latter end of autumn, but that is wrong; the young bearing ſhoots being tender, many of them are liable to be killed by the froſt in ſevere winters; therefore, if they were to be pruned in autumn, and no more ſhoots left than what would juſt furniſh the wall, and ſhould a ſevere froſt afterwards deſtroy many of the ſhoots, you have then no reſource left for ſhoots to ſupply theſe vacancies. The beſt way is to let theſe trees remain unpruned till this ſeaſon, leaving the whole ſupply of young ſhoots till this time; and if ſevere froſts ſhould happen in winter, there will be a chance, out of the whole, to find enough that have eſcaped the froſt, to lay in to furniſh the wall. In pruning fig-trees, obſerve, that as they bear only on the young wood you muſt leave a ſufficient ſupply of the laſt ſummer's ſhoots from the bottom to the extremity, in every part where poſſible, and prune out the ill-placed and ſuperfluous ſhoots with part of the old bearers and naked old wood, to have proper room to train the proper ſhoots, ſo as the tree may be equally furniſhed with bearers, at moderate diſtances, for theſe young ſhoots bear the figs the enſuing ſeaſon; fig-trees always producing their fruit on the one year old wood only. Take care always, in particular, to train in every year ſome young ſhoots, at or near the bottom, that there may be a ſupply of young branches coming up regularly one after another, to ſupply the places of long old naked branches, which will occur every ſeaſon in ſome part of the tree; for ſuch long-extended naked old branches or others not furniſhed properly with young wood ſhould now be cut out, that there may be ſufficient room to train the bearing branches regularly, and at proper diſtances. The young branches of fig-trees muſt not be ſhortened or topped, but leave each at full length; for if they were to be ſhortened, it would not only cut away the part where fruit would have appeared, but alſo occaſion them to run much to wood, and thereby never produce half a crop of fruit, ſo only cut off caſual dead ends. The tree being pruned, let every branch be immediately nailed ſtraight and cloſe to the wall, at equal diſtances, ſeven or eight inches from each other, or thereabout.

Preſerving the Bloſſoms and young Fruit of Wall-Trees. — When apricot, peach, and nectarine-trees are in bloom, ſome of the choice kinds ſhould be defended from froſt, if it ſhould happen at that time, by covering the trees with mats, &c. The mats for this purpoſe ſhould be of the largeſt ſize; one end of them ſhould be faſtened with nails or hooks, to the top of the wall, and let them hang down over the trees. The lower end of the mat ſhould alſo be faſtened down, to prevent their being blown to and fro by the wind, which would beat the bloſſoms off. When the weather is mild, the mats ſhould be taken off; for it is only in ſharp froſts that the bloſſom requires to be thus ſheltered. Or to preſerve the bloſſoms and young fruit, you may occaſionally ſtick the trees with the cuttings of the ſhoots or ſmall branches of laurel, yew, fir, and ſome other hardy evergreens, that are furniſhed with leaves, and obſerving to ſtick them between the branches, in ſuch a manner as to ſhelter all thoſe which are in bloſſom; and permitted to remain conſtantly, till the fruit is fairly ſet, as big as large peas. Or in default of evergreens, ſtick the trees, in time of their bloom, with branches of dried fern, which has a good effect in ſheltering the tender bloſſom.

Propagate Vines. — Plant cuttings of vines the beginning or middle of this month, by which means you may propagate any ſort you deſire, for the cuttings will take root freely. The cuttings muſt be ſhoots of the laſt year, which if cut from the trees laſt month, or the beginning of this, it will be the more eligible; ſhortening them to twelve inches in length, or each to about three joints, and let each cutting have about an inch, or ſo, of the former year's wood at its bottom. Though this is not abſolutely neceſſary, as they will ſucceed without old wood. They may be planted either in nurſery-rows, or in the places where they are finally to remain, either againſt walls, eſpaliers, or elſewhere; obſerve, to plant them ſomewhat ſlanting, and ſo deep that only one eye may appear above ground, which ſhould be cloſe to the ſurface. Vines are alſo propagated by layers, obſerving to lay the young ſhoots, or occaſionally with part of the branch they proceed from, laying them four or five inches deep in the earth, leaving three or four eyes of the ſhoot out of the ground, ſhortening the top accordingly, if too long.

MARCH. — *KITCHEN GARDEN.*

Care of early Cucumbers and Melons. — Examine the ſtate of the cucumber and melon hot-beds, and ſee if they are of a proper degree of heat, ſo as to preſerve the plants in a ſtate of free growth. Refreſh them now and then with water; let this be given very moderately, and in a mild ſunny day; the beſt time for doing this is from ten to two o'clock.

Sow Cucumber and Melon Seed. — Sow in any new made hot-beds, the ſeeds of cucumbers and melons at the beginning, and alſo about the middle, and towards the latter end of this month, to have a ſupply of young plants in readineſs, either to plant into new beds, or to ſupply the place of ſuch plants as may fail. The ſorts of cucumbers to ſow now are: the early ſhort prickly: the long green prickly: the white prickly: the long green Turky: the long white Turky: and the Smyrna. But the firſt two ſorts are commonly cultivated for the early and general crop, the ſhort prickly being the earlieſt, and is therefore often ſown for the firſt crop in the frames; but the long green prickly is the beſt to ſow for a main crop, either for the frames or hand-glaſſes, or in the natural ground. The white prickly, and the Turky and Smyrna kinds, are not eligible for any general crop, becauſe they are very indifferent bearers; therefore you ſhould ſow only a few by way of variety; the Turky kinds often grow fifteen or ſixteen inches long, or more.

Prick at the Cauliflowers ſown in February. — Where cauliflower plants were raiſed from ſeeds ſown the laſt month, they ſhould now be pricked out into a bed of rich earth, in a warm ſituation; but where a moderate hot-bed can be obtained, it will be moſt adviſeable to prick them therein, which will forward them greatly. By pricking out the plants on a little warmth, it will bring them forward to be fit to tranſplant for good, the middle or latter end of next month, and they will produce their heads in July.

Tranſplant Cauliflowers that have ſtood the Winter. — The cauliflowers which have ſtood in frames, or on warm-borders, all winter, muſt be planted in a rich ſpot of ground. The ground ſhould be well dunged with ſome good rotten dung, and afterwards neatly dug or trenched one ſpade deep; taking care to bury the dung in a regular manner, in the bottom of the trenches. Obſerve to plant the cauliflowers in rows thirty inches aſunder, allowing them the ſame diſtance between plant and plant in the rows. Draw ſome earth to the ſtems of the cauliflower-plants, which are under hand or bell-glaſſes: it will ſtrengthen them and promote their growth. The glaſſes may ſtill be continued over the plants, but muſt be kept conſtantly raiſed, on the ſouth ſide, at leaſt a hand's breadth high, on props; or in mild days the glaſſes may be taken off, and let the plants enjoy the benefit of warm ſhowers of rain. If there are more than one or two plants under each glaſs, let them be removed the beginning of this month; for two plants at moſt, under a glaſs, is ſufficient; but if the glaſſes are ſmall, one plant under each will be enough.

Sow Bore-cole, for Autumn, Winter, and Spring.—This uſeful plant called bore-cole, otherwiſe brown-cole, is of the open cabbage tribe, and very well worth raiſing in every kitchen-garden, for the ſervice of a family. There are two ſorts, the brown and the green, they have great merit for their extreme hardineſs to endure cold, and excellence for winter and ſpring uſe. Sow it in an open ſpot of ground, and rake it in. The plants will be large enough to plant out, in about ſix weeks after the ſeed is ſown; but when they have two or three leaves, it is eligible to thin, and prick out a quantity from the ſeed-bed four inches diſtance, that the whole may obtain proper ſtrength for final planting in June.

Italian Turnep-rooted Radiſhes.—Now ſow ſome ſmall round or Italian tnrnep-rooted radiſh; there are two ſorts, the white and the red, bnt the white is preferable to ſow for the general ſupply: it eats very agreeable in April, May, and June, both alone like common radiſhes, or to ſlice into ſallads. Let the ſeed of both ſorts be ſowed ſeparately in an open ſpace of light ground, and raked in evenly. When the plants have leaves half an inch or an inch broad, thin them to five or ſix inches.

Sow Parſneps for a general Crop.—Sow parſneps the beginning of this month, for the principal crop; that is, if they were not ſown the latter end of February. A ſpot of light ground, in an open ſituation, ſhould be choſen for theſe ſeeds, for the roots thrive conſiderably beſt in ſuch a ſoil and ſituation. The ground ſhould be trenched one good ſpade deep at leaſt, or rather double dig it: be careful to break all clods, that the roots may have full liberty to run down long and ſtraight; for if the earth is not well divided or ſeparated, the roots are apt to grow both ſhort and forked.

Forking and Spring dreſſing of Aſparagus Beds.—This is now the time to begin to dreſs aſparagus beds, which is done by forking or ſlightly digging them with a three-pronged fork. This work ſhould be begun about the middle, or latter end of the month. In forking the beds, be careful to looſen every part to a moderate depth, but taking great care not to go too deep to wound the crowns of the roots. The above work of forking theſe beds is moſt neceſſary to be done every ſpring, to improve and looſen the ground, and to give free liberty for the buds to ſhoot up: alſo to give free acceſs to the ſun, air, and ſhowers of rain. The beds being forked, they muſt afterwards be raked even; obſerving that if you do not rake them immediately after they are forked, to differ it no longer than the end of this month, or firſt or ſecond week in April, for by that time the buds will begin to advance towards the ſurface.

Sowing Aſparagus Seed.—This is now the ſeaſon to ſow aſparagus ſeed, to raiſe plants to make new plantations as above, or to raiſe plants for forcing in hot-beds. This ſeed ſhould be ſown in the beginning or middle of the month, on beds four feet wide of rich earth. Sow it broad-caſt on the ſurface, then tread it in, and caſt ſome of the earth out of the alleys evenly over the bed, and then rake them ſmooth. The plants will come up in a month or ſix weeks, when they muſt be kept very clean from weeds by a careful hand-weeding at different times in the ſummer. If the weather be very dry when the plants firſt come up, it will be proper to refreſh them now and then with water, which will forward them in their growth. They will be fit to plant out for good next ſpring in March. See the next Article.

Plant out Aſparagus into Beds.—New plantations of Aſparagus may now be made, this being the proper ſeaſon to remove theſe plants; but it may be done any time in the month, when the weather is mild. In making plantations of theſe plants, one great article to be conſidered is, to make choice of a proper ſoil; chooſe the beſt the garden affords; it muſt not be wet, nor too ſtrong or ſtubborn, but ſuch as is moderately light and pliable, and in a ſituation that enjoys the full ſun. The ground where you intend to make new aſparagus beds, ſhould be regularly trenched and a large quantity of good rotten dung buried equally in each trench, at leaſt twelve or fifteen inches below the ſurface of the dug ground. The ground being dug and laid level, divide it into beds four feet and a half wide, with alleys too feet wide between bed and bed. Four rows of aſparagus are to be planted in each bed, and ten or twelve inches diſtance to be allowed between plant and plant in the row, and let the outſide rows of each bed be nine inches from the edge. Next, let it be obſerved, that the plants for this plantation conſiſt now entirely of roots, no top; they muſt not be more than two years old; but moſt good gardeners prefer thoſe that are only one year, which are what I would chuſe to plant; as from experience I have found they generally take root much freer, and ſucceed every way better than two years old plants. If you chooſe to raiſe the plants yourſelf, it is done by ſowing the ſeed any time this month in a bed of rich earth; ſee the preceding Article; and they will be proper for planting out next ſpring. In planting theſe plants, obſerve that the crown of the plants may alſo ſtand upright, and two or three inches below the ſurface of the ground; at the ſame time drawing a little earth up againſt them with the hand as you place them, juſt to fix the plants in their due poſition, till the row is planted; then when one row is thus planted, immediately, with a rake, draw the earth into the drill over the plants, and then proceed to open another drill, or trench, as before directed, till the whole is planted. When they are all planted, let the ſurface of the beds be raked ſmooth, and clear them from ſtones.

The aſparagus being planted, the next care is, when the plants come up, which will be about the end of next month, to keep them clean from weeds, which muſt be well attended to, during the ſummer ſeaſon. For the farther management, ſee the work of *October*. Let it next be obſerved, that it will be three years from the time of planting before the aſparagus plants produce buds large enough to cut for uſe; though ſometimes a few of the largeſt buds may be cut the ſecond ſpring after planting; but I ſhould adviſe to let it be the third or fourth year before you make a general cutting. A plantation of aſparagus, if the beds are properly dreſſed every year, as directed in the ſpring and autumn months, will continue to produce good buds ten or twelve years. In making new plantations of aſparagus, it is the cuſtom of ſome gardeners, inſtead of putting in young plants, as above directed, to ſow the ſeed at once in the beds, where the plants are to remain; and it is not a bad way; for by that practice the plants are not diſturbed by a removal, and conſequently cannot fail of producing a regular crop. But it muſt be obſerved, that if two pieces of ground are to be laid down the ſame year in aſparagus, and ſuppoſe one piece to be planted with young plants, the other ſowed with ſeed, that piece which was planted will be ready to cut a year before that ſowed with ſeed. A plantation of aſparagus thus raiſed, will produce buds fit to cut the fourth ſpring after ſowing, but will be very large and fine the fifth year. As the method of cutting aſparagus may not be familiar to every one, I ſhall here explain it. You ſhould be provided with a ſtraight narrow, taper knife, whoſe blade is about eight or nine inches long, and about an inch and a half broad at the haft, narrowing to about half an inch at the point which ſhould be rounded off from the back, and made ſomewhat blunt, and the edge ſhould be made full of ſmall teeth like a ſaw; then obſerving, when the buds are from about two to three or four inches high, they ſhould be then cut, obſerving to ſlip the knife down cloſe to each bud, and cut it off ſlantingly about three or four inches within the ground, taking great care not to wound or break off any young buds coming up near it from the ſame root, for their are always ſeveral buds in different ſtages of growth, advancing at the ſame time from the ſame root. When you plant out aſparagus for forcing, ſee that article in *February*.

Spring-dreſſing of Artichokes, planted laſt March.—Make a general dreſſing of artichokes the beginning or middle of this month. Where the ground has been trenched up, and laid over theſe plants laſt winter, to protect them from froſts, let it now be levelled down, eſpecially if the plants have began to ſhoot tolerably ſtrong, otherwiſe defer it till next month; obſerving as you proceed in levelling down, to dig and looſen all the ground about the plants; at the ſame time examine the number of ſhoots or ſuckers ariſing on each ſtool or root, ſelecting two or three of the ſtrongeſt on every ſtool to remain, and all above that number to be ſlipped off cloſe with your hand; obſerving, in performing this work, to open the earth deep enough about each ſtock or root, that you may readily get to ſlip the ſuperabundant ſhoots off clean from the place from whence they ariſe; cloſe the earth in again about the root, and alſo about the young plants, preſſing it cloſe about them with your hand. The ſhoots which are ſlipped off, will do to make freſh plantations, where wanted; for artichokes are increaſed by planting the young ſhoots, and by no other method; and this is the ſeaſon to do it. ſee the next Article.

Planting Artichokes.—Where a plantation of artichokes are intended, let them be planted as ſoon in the month as you can procure good plants: obſerving that thoſe ſlips or ſuckers ſlipped off in ſpring-dreſſing the old plants as above directed, are the proper ſets for this purpoſe. There are two ſorts, the large globe artichoke, and the French or green oval artichoke; but the former is greatly preferable to plant for the general ſupply, the heads being conſiderably larger, and the eatable parts more thick and fleſhy. Plant the ſets ſingly with a dibble, in rows a yard and a half aſunder, and not leſs than two feet, nor more than a yard diſtant from one another in the row. Give them ſome water immediately after they are planted, to ſettle the earth properly about the plants, they will yield good artichokes the following autumn. But it is proper to obſerve, that you may ſow a thin crop of onions, lettuce, radiſhes or ſpinach, the firſt year between the rows of the artichokes. A plantation of artichokes will continue to produce good heads five or ſix years, and ſometimes longer; but it muſt be obſerved, that if required to have a ſucceſſion of theſe fruit, for four or five months in the ſummer, ſhould make a new plantation every ſpring; for the old ſtocks which have been planted a year or two, produce heads in June or July; and thoſe planted now, produce heads in Auguſt, September and October. See *Auguſt* and *November*.

Jeruſalem Artichokes.—Plant Jeruſalem artichokes where required. Theſe roots will thrive in almoſt any ſoil, and multiply ſo exceedingly, that it is not eaſy to clear the ground of them again, for the leaſt bit will grow. The root, the eatable part of the plant, being large fleſhy tubers, bearing ſome reſemblance to a potatoe, but of a more irregular form, and taſte ſomewhat like the bottom of an artichoke, (hence probably the name) are in perfection in autumn and all the winter, and are very good and wholeſome to boil and eat with butter, &c. Let them be planted in rows a yard aſunder, four or five inches deep, and eighteen inches, or two feet diſtant in the rows. Obſerve the ſame method in preparing the ſets and planting them, as directed for potatoes.

Sow Peas to ſucceed thoſe ſown in January. —Where a conſtant ſupply of peas are required, there ſhould be ſome ſown at leaſt every fortnight, till the month of July. The marrowfat and Spaniſh morottos, being of the large kinds, are both very fine eating peas and great bearers, and are very proper kinds to ſow at this ſeaſon; likewiſe the rouncival is a fine large pea for a late crop; but any other of the large kind of peas may be ſown any time this month. The hotſpurs, or any of the ſmaller kinds of peas, are alſo proper to be ſowed now, if required: for moſt ſorts will ſucceed if ſown any time in this month. Earthing up ſhould always be performed, for the firſt time, when the plants are about three or four inches high, and repeat this in a month's time, always taking care to keep the roots well covered.

Sow Small Salading. —Small ſallading, ſuch as creſſes, muſtard, radiſh, rape, and turnip, ſhould, when a conſtant ſupply is wanted, be ſown once a week at leaſt, in a warm border, obſerving to draw ſome flat ſhallow drills, three inches aſunder; ſow the ſeeds therein, each ſort ſeparate, and cover them lightly with fine earth. When the plants begin to come up, and if the earth cake, ſo as they cannot riſe freely, let the ſurface be lightly whiſked with the hand, or the end of the birch broom, or with a light rake. If theſe young herbs are attacked with a hoar froſt appearing on them in the morning, let them be watered to waſh it off before the ſun comes on them, which will prevent their turning black and ſpoiling. Small ſallad may be produced all the ſpring and ſummer months, by following the above directions, and alſo all autumn and winter months, by obſerving the rules of November. See *November.*

Sow and plant various Sorts of Pot and Medical Herbs. —The ſeeds of dill, fennel, borage, burnet, buglos, ſorrel, marygolds, orach and clary, together with the ſeeds of all other herbs of the like kinds, may be ſowed any time in this month, in a bed or border of common earth, and rake them in; moſt of which may remain where ſowed, if the plants are properly thinned; or ſome, as burnet, ſorrel, fennel, clary, marygolds, borage, may be planted out in beds a foot aſunder, in May, June, and July. Sow hyſſop, thyme, ſage, ſavory, and ſweet-marjorum, any time in this month; you may alſo plant them from ſlips and cuttings. Theſe ſlips or cuttings ſhould be of the laſt year's ſhoots, about five, ſix or ſeven inches long; obſerving to ſlip or cut them off cloſe to the place from whence they ariſe; but there are ſometimes off-ſet ſhoots ariſing from the bottom of the old plants that are often furniſhed with roots; which ſhould alſo be particularly choſen. Plant ſlips of baum, burnet, terragon, tanſey, pennyroyal, feverfew, and chamomile. In taking off the ſlips of theſe plants, be careful to preſerve ſome root to each; plant them nine or ten inches diſtance from each other, in beds of rich earth. Plant ſlips or cuttings of roſemary, rue, wormwood, and lavender, ſix inches apart; they will take root freely, by obſerving to water them in dry weather; they may be tranſplanted into a more open ſituation about Michaelmas, when they will be well rooted.

Plant Mint. —This is now a good time to plant mint. It is propagated either by parting the roots, or by ſlips of the young ſpring plants taken up with root fibres at the bottom; alſo by cuttings of the young ſtalks next month and May, &c, but at this ſeaſon the increaſing it by ſlips, or parting the roots, is moſt generally practiſed, and the method is this. In the third or fourth week in this month, have recourſe to ſuch old beds of mint as are well ſtocked with young ſpring plants, and there ſlip and draw up a due quantity of the beſt ſhoots properly rooted; draw them up gently, and with the help of your knife at times to raiſe or ſeparate them; every plant will riſe with tolerable good roots. Having procured the plants, let them be planted in rows about ſix inches aſunder, and five or ſix inches diſtant in the rows, and let them have immediately a tolerable watering, to ſettle the earth cloſe about the roots. Obſerve that all the ſorts of mint, ſuch as ſpearmint, pepper-mint, orange-mint, &c. may all be propagated by the above methods.

Sow Capſicums. —The ſeed-pods of theſe plants being of a hot ſpicy quality, are much eſteemed for pickling: the large podded kinds are beſt. They are tender plants, and the ſeeds require to be ſowed in a hot bed about the beginning, middle, or towards the latter end of this month: and when the plants appear, let them have a large portion of free air, and water them frequently. In the middle or latter end of May they will be fit to tranſplant, which muſt be into beds of rich earth in the common ground.

Sow Love Apples. —About the middle of this month is the time to ſow ſome tomato, or love apple ſeed; the fruit or apples of theſe plants are, in ſome families, much uſed in ſoups, and are alſo often uſed to pickle, both when they are green, and when ripe. The fruit, when ripe, is of a beautiful red colour. The plants are tender; and the ſeed muſt be ſowed in a ſlight hot bed, treating the plants as directed above for capſicums.

Plant Roſemary, Rue, Wormwood, Lavender, &c. —Plant ſlips or cuttings of roſemary, rue, wormwood and lavender, ſix inches apart; they will take root freely, by obſerving to water them in dry weather; they may be tranſplanted in a more open ſituation about Michaelmas, when they will be well rooted. Put each ſlip or cutting about two parts out of three into the ground. Or, if any off-ſet ſhoots or ſuckers riſe immediately from or near the roots of the old plants, theſe are particularly eligible for planting.

Plant Potatoes. —They may be planted any time this month, but about the middle of the month is a proper time to begin that work. In planting potatoes, be careful to procure ſome good ſets; theſe are to be prepared for planting by cutting each root into two, three or more pieces, minding particularly that each piece be furniſhed with at leaſt one or two eyes or buds, which is ſufficient. Being thus prepared, they are to be planted in rows not leſs than eighteen inches diſtance, but will be more eligible if two or three feet aſunder, and to be ſet twelve or fifteen inches diſtant in the row, and four or five deep. To plant them with dibbles, have the dibbles thick and blunt ended; or thoſe who plant large quantities in fields have dibbles about three feet long, with a croſs handle at top, to take hold on with both hands, and the lower end ſhod with iron, having a foot or ſhoulder of iron fixed at about five or ſix inches from the bottom, to put your foot upon to help to thruſt it into the ground, thruſting it always as far in the ground as the ſhoulder, by which means the holes are made all an exact depth. For large quantities in fields, one perſon may be employed in making the holes, and another to follow after to drop in the potatoe-ſets, which work of dropping them may be performed by women, or girls, or boys. See *November.*

Plant out Lettuce ſown in February laſt. —Thin and tranſplant lettuces; the cos, Cilicia, and all the ſorts of cabbage, and brown Dutch kinds, &c. which were ſown laſt month, will now all want to be thinned to a foot diſtance, and a quantity tranſplanted. For planting lettuces chooſe for them a ſpot of the richeſt ground; dig it neatly, and let the ſurface be raked even; then put in the plants by line: ſet them the diſtance of twelve or fifteen inches from one another at leaſt. Water them as ſoon as planted; and, at times, till they have all taken root.

Tranſplant Lettuces, that have ſtood the Winter. —Tranſplant cos, and Cilicia lettuce, or any other ſorts that require it. Chooſe a ſpot of good ground for theſe plants, and if moderately dunged, it will prove beneficial to their growth: dig the ground evenly one ſpade deep, and rake the ſurface ſmooth, then plant the lettuces about ten or twelve inches diſtant each way; water them immediately, and repeat it occaſionally in dry weather, till they have taken good root.

APRIL.—*FRUIT GARDEN.*

Dreſſing Strawberries. —Dreſs the ſtrawberry beds in the beginning of this month, if they were not done in the former month; the plants will now begin to puſh apace, and the ſooner this is done the better. Clear the bed from weeds, and the plants from ſtrings, and other litter; and if the main plants are crowded with young ones from the laſt year's runners, let them be thinned accordingly; for it is the beſt method to keep theſe plants in ſingle bunches, as it were, and clear of each other, ſo that there may be room to dig round them with a narrow ſpade or a trowel. The beds being cleared from litter, looſen the earth between the plants; and if you add a little freſh earth from the alleys, &c. to the beds, it will ſtrengthen the plants, and they will flower ſtrong, and produce large fruit. Strawberries may now be planted where required. A farther ſupply of pots of bearing ſtrawberry-plants may ſtill be placed in hot bed and hot houſes, &c. to produce a ſucceſſion of early ſtrawberries to ſucceed thoſe of the former months, and to afford a ſupply of ripe fruit till thoſe in the open ground ripen in June.

Examine new grafted Trees. —New grafted trees ſhould now be often looked over, to ſee if the clay keeps cloſe about the grafts; it being apt to crack, and ſometimes fall off. Where you find it any way defective, ſo as to admit the air and wet to the graft, let the old clay be taken off, and add ſome new in its ſtead. All thoſe ſhoots which riſe from the ſtock, below the graft, muſt be taken off conſtantly as they are produced; theſe, if permitted to remain, would rob the gtaft of nouriſhment, and prevent its ſhooting freely.

Examine new and old budded Trees for Inſects. —Look alſo over new budded trees; that is to ſay, thoſe that were budded laſt ſummer; they will now begin to ſhoot. Examine the young ſhoots, and look, with a careful eye, for inſects. If the leaves curl up, inſects are the cauſe of it: and if not prevented, will ſpoil the ſhoots in their firſt growth. Let the curling leaves be carefully picked off; it will prevent the miſchief ſpreading farther. Where ſmall iuſects annoy any of the wall-trees, let ſome means be uſed to deſtroy them, before they increaſe, and ſpread themſelves too far, for they would do conſiderable miſchief to the trees and fruit. When once theſe deſtructive ſmall vermin attack but one ſingle branch of a tree, they would, in a very ſhort time, over-run the whole if not ſtopped, and would ſpoil the young ſhoots, and deſtroy he leaves at a ſurpriſing rate; and when once the leaves of a tree are gone there is but little good to be expected from the fruit that year. Therefore, as ſoon as inſects or blights appear upon any part of the trees, it is adviſeable both to prune away ſuch part of the ſhoots, and to pull off all the worſt leaves that are infeſted with them; that is, ſuch as are ſhrivelled, or much curled up; then ſtrew ſome tobacco-duſt over all the branches and leaves; repeating it occaſionally, which will contribute conſiderably towards deſtroying and preventing the vermin from multiplying.

Watering wall-trees, &c. thus infeſted with inſects, often proves beneficial, provided it is often repeated in dry hot weather, and the water thrown againſt the trees with ſome force. For the purpoſe of watering the branches of wall-trees, there is nothing ſo uſeful and convenient as a hand-watering engine. This engine may alſo be uſed occaſionally in watering, in dry weather, the branches of eſpalier trees, and young or old ſtandard trees, where any of the branches are attacked by inſects of any ſort. Theſe engines are both uſeful and cheap. The beſt are thoſe made of tin and copper, and may be bought at moſt of the tin-ſhops, &c. from about eight or ten ſhillings to one or two guineas, &c. according to the ſize. New-planted trees, both ſtandards and dwarfs, againſt walls or eſpaliers, ſhould in very dry weather be well watered at the root about once a week: it will alſo be of great ſervice to water the branches of the new-planted trees, now and then, in dry weather.

APRIL.—*KITCHEN GARDEN*.

Management of Cucumbers and Melons.—Hot-beds for cucumbers and melons may ſtill be made, both for ſucceſſional crops to ſucceed the early ones; and if none were made in the former months, it may ſtill be done, with ſucceſs, to have early cucumbers in May and June, &c. and melons in Auguſt. Obſerve the ſame methods of making the bed, ſowing the ſeed, planting and managing the plants, as in the former months. Water the plants occaſionally; the cucumbers will require it often; that is, provided there be a good heat in the hot-bed, and the weather mild and ſunny; watering once every four or five days, or a week, will be requiſite, but let this be applied in moderate quantities.

Melons ſhould alſo be watered moderately, at times, for they will require it; but when theſe plants are about ſetting their fruit, they ſhould be watered very ſparingly at that time, as much humidity would retard its ſetting and prevent its ſwelling freely. Let decayed and damaged leaves be taken off as ſoon as they appear on the plants; either cucumbers or melons; alſo let all decayed male flowers be taken away, ſparing always a ſufficiency of the freſh bloſſoms for the office of impregnation, as below. In hot days, when the ſun is fierce, ſo as to occaſion the leaves of the melons or cucumbers to flag, it will be proper to ſhade them for two or three hours, during the greateſt heat, with a thin mat, or with a little looſe hay ſtrewed thinly over the glaſſes.

Impregnate, or ſet the young fruit of cucumbers with the farina of the male bloſſom. The flowers of cucumbers and melons are male and female, ſeparate, on the ſame plant, and the females produce the fruit; the males are often erroneouſly called falſe bloſſoms; and many perſons in conſequence of that notion, pull them off; but they are ſo far from being falſe bloom, that they are by nature deſigned to impregnate the female flowers, to render them fruitful; for the antheræ in the centre of the male bloſſom being furniſhed with a fine powder, which being diſperſed on the ſtigma in the centre of the female, the fecundation is effected, and the fruit in a day or two after will begin to ſwell, and in a fortnight will be arrived to a proper ſize for cutting; ſo that without the aſſiſtance of the male bloſſom, the female having the embryo fruit at their baſe, wither and decay; and the infant fruit turns yellow and drops off. Therefore it is of importance to preſerve a ſufficiency of the male flowers, for the purpoſe of impregnating the female; and in the early culture of cucumbers, &c. it is eligible to carry ſome of the male to the female flowers, obſerving for this purpoſe, to detach ſome new expanded male bloſſoms with the ſtalk to each, and holding the ſtalk between the finger and thumb, and pulling off the petal or flower-leaf ſurrounding the male organ; then with the remaining anthera, or central part, touch the ſtigma of the female, ſo as ſome of the farina or male powder of the anthera adheres to the ſtigma, a little of which being ſufficient to effect the impregnation.

This operation is eſſentially neceſſary to early plants that are ſhut up in frames, before the lights or glaſſes can be admitted ſufficiently open to give free acceſs to a large current of air, or flying inſects, ſuch as bees, &c. all of which aſſiſt in conveying the farina of the male bloſſom to the females; as is evident in plants expoſed to the open air. The above operation of fecundating, or, as the gardeners term it, ſetting the fruit, ſhould be performed the ſame day the flowers open; and as ſoon as they are fully expanded is the proper period. The female or fruit-bearing flowers, are readily diſtinguiſhed at ſight from the males; the former having always the germen or embryo fruit placed immediately under the baſe of the flower; or, in other words, the embryo-fruit iſſues forth with the flower-bud on its top, viſible from its firſt irruption from the ſtem of the plant; but the male bloſſom is placed immediately on the top of its foot-ſtalk, without any appearance of germen, or fruit under its baſe.

Make Ridges to plant out Cucumbers and Melons, under Bell or Hand Glaſſes.—Make hot ridges, about the middle or latter end of this month, for the cucumbers or melon plants raiſed laſt month, in order to be planted under hand or bell glaſſes. Theſe hot-beds or ridges for hand or bell-glaſſes, ſhould, at this time, be made the greateſt part above ground, not digging deep trenches, as is often practiſed, wherein to make them; for by that practice, you cannot readily line the beds quite down to the bottom when the heat declines. The making them in deep trenches in May, when but very moderate linings, or ſometimes none at all, will be required, is not improper; but at this ſeaſon do not make trenches deeper than about ſix inches. Each bed or ridge for the bell or hand-glaſſes, ſhould not be leſs than two feet and a half thick of dung, and ſhould be three or four feet wide. The beds being made as above directed, then in two, three, or four days after, when the dung will be ſettled, and the heat ariſen to the top of the bed, lay on the earth; this ſhould be laid ten inches thick on every part. Then ſet on the bell or hand-glaſſes, one over each hole or ridge, and keep them cloſe down till the dung has thoroughly warmed the earth; then proceed to put in the plants: turn them carefully out, with the ball of earth entire, and make a hole in the earth where each glaſs ſtands; place out the plants, with the ball into each hole; cloſe the earth very well about the ball, and alſo about the ſtems of the plants; give every hole a little water, and immediately put on the bell or hand glaſſes. Let two melon plants be ſet for each glaſs, but you may plant three or four cucumber plants under each: as ſoon as they are planted, let them be watered, to ſettle the earth about their roots, but let moderation be always obſerved in performing this work, eſpecially when newly planted. Shade the plants occaſionally from the ſun, when it is powerful, till they have taken good root in the new earth; but when the plants are able to bear the ſun without flagging, let them enjoy it freely. Let the glaſſes be covered every night with mats, till the end of May, or beginning or middle of June. Remember, if the plants have not been ſtopped or topped before, it muſt now done: this is to be done when the plants have two or three rough leaves; obſerving, at that time, to pinch off the top of the plant in the manner already directed.

Sowing Cucumber and Melon Seeds.—Sow the ſeeds of cucumbers and melons the beginning of this month, to raiſe ſome plants to ridge out, under hand or bell glaſſes, in May. See the directions of laſt month.

Plant early Kidney Beans.—Plant kidney beans, of the early kinds, the beginning of this month. Draw drills an inch deep, and thirty inches aſunder; drop the beans in the drills two inches apart, and draw the earth equally over them; do not cover them more than an inch deep; for, if covered too deep at this early time, they do not come up well, but riſe ſtraggling, and beſides they are very apt to rot. Theſe ſhould be planted in dry weather, for the ſeed cannot bear much wet at this early ſeaſon; it being apt to rot in the ground, if planted in rainy time. About the middle or twentieth of this month, you may plant ſome kidney beans for a principal crop. The ſpeckled dwarf kidney bean, and the Batterſea and Canterbury dwarfs, are proper kinds for this plantation, allowing two feet and a half, at leaſt, between the rows. You ſhould plant in May for a late crop, plant in July for a general crop. See *July*.

Prick out Cabbages ſown in February.—Some of the ſavoy and cabbage plants which were ſown in February, for a forward autumn crop, ſhould be thinned and pricked out into beds, to get ſtrength before they are planted out for good. Let this be done when the plants have leaves one or two inches broad: preparing beds of good earth about three feet and a half wide, in an open ſituation. Place them at four or five inches diſtance every way. Water them immediately, and repeat it occaſionally in dry weather.

Tranſplant Cabbages and Savoys which have ſtood the Winter.—Now tranſplant, if not done in March, all the cabbage plants yet remaining in their winter beds, or all that you intend planting out finally this ſpring, for the ſummer and autumnal crops; and let it be done in the beginning, or as ſoon as poſſible this month, that they may get good root before dry weather ſets in; give the plants a little water as ſoon as planted. Draw up ſome earth about the ſtems of forward cabbage plants; it will ſtrengthen them, and greatly encourage their growth.

Earth up Cauliflowers.—The early cauliflower plants under hand-glaſſes, ſhould have earth drawn up to their ſtems. This will be of great ſervice in promoting their growth; but in doing this, let care be taken that no earth is drawn into their hearts.

Sow Broccoli, for Autumn and Winter Supply.—Chooſe ſome early purple, to come in for autumn, and late purple to ſtand the winter for the general crop, and a proportionable ſupply of the white or cauliflower broccoli; ſow them in an open ſpace of light rich ground, each ſort ſeparate, and rake them in evenly; the plants will ſoon come up, and be fit to plant out in June.

Prick out Celery, ſown in February.—The young celery plants, which were ſown in February or March, for an early crop, will be fit to prick out towards the middle or latter end of this month, into a nurſery bed of rich light earth, or in a hot bed. Prepare a ſpot of rich light ground, and plant them into this, at about three inches diſtance every way; then give a moderate watering, and repeat it at times till the plants have taken freſh root. The plants ſhould remain in this bed a month or ſix weeks, to get ſtrength before they are planted out for good into the trenches in June. As theſe early ſown plants, after they become fit for uſe, will not continue long before they will run up for ſeed, there ſhould not be any large quantity of them planted out. Sow ſome celery ſeed, in the firſt or ſecond week of this month, to raiſe ſome plants for a general crop, and to ſucceed thoſe which were ſown in March.

Sow Carrots and Parſnips for Summer ſupply. — Carrots may yet be ſowed, if required; but in order to have tolerable ſized roots, in ſum reaſonable time in ſummer, let the ſeed be ſown the beginning of this month. Where, however, a ſupply of young carrots are required, it is proper to perform two different ſowings this month; the firſt ſowing ſhould be in the beginning, and the ſecond towards the latter end of the month. Parſnips may alſo ſtill be ſowed in the beginning of this month; but if ſowed later, the crop will not ſucceed.

Sow Purſlane.—Purſlane may be ſowed now, if warm dry weather, on a bed of light rich earth, in the common ground. Sow it evenly on the ſurface, and rake it in lightly. Water the bed often in dry weather, and ſhade it from the hot ſun till the plants are come up, and have got a little ſtrength. But if cold or very wet weather, ſow ſome in a warm dry border, and defended from cold, &c.

Sow Naſturtiums. — Naſturtiums are often uſed in families; their flowers and young leaves for ſallads, the flowers alſo to garniſh diſhes, and their green berries to pickle. This is now a good time to ſow them, and the ſooner in the month the better. Drills muſt be drawn for them as is practiſed for peas; the ſeeds muſt be dropped into the drills two or three inches aſunder, and be covered an inch deep with earth. When the plants are come up about ſix inches high, they ſhould have ſticks placed for them to run upon: for theſe plants are of the running or climbing kind; or for the ſake of ſupport, may ſow them near a hedge, rails or any other fence. This plant being of a moiſt cold nature, is by many people much eſteemed to uſe in ſummer ſallads.

MAY. — *FRUIT GARDEN.*

Rubbing off uſeleſs Buds and pruning of Wall Trees and Eſpaliers.

Wall trees will now, in general, begin to make ſtrong and numerous ſhoots; and they ſhould be regulated, and trained the right way, before they grow into confuſion. Apricots, peaches, and nectarines, in particular, demand this care now; and alſo plum and cherry-trees. Let all theſe trees be looked over ſome time in this month, as early as poſſible, before they advance conſiderably into diſorder in their firſt ſhoots, and cleared from all ſuch, of the new ſhoots as are uſeleſs and ill-placed; at the ſame time let all the well-placed uſeful ſhoots be retained, and when of due length, trained in cloſe and regular to the wall. In the early ſummer dreſſing of wall-trees this month, when the firſt ſhoots do not exceed one, two, or three inches long, moſt of the requiſite pruning may be performed, by rubbing off the uſeleſs ſhoots with the finger and thumb, without the uſe of a knife; but when more advanced, the knife only muſt be uſed. Apple, pear, plum, and cherry-trees, either againſt walls or eſpaliers, ſhould alſo be looked over ſome time towards the end of this month: for theſe trees ſhould alſo be diveſted of all uſeleſs and ill-growing ſhoots of the year, and the neceſſary regular ones trained in. This may be done next month if omitted in the preſent.

Thin Apricots, Peaches, Nectarines, &c. — Thin apricots, peaches, and nectarines, where they are ſet too thick upon the trees. Theſe trees, in favourable ſeaſons, will ſometimes ſet three times more fruit than their roots are capable of ſupplying with proper nouriſhment; and if the whole or too many of them were to be left, they would ſtarve one another, and the fruit, in general, be ſmall and ill-flavoured. Beſides, where there are too great a quantity of theſe ſorts of fruit permitted to remain upon the trees, the ill-conſequence does not terminate altogether in the badneſs of the fruit that year, but it extends to two or three years to come; for the too great quantity of fruit would draw the whole nouriſhment to themſelves, inſomuch that the trees would not be able to produce ſhoots capable of bearing fruit next year: and it would alſo exhauſt the trees ſo much, that they could not regain ſtrength to produce any good wood before the ſecond year after; and it would probably be the third before a tolerable crop could be expected.

Therefore, where theſe fruit are produced too thick upon the trees, let them now be reduced to a moderate quantity on each tree; and the ſooner this is done the better it will be for the trees, and alſo for the fruit that is to remain upon them. The moſt promiſing and beſt ſhaped fruit muſt be left, having ſome regard alſo to thoſe that are beſt ſituated on the branches. Each kind, according to its ſize, muſt be left at ſuch diſtances, that every one may have ſufficient room to ſwell, and grow freely to its full ſize every way, without touching another. For inſtance, ſuppoſe a tree to be in pretty good condition for ſtrength, and allowing the bearing ſhoots or branches to be of three different ſizes; that is, the ſtrong, middling, and weakly; the number of fruit to be left upon each of theſe branches are; upon the ſtronger ſhoots and branches three or four of the faireſt and beſt placed fruit; upon the middling ſhoots no more than two or three, and only one or two upon the weaker branches.

This ſhould be the method of thinning the common ſizes of theſe kinds of fruit; but the ſmall kinds may be left cloſer, and a greater number of each kind may be left upon the different branches. For inſtance, the early maſculine apricots, the nutmeg peaches, and early nectarines, being ſmall varieties of theſe kinds, there may be left upon each of the ſtrong ſhoots, about four or five of theſe fruit; and on a middle ſized ſhoot three; and ſo in proportion on the weaker ſhoots. The young fruit that are thinned off, are excellent for tarts, &c. particularly the apricots.

Deſtroy Snails.—Snails often make great havock among the choice kinds of wall-fruit, where they are not interrupted; they particularly infeſt the apricots, nectarines, and peach-trees, and will do miſchief to thoſe kinds of fruit, if not prevented. Theſe trees ſhould be often looked over early in a morning, and in an evening, and after ſhowers of rain, at which times theſe creeping vermin come forth from their holes, to feed upon the fruit, and may then be readily taken and deſtroyed: this caution ſhould be continued the two next months.

Management of Vines.—Vines now ſhoot vigorouſly, and they will produce, beſides bearing and other uſeful ſhoots, numbers that are altogether uſeleſs, which muſt now be all cleared away, and the ſooner the better. It is not every ſummer that is favourable to the ripening of grapes; but it is in every one's power to give them great aſſiſtance, by a right ordering of the vines at this early time; and where this work is executed in a timely and proper manner, the bunches of theſe fruit may be brought to be large and handſome, and much ſooner and better ripened than what is commonly done. To do this, the vines muſt now be perfectly well cleared from all ſorts of uſeleſs ſhoots of the year; and, at the ſame time, all the fruit-bearing, and other well placed uſeful ſhoots, ſhould be nailed up regularly, and cloſe to the wall; for there is a great deal of advantage attends this early dreſſing, both in affording an opportunity of performing the work with more expedition and regularity, and for the greater benefit of the trees and fruit; obſerving, that all the immediate bearing ſhoots, which now diſcover the advancing young bunches of fruit upon them, muſt be left; and ſuch other ſhoots as have ſtrength, and are very well ſituated for training in, for the purpoſe of bearing the next year, muſt alſo be left in places where they are apparently wanted, and can poſſibly be trained in. But all weak ſtraggling ſhoots, ſuch particularly as often riſe immediately from old wood, are uſeleſs, and muſt now be cleared away. After this, obſerve that all ſhoots that riſe in any part of the vines, muſt be conſtantly rubbed off according as they are produced; and by no means ſuffer thoſe ſmall ſhoots to remain, which commonly riſe from the ſides of the ſame ſummer's ſhoots that are now laid in; but let theſe be duly rubbed off as ſoon as they begin to advance. The early ſummer dreſſing of vines, in reſpect to pruning, may be effected with the finger and thumb, while the ſhoots are quite young and herbaceous; as the uſeleſs ſhoots may then, without a knife, be very expeditiouſly rubbed off cloſe to the mother wood.

Water Strawberry Plants. — The ſtrawberry plants will be in full bloſſom this month; therefore if the weather ſhould prove very dry, the beds ſhould be often watered to encourage the fruit to ſet. During the time theſe plants are in bloſſom, the beds ſhould be watered in dry weather about three times a week; and they ſhould have ſuch a watering at each time, as will reach to the roots of the plants. This is very needful work in dry weather, and it ſhould not be omitted, otherwiſe there will be but a very ſcanty crop of ſtrawberries, and theſe will be ſmall and not well reliſhed: this care of watering ſhould be continued alſo all the next month, provided the weather is dry.

Examine new-grafted Trees. — Examine the trees of all ſorts that were grafted this ſpring; when the graft and the ſtocks are well united, there is no farther occaſion for the clay. This is generally well effected by the middle or latter end of this month, at which time the clay ſhould be taken away; but let the bandages remain two or three weeks longer, or till the parts begin to ſwell; then take them off entirely.

Examine new-budded Trees. — Look alſo to new-budded trees; that is, let the trees which were budded laſt ſummer, be now often looked over, and take off all ſhoots that riſe from the ſtock, near the bud. This ſhould be conſtantly practiſed as often as any ſhoots appear; and let them be rubbed off quite cloſe; then the ſtocks having nothing to ſupply but the bud, it will certainly ſhoot more vigorouſly.

MAY. — *KITCHEN GARDEN.*

Care of Melon Plants in Frames. — Melon plants ſtill require particular care; thoſe which are under hand or bell-glaſſes, as well as thoſe in frames. The early plants in frames will now ſhew fruit plentifully, and ſome will be ſet and ſwelling; therefore in order to procure a ſufficient quantity of thoſe fruit for a full crop, the plants muſt, at this time, have all the aſſiſtance that is in the power of art to give them. One principal thing to be obſerved is, to preſerve a proper degree of heat in the beds, by occaſional linings of hot dung, while the fruit is about ſetting, and for ſome time after; for a kindly warmth is neceſſary to promote the ſwelling of the fruit after they are ſet; for it ſhould be obſerved, that although there be often very warm days in this month, yet there are often cold nights, which make it ſo neceſſary to preſerve a due heat in theſe beds; for if the weather ſhould prove cold, and at the ſame time there is but little warmth in the beds, the melons will not ſet nor ſwell kindly, but moſt of them will turn yellow and go off. The advantage of adding freſh lining to ſuch beds as are much decayed in their heat, will ſoon evidently appear in the growth of the plants and fruit. Air muſt be admitted to the plants, by raiſing the upper ends of the lights with props, gradually, one, two, or three inches, according as the power of the ſun and warmneſs of the day increaſe, and ſhut them down cloſe again about four or five in the evening, or ſooner, if the weather ſhould change cold or prove windy. About ſix or ſeven in the morning, let the mats be taken off; or when it is a warm ſunny morning, they may be uncovered as ſoon as the ſun reaches the glaſſes, for the plants ſhould not be kept too long in darkneſs, light being very eſſential to their growth. Shut down the lights immediately after watering; and, if the ſun ſhines, throw a mat over for half an hour, then take it off again. Obſerve, in watering theſe plants, to let as little as poſſible touch the fruit that are about ſetting. Where the plants advance very near the glaſſes, it will be neceſſary to raiſe the frame from about three to ſix inches; this is done by placing bricks, or ſquare pieces of wood, under each corner of the frame. According as the melons ſet, obſerve to place a piece of tile under each; for this will preſerve them from the damp of the earth of the bed.

Care of Melons and Cucumbers, under Bell and Hand Glaſſes. — When any of the melon or cucumber plants have filled the bell or hand glaſſes, the vines muſt then have liberty to run from under them: but they muſt not be truſted out before the latter end of the month, or beginning or middle of next. If therefore, about the laſt week in this month, or beginning of next, the plants have advanced conſiderably in runners to the extent of the glaſſes, they ſhould be trained out; provided however the ſeaſon is become warm, dry, and ſettled, not elſe: raiſing each glaſs upon three props, about two inches and a half high, and let the ends of the vines be trained out at regular diſtances, and peg them down; being careful to cover the ridges every night, and in all bad weather, with good mats. But when the vines of theſe plants are trained from under the hand glaſſes; it would be of great advantage to place oiled paper frames over ſome of the beds, previouſly removing the hand glaſſes; theſe frames remaining conſtantly night and day; and as they admit the light and heat of the ſun ſufficiently, they will prove moſt beneficial ſhelters. See *June*.

Cucumbers to pickle. — Sow cucumbers for pickling, &c. theſe are to be ſown in the natural ground; not however generally till the laſt week in this month. But if the ſeaſon be cold, or very wet, it would be proper to defer putting in the ſeed till the firſt week in June. Mark out the holes for the ſeed, exactly along the middle of each bed, allowing three feet and a half between hole and hole. Dig the places for the holes, breaking the earth well with the ſpade, and form them with the hand like a ſhallow baſon, about an inch and a half deep, and ten or twelve inches over; and ſow in the middle of each hole eight or ten ſeeds, covering them near half an inch deep with earth. After the ſeed is ſown, if the weather ſhould prove hot and dry, it will be proper to ſprinkle the holes with water; but this muſt be given moderately, juſt enough to moiſten the earth a little, for too much moiſture would rot the ſeed: but when the ſeed is germinated, and the young plants coming up, give water freely in dry warm weather. When the plants have been come up about a fortnight, they muſt be thinned; and leave no more than four, five, or ſix of the beſt plants in every hole. In ſowing picklers, it is the practice in cold wet ſeaſons, with many of the London gardeners, to ſow the ſeed on a ſlight hot-bed: and when the plants have been up about a week or ten days, to tranſplant them. It is adviſed to tranſplant theſe plants when quite young, in little cluſters together, therefore ſow the ſeed accordingly, that is, either with a thick blunt-ended dibble, or with your fingers contracted make holes about an inch wide, and half an inch, or near an inch deep, and about an inch and a half aſunder, dropping eight or ten ſeeds in each hole, this is called dotting them in; cover them near half an inch deep with earth. By thus ſowing the ſeed in patches, the plants will riſe in bunches; when the plants have been come up ſix, eight, or ten days, and ſhew the rough leaves in the centre, it is proper to plant them out, if the weather is ſettled; taking them up in cluſters as they grow, with the earth about their roots, and in that manner let them be planted in the places where they are to remain. This, in a bad ſeaſon, is a very good method, and worthy to be put in practice.

Sow late Celery for Winter and Spring ſupply. — Sow ſome celery ſeed about the middle of this month for a late crop, and follow the directions laid down in February. Prick it out in July, and follow the directions laid down in April, and finally tranſplant in September. (See September and November) and remember to earth up the celery ſown in February, and continue this neceſſary buſineſs every month.

Cutting Aſparagus, and care of the Beds. — Aſparagus will now be fit to cut for uſe. In cutting the buds or ſhoots of theſe plants, it ſhould be obſerved, that, when they are from about two or three to four or five, or at moſt ſix inches in height, they ſhould be gathered; but thoſe about three or four inches high are in prime order; when permitted to run much higher, the top of the bud opens, and the ſhoot does not eat ſo well as thoſe that are cut when the head is quite cloſe. When you cut them, be careful to thruſt your knife down cloſe by the ſide of the ſhoots you intend to cut, leſt you wound or deſtroy any young buds that are coming up and do not yet appear; cutting the ſhoots off ſlanting about three or four inches within the ground. See *April*. Let the beds of theſe plants be now carefully cleaned, for ſeed weeds will now riſe very thick on them.

Thin out Hamburgh Parſley, Scorzonera, and Salſafy, and alſo ſow for a Winter Crop. — The Hamburgh or large-rooted parſley, ſcorzonera, and ſalſafy, muſt now be carefully cleaned; and the plants ſhould be thinned, or hoed out, to proper diſtances, that their roots may have room to ſwell. Leave theſe plants about ſix or ſeven inches diſtance from one another. The ſeeds of ſcorzonera and ſalſafy ſhould now be ſown for the winter crop. Sow them in the firſt or ſecond week of this month. Theſe plants, when ſown early, are apt to run up for ſeed, before they are hardly fit for uſe. But thoſe that are ſown now will not run, and their roots will be in excellent order for the table by Michaelmas, and continue good till ſpring following.

Tranſplant Savoys and Cabbages, ſown in February. Tranſplant ſpring-ſowed cabbage and ſavoy plants for autumn and winter uſe. Theſe may be planted between rows of early cauliflowers, or between wide rows of garden beans, or French beans; that is, if there be no other ground at liberty. Plant them out, if poſſible, in moiſt weather, in rows two feet and a half aſunder, and about two feet diſtance in the lines; and as ſoon as they are planted, give each a little water.

Tie up the Leaves of Cabbages, that have ſtood the Winter. — The earlieſt cabbages will now be well advanced in growth, have formed tolerable full hearts, and begin to turn their inner leaves for cabbaging; they may be greatly aſſiſted and brought forward by tying their leaves together. Get ſome ſtrong baſs, or ſmall oſier twigs, and go over the plants row by row, and let ſuch of the forwardeſt, with fulleſt hearts, as have begun to turn their leaves pretty much inward, be tied: do not tie them too ſtrait, for that would occaſion the plants to rot. This will bring the plants forwarder for uſe ſooner by a week or fortnight than they would naturally be of themſelves; and they will be much whiter in the heart, and more tender to eat.

Protect Early Cauliflowers from Rain and Sun. — Look over early cauliflowers often, about the middle or latter end of the month; ſome of the plants will then begin to ſhew their flower heads in the center; and as ſoon as theſe appear, they ſhould be ſcreened from the ſun and wet, which would change the colour from a milk white to a yellow. Therefore, as ſoon as ever a flower appears, let ſome of the largeſt leaves be broke down over it. This will anſwer the double purpoſe of ſhading the head from the ſun, and defending it from wet; whereby the cauliflowers will be preſerved in their natural whiteneſs, and will be cloſe, firm, and beautiful. Theſe plants ſhould, in very dry weather, be often watered; for this will cauſe the heads to grow to a larger ſize. But previous to doing this, you muſt form the earth hollow like a baſon, round each plant, to contain the water when given to them.

Plant out Love Apples, for Soups, &c. — Theſe plants being trailers, and very luxuriant and rambling in their growth, muſt therefore be planted cloſe to a wall, pales, or eſpaliers; and when they begin to branch out, muſt be trained, and nailed to the walls or pales, in the manner of a wall tree, or may be trained to ſtrong ſtakes. Obſerve, they muſt be planted againſt a ſouth wall, or other ſouth fence; for if they were to be planted in the ſhade, the fruit would not ripen. The vacant ſpaces between wall-trees would ſuit them well.

Tranſplant Cauliflowers ſown in February. — Tranſplant, if not done laſt month, the young cauliflower plants raiſed this ſpring from ſeed. The plants are to be ſet in this compartment at two feet, or two feet and a half each way aſunder; and they muſt be watered as ſoon as they are planted. There may be ſown, if you chooſe it, on the ſame ground between the cauliflower plants, a thin crop of ſpinach.

Sow Cauliflower-ſeed for a Michaelmas Crop. — The plants that are raiſed from this ſowing will come into uſe in October, and will be in high perfection the greateſt part of November, and ſometimes longer. Theſe are what the London gardeners call the Michaelmas cauliflowers. Obſerve, the ſeed for this crop muſt not be ſowed till about the 24th of this month; at which time get ſome good ſeed of the laſt year's ſaving; ſow this moderately thick, and rake it in carefully, and ſprinkle the bed often in dry weather with water. When the plants have got two or three leaves an inch broad, they ſhould be pricked out into a nurſery-bed to attain ſtrength for final tranſplantation. See *June* and *July*.

Sow Endive, for an early Crop. — Sow endive for an early crop; principally ſome of the white, and a ſmall portion of the green. Likewiſe ſow ſome broad-leaved Batavia endive; this is the beſt ſort for ſtewing; it grows very large, and, if tied up, will cabbage well, and be very white, and eat alſo well in a ſallad: but this ſort is not hardy, for it ſoon rots in a wet autumn, and a moderate froſt will kill it. If required early, in conſtant ſucceſſion, it will be adviſeable to ſow ſome ſeed at two different times this month. But never depend on the ſowings of this month for a main crop, the plants being apt to run up ſoon to ſeed the ſame year;

however, where a few early plants are required, you may ſow a little ſeed about the beginning or middle of the month, and more towards the latter end; the plants of the firſt ſowing will not continue fit for uſe long; but the ſecond ſowing will not run ſo ſoon. But the ſeaſon for ſowing the principal autumn and winter crops, is the beginning or middle, and latter end of June, and in July. This ſeed ſhould be ſown in an open ſpot of rich earth; it muſt not be ſown thick, and take great care to rake it evenly into the ground. See *June, Auguſt,* and *September.*

Support Plants for Seed. — Support the ſtems or ſtalks of ſuch plants as were planted for feed. The onions and leeks, in particular, will now require this care; for the ſtalks of theſe plants will be run up to a good height: and if they are not ſecured in due time, the winds and heavy rains will break them down. Support likewiſe the ſtems of cabbages, ſavoys, and broccoli, which are for ſeed; having ſome ſtout ſtakes, let one or two be driven into the ground, cloſe to every plant, and the principal ſtems be tied ſecurely to them. Beſides, when the weeds are ſuffered to grow large among any ſmall crops, ſo as to mix and entangle with one another, and with the plants, it renders the work of hoeing or weeding them extremely tedious, and very troubleſome to perform.

Plant Radiſhes for Seed. — Tranſplant radiſhes for ſeed: this muſt be done when the roots are juſt in their prime: and the firſt and ſecond week in the month is the moſt proper time to do it: and if it is ſhowery weather, it will be a particular advantage. Chooſe for this purpoſe ſuch roots as are long, perfectly ſtraight, and with ſhort tops. Having alſo ſome regard to the colour of the root, that is, if it is the common red or ſhort-topped radiſh: thoſe that are of a clear pale red are in moſt eſteem, and particularly with the London gardeners, for market, as they generally eat more criſp and mild, than thoſe of a dark red colour; and when intended to ſave ſeed of the ſalmon radiſh, although theſe will be naturally of a pale red, yet to preſerve the ſorts it will be proper to plant the paleſt coloured roots. The principal reaſon why we direct radiſhes intended for ſeed to be tranſplanted is, that we can readily judge of the goodneſs of the root, take only what are of the right ſort, and reject ſuch as are not. Plant them three feet aſunder, they will ſhoot up ſtrong ſtalks, and ripen ſeed in September.

Deſtroying Weeds. — Let more than common care be now taken to deſtroy weeds among crops of every kind, and in every part throughout the ground. There is no work in the kitchen garden that requires more attention now than this: for weeds are at no time more detrimental to crops than the preſent. It ſhould therefore, be one of the principal works in this ground to deſtroy them before they grow large. For weeds, when permitted to grow large, not only exhauſt the goodneſs of the ground, and ruin the preſent crops, but are alſo a very diſagreeable ſight, and require more than double labour to clear the ground of them.

JUNE. — *FRUIT GARDEN.*

Method to fill vacant Parts of Wall-Trees with Branches. — At this ſeaſon it will be proper to obſerve, that where there are any vacant ſpaces in any kind of wall, or eſpalier-trees, it is now a moſt eligible time to prepare to furniſh them with the requiſite ſupply of wood in ſuch parts, the ſame year, by pinching or pruning ſhort ſome contiguous young ſhoots. For example, if two, three, or more branches may be wanted to fill the vacancy, and ſuppoſe there be only a young ſhoot produced in or near that place, it will, in ſuch caſe, be proper in the firſt or ſecond week of the month to ſhorten the ſaid ſhoot or ſhoots, to three, four, or five eyes, according to their ſtrength: and by this practice each ſhoot will ſend forth two or three, or perhaps four lateral ſhoots the ſame ſeaſon, to fill the vacancy. The above method of ſhortening the young ſhoots of the ſame ſeaſon may likewiſe be practiſed on young trees, to procure a ſupply of branches to form a head.

Planting Strawberries. — Where new plantations of ſtrawberries are wanted, it will, about the middle, or latter end of the month, be a proper time to provide ſome young plants for that purpoſe. Remember, however, to chooſe the young plants of the ſame year, which are formed at the joints of the runners, or ſtrings, that iſſue from the ſides of the old plants. In chooſing the plants, let them be taken from ſuch ſtrawberry beds as bear well, and produce large fruit. Chooſe a parcel of the ſtouteſt plants of the ſame ſummer's growth, as above hinted, taking them carefully up with the roots. Trim the roots a little, and cut off the ſtrings or runners from each plant; then let them be immediately planted. But it will not be ſo proper to plant them now into the beds or places where they are to remain; but rather plant them into a nurſery-bed, in a ſhady ſituation; a ſhady border will be a proper place: there put in the plants about four or five inches aſunder; and, as ſoon as planted, give a gentle watering to ſettle the earth to their roots. There let them remain till September, or October; by which time they will be ſtrong, and in fine order to tranſplant, and are then to be planted out for good. The above method of procuring ſtrawberry plants at this ſeaſon is not commonly practiſed; but it is much the beſt way, for the plants will be much ſtronger and finer by September, than any that can be procured at that time from the old beds, and will bear ſooner. Or for immediate bearers you may, any time in this month, plant out ſome of the young runner plants of the alpine, or prolific monthly ſtrawberry, they will bear fruit the ſame year: that is, they will bear in Auguſt, September, and October; and, in mild ſeaſons, this ſort of ſtrawberry will bear till near Chriſtmas, provided they are in a warm border.

JUNE. — *KITCHEN GARDEN.*

Care of Melons, in Frames. — The melon-plants, which are in frames, ſhould ſtill be carefully ſhaded in the middle of the day; that is, when the ſun ſhines vehemently. This ſhould now be particularly practiſed, where there is but ſlender depth of earth upon the beds, or where the plants are ſituated very near the glaſſes; for if they were in that caſe expoſed to the full noon ſun, it would be apt to ſcorch the leaves, and would alſo exhauſt the juices of the vine or runners, and that of the roots; whereby the young fruit, and even thoſe that are ſwelled to ſome tolerable ſize, would, for want of the proper nouriſhment, be greatly checked, and would thereby take an irregular growth, and become ſtunted and very ill-ſhaped. Therefore, let ſome thin mats, &c. be ſpread over the glaſſes every day, when the ſun ſhines fiercely; but this need not be done before eleven o'clock, or thereabouts; and the mats may be taken off again about two. In beds where there are twelve or fifteen inches thick of good loamy earth, the melon plants will require but moderate ſupplies of water, once in a week or fortnight, as you ſhall ſee occaſion; continue to cover the glaſſes every night with mats, till about the middle of the month.

Care of Bell-glaſs Melons. — The melon-plants which are growing under bell or hand-glaſſes, ſhould now have full liberty to run out. Let each glaſs be raiſed and ſupported upon three props, about two or three inches high, and lay the vines out carefully, and in a regular manner. Continue to cover them every night with mats, till about the middle, or towards the latter end of this month; and then, if warm ſettled weather, the covering may be entirely laid aſide, except the weather ſhould prove very wet: in which caſe, it would be proper to defend theſe plants, by a covering of thick mats, or canvas, ſupported upon hoop arches fixed acroſs the bed.

Method of Conſtructing Oiled Paper Frames for Melons, and Cucumbers. — Where it is intended to cover any of the hand-glaſs melon ridges with oiled paper frames, it ſhould be done in the firſt or ſecond week of this month. This kind of frame will be a great protection to the plants and young fruit, if cold and wet weather ſhould happen about the time of its ſetting; and it will alſo ſcreen the plants from the too great heat of the ſun. Theſe frames ſhould always be placed upon the ridges, as ſoon as theſe plants begin to advance from under the hand or bell-glaſſes; the glaſſes muſt be taken away when the frame is placed on the bed. Such perſons as are not provided with bell or hand-glaſſes, may, with the aſſiſtance of theſe frames only, raiſe good melons, provided the plants be firſt raiſed by ſowing the ſeed in a hot-bed, under a frame and glaſſes, in March, or April, as there directed, and afterwards planted out on new hot-ridges the beginning of May, and papered frames immediately placed over the ridges as ſoon as the plants are planted therein, and be covered with mats every night till the middle or latter end of this month. Theſe frames are made of thin ſlipes of wood, and are conſtructed in the manner and form of the ridge or roof of an houſe, or archways; they ſhould be made firm but light. Each frame ſhould be ten or twelve feet long, or thereabouts, and four feet and a half or five feet wide at bottom; narrowing gradually on both ſides to a ſharp ridge at top, or formed in a rounding arched manner; making the whole two feet and a half or a yard high; in forming it, a bottom frame ſhould be conſtructed with two inch and a half wide ſlips of deal, framing it the above length and width; and then have either ſtraight inch-wide rafters, or hoop arches carried from both ſides a foot aſunder, and upon theſe the paper is to be paſted, firſt drawing pack-thread both ways, for the better ſupport of the paper.

On one ſide of the frame there ſhould be two pannels, made to open on hinges; and each of theſe pannels muſt be eighteen inches wide, making them within two feet of each end of the frame. Theſe pannels are to be opened occaſionally, to examine the plants and fruit, and to do the neceſſary work about them; which is better than to take the frames off upon every occaſion. The frame being made according to the above dimenſions, get ſome paper and paſte upon it. The beſt ſort for this purpoſe is the large demy printing paper, or thick writing paper, ſuch as is ſold for eleven pence or twelve-pence a quire; and two quires of ſuch paper will cover at leaſt one of the above frames.

But, before the paper is paſted on, there ſhould be ſome ſmall twine, or packthread, drawn at equal diſtances, along the frame, and acroſs the ſlips of wood, drawing it firmly round them, and then draw ſome more contrary ways acroſs that; this will ſupport the paper, when the wind at any time happens to blow ſtrong againſt it. Then let the paper be neatly paſted upon the frame; and when it is perfectly dry, get ſome lintſeed oil, and a ſoft pliable bruſh ſuch as painters uſe; dip the bruſh in the oil, and bruſh the paper all over lightly with it. The oil will render the paper more tranſparent, and make it proof againſt rain: Theſe frames ſhould always be made, that is, papered, ſome time before they are uſed; for the oil ſhould be perfectly well dried in the paper before the frames are placed out upon the ridges.

Fill up the Alleys between the Melon and Cucumber Ridges. — The alleys, or ſpaces, between the hand glaſs melon ridges, ſhould be now filled up with warm dung and earth, if not done laſt month, in order that the roots of the plants may have full ſcope of ground to run in. Where theſe ridges are made all, or a great part above ground, the ſpaces or alleys between them not being above three or four feet wide, it is adviſeable to fill them up equal with the beds, dung below, and earth at top, the beginning of this month; and it would be of great advantage, if a quantity of new and old dung together was uſed, juſt to produce a moderate warmth; for this would throw a freſh heat into the beds, which would very much promote the ſetting and ſwelling of the young fruit. Let the dung be as high as the dung of the ridges; then lay the earth over that, raiſing the whole level with the ſurface of the ridges or beds.

Pickling Cucumbers. — The cucumber plants which were ſown the latter end of laſt month, in the natural ground, to produce picklers, &c. ſhould now be thinned. This ſhould always be done when the rough leaf begins to advance in the heart of the plants. In doing this work, obſerve to leave in each hole, at leaſt four of the ſtrongeſt plants, but never more than five or ſix, which will be ſufficient: let the reſt be drawn out with care, and clear away all the weeds. Then earth up the ſhanks of the remaining plants within a little of the ſeed leaves, preſſing them gently aſunder at regular diſtances from one another, and immediately give each hole a light watering to ſettle the earth; the plants after this will get ſtrength, and grow away ſurprizingly. Let them be often refreſhed with water in dry weather; for they will in a dry time need a little every other day.

Tranſplant the early Celery, which was ſown in February, into the Trenches. — Tranſplant celery into trenches to remain to blanch. That which was ſown early will be grown to a proper ſize for this purpoſe by the firſt or ſecond week of this month, when it ſhould be planted; and ſome of the ſecond ſowing ſhould be planted out towards the latter end of the month for a general crop. Chooſe for theſe plants a piece of rich ground in an open ſituation; then mark out the trenches by line, about a foot wide; and allow the ſpace of three feet between trench and trench, which will be ſufficient for the early plantation. Dig each trench neatly, about ſix or eight inches, or a moderate ſpade deep, laying the earth that comes out equally on each ſide, then dig the bottom level; or firſt, if thought neceſſary, if poor ground, lay the thickneſs of three inches of very rotten dung along in the bottom of each trench, and let the bottom be neatly dug, burying the dung equally, a moderate depth, then put in the plants. Plant them in one ſingle row, juſt along the middle of each trench, allowing the diſtance of five inches, or thereabout, between plant and plant in the row; as ſoon as they are planted give them ſome water, and repeat it occaſionally till they have taken root. Theſe plants will, in about a month or ſix weeks after they are planted out, require to be moderately earthed up; and this is done in order to render the ſtalks white and tender: the earthing then muſt be performed in dry days: the earth muſt be broken ſmall, and take care to lay it gently to both ſides of the plants, and not to earth them too high at firſt, leſt you bury the hearts; this earthing ſhould, after you begin, be repeated every week or fortnight, or thereabouts, till the plants are ready for uſe.

Tranſplant the Endive ſown in May for an early Crop. — Tranſplant endive for blanching; ſome of the firſt ſown plants of May will be ready for this by the middle, or towards the latter end of the month. Then put in the plants by line, about a foot aſunder every way, and let them have ſome water as ſoon as they are planted. But there ſhould not be many of theſe early ſown plants planted out; that is, not to deceive yourſelf in planting out enough for a main crop: for the plants, if they were ſown in May, will moſt of them be apt to run to ſeed before they arrive to any tolerable ſtate of maturity. Sow endive-ſeed for a principal crop, and to ſucceed thoſe which were ſown the former month. See *Auguſt.*

Sow Celery for Winter and Spring Supply.—Sow celery ſeed for a principal latter crop; this ſhould be done in the firſt or ſecond week of the month. Dig a bed of light rich earth, and lay the ſurface perfectly level; then ſow the ſeeds pretty thick, and rake them in lightly with a very even hand. In hot ſunny weather, ſhade the bed from the ſun every day, from ten till three o'clock, till the plants appear; otherwiſe, this ſeed being very ſmall, the full ſun would, in a manner, quite burn it up. Likewiſe, let the bed, in dry weather, be refreſhed every other evening with a light moderate watering. The plants from this ſowing will be fit to plant out into trenches, in July, Auguſt, and September, and to take up for the table from October till Chriſtmas, and for a ſpring ſupply.

Prick out Cauliflowers ſown in May. — The cauliflower plants which were ſown in May, for the Michaelmas crop, ſhould about the third week in this month, be pricked out in a nurſery bed of rich earth. Prepare for them a bed about forty inches broad, in an open ſituation; then put in the plants, three inches aſunder, or thereabout, and give them a little water to ſettle the earth well about their roots. It will be proper to ſhade them from the hot ſun till they have taken good root. The plants are to remain in this bed a month or five weeks, to get ſtrength, and then to be planted out for good in the places where they are to remain to produce their heads.

Care of Early Cauliflowers now arriving to Perfection.—Continue to look over the plantations of early cauliflowers now and then, in order to break down ſome of the large leaves over the young heads, according as they appear. Theſe plants, which are ſtill advancing in growth, or part coming into flower, ſhould, in very dry weather, be well watered, which will keep the plants in a growing ſtate, and produce very large flowers or heads.

Save Cauliflower Seed.—Mark ſome of the earlieſt plants when in full perfection, with the largeſt white, and cloſeſt heads, which muſt not be gathered, and the plants left in the ſame place; they will ſhoot up into ſeed-ſtalks in July and Auguſt, and ripen ſeed in September.

Aſparagus.— Aſparagus ſtill continuing in perfection; obſerve to cut or gather the buds, as directed laſt month. But let it be remembered, it is adviſeable to terminate the general cutting for the year ſoon after the twentieth or twenty-fourth of the month, otherwiſe it will weaken the roots; for as long as you continue to cut the buds, the roots continue ſending up new ſhoots, though every time ſmaller; and, if continued late in the ſeaſon, would greatly exhauſt themſelves; as the future produce next year, &c. would be diminiſhed in proportion. Before the aſparagus run up to ſtalks, you ſhould now clear the beds perfectly from weeds; for that work cannot be ſo readily done after the ſtalks have ſhot up to a great height.

Prick out Broccoli ſown in April. — Prick out from the ſeed-bed early in the month the young broccoli plants which were ſown in April. Let them remain in this bed about a month, or five or ſix weeks, and then plant them out for good.

JULY.—*FRUIT GARDEN.*

Summer Pruning and Nailing Wall-Trees. — In gardens where there are wall-trees that have not yet had their ſummer pruning and nailing, that very needful work ſhould now be done in the beginning of the month; otherwiſe, the fruit upon ſuch trees will not only be ſmall and ill grown, but will alſo be very ill taſted, in compariſon to the true flavour of theſe fruit. Beſides retarding the growth and debaſing the taſte of the fruit, it is alſo detrimental, in a very great degree, to wall and eſpalier trees, to neglect the ſummer ordering and nailing, entirely till this time; and in particular to apricots, peaches, and nectarines, and ſuch like trees as produce their fruit principally upon the one year old ſhoots. Beſides, it cauſes great perplexity to the pruner to break through and regulate ſuch a thicket, and confuſion of wood; requires treble the pains and labour, and cannot be executed with ſuch accuracy as when the work is commenced early in the ſummer. In vines, many ſmall ſhoots generally riſe, one at leaſt from every eye of the ſame ſummer's ſhoots which were laid in a month or two ago; and the ſame ſmall ſhoots muſt now, according as they are produced, be all as duly diſplaced. All other ſhoots, wherever placed, that have been lately produced, muſt alſo be rubbed off cloſe: and all ſuch ſhoots as ſhall riſe any time, this month, ſhould, according as they come out, be continually taken off. Where this is obſerved and duly practiſed, the bunches of grapes will be large and perfectly grown; and every bunch will alſo ripen more regular and ſooner by at leaſt three weeks, than where the vines are neglected and permitted to be over-run with uſeleſs ſhoots. See *May* and *January.*

Budding. — Budding may now be performed in apricots, peaches, and nectarines: plums, cherries and pears. That work may be done any time in this month, but the ſooner the principal budding is done the better. Let every ſort be budded upon its proper ſtock: apricots, peaches, nectarines, and plums, ſhould be budded upon plum-ſtocks; they generally make the ſtrongeſt and moſt laſting trees, when budded upon ſtocks raiſed from plum-ſtones, or ſtocks raiſed from the ſuckers of plum-trees: though all theſe ſorts will alſo grow upon ſtocks of one another, raiſed from the ſtones of the fruit; and alſo upon almond ſtocks raiſed the ſame way; but the plum-ſtock is always preferable for the general ſupply. Pears may be budded upon pear-ſtocks; and theſe muſt be raiſed by ſowing the kernels. Pears alſo ſucceed well, in particular for the wall, when budded upon quince-ſtocks to dwarf them. Cherries are to be budded principally upon cherry-ſtocks, which muſt be alſo raiſed by ſowing the ſtones. Such cherries, plums, or pears, as were budded laſt ſummer, or grafted in the ſpring and miſcarried, may now be budded with any of the ſame kinds of fruit; for theſe trees will ſucceed either by grafting or budding. Budding generally ſucceeds beſt when performed in cloudy weather, or in a morning or an evening after three or four o'clock; for the great power of the mid-day ſun is apt to dry the cuttings ſo much, that the buds would not readily part from the wood. However, where there are large quantities to be budded, it muſt be performed at all opportunities. In performing this work, it muſt be obſerved, that where the trees are to be raiſed for walls and eſpaliers, the budding muſt be performed low in the ſtock; that is, the height of five or ſix inches from the ground, and at five or ſix feet for ſtandards. Budding may alſo be performed now upon trees that bear fruit. What is meant by this, is, where there are wall or eſpalier trees, that produce fruit not of the approved kinds, ſuch trees may now be budded with the ſorts deſired; and the budding is to be performed upon ſtrong ſhoots of the ſame ſummer's growth. Several buds may be put into every ſuch tree; by which means the wall or eſpalier will be ſoon covered with the deſired kinds, and in two or three years after budding they will begin to bear.

JULY.—*KITCHEN GARDEN.*

Plant Peas and Beans for a late Crop in September and October. Peas and beans may ſtill be ſowed the three firſt days in this month, it muſt not be later but the ſooner the better. Though thoſe peas and beans which are planted at this ſeaſon, do not always ſucceed in bearing abundantly, it will, however, where there is ground at liberty, be worth the trial, to put in a few of each, at two or three different times in this month; and if the ſeaſon ſhould prove ſomewhat moiſt, there will be a great chance of reaping a tolerable crop from them in September; at which time they will be a great rariety. The beſt beans to plant now, are the ſmall kinds; none better than the white bloſſom, ſmall Spaniſh, long pods, mumford, mazagan, and the like kinds; I have gathered plentifully from theſe ſorts at Michaelmas. But the large kinds of peas, ſuch as marrowfats, &c. may ſtill be ſown; and it will be alſo proper to ſow a few of the beſt kinds of hotſpur and dwarf peas. Obſerve, that if the weather and ground be very dry, it will be proper to ſoak the peas and beans in water for a few hours. Let the water be taken from a pond or river, and let the ſeed lie therein eight or ten hours; then ſow or plant them. Let theſe late crops be ſowed and planted in the moiſteſt part of the ground, where convenient, but not in a ſhady place, for in ſuch a ſituation the plants would draw up, and come to nothing; and remember to allow them ſufficient room between the rows, for much depends upon that at this time of ſowing. Prepare ſuch pieces of ground as are vacant, in order to receive ſuch ſeeds and plants as are proper to ſupply the table with neceſſary productions in autumn and winter.

Sow Broccoli Seed, for a late Spring Supply. — Now ſow alſo ſome broccoli-ſeed to come in for a late ſpring crop. This is to be the laſt ſowing, and ſhould be done ſome time before the tenth of the month. This ſeed ſhould be ſown in a rich ſpot, where the ſun has not much power. The plants raiſed from this ſowing will be ready to plant out for good in the middle or towards the latter end of Auguſt, and beginning of September, and will produce their heads in April, and in the beginning of May.

Plant Kidney beans, for a late Crop. — Plant a late crop of kidney-beans. Either the dwarf or running kinds may ſtill be planted, or ſome of both; but moſt of the dwarfs for any main crops. But the ſeed muſt be put into the ground the firſt week in this month, particularly that deſigned for a full crop; more may be planted about the middle and latter end of the month, of the dwarf kinds, to continue the ſucceſſion of beans in gathering till Michaelmas or longer; as they will, in mild autumns, continue till the middle or end of October. But in planting theſe beans, it will now be proper to obſerve the following precaution. That is, if the weather be at this time very hot, and the ground alſo very dry, it will, in that caſe, be adviſeable, before the beans are planted, either to water the drills, or lay the beans to ſoak in river or pond water. Let them be laid in the water in a morning, and continue there about five or ſix hours, and then being immediately planted. Moſt of the running ſorts are exceeding profitable for the ſervice of a family, for they are ſurprizing great bearers; but, in particular, the ſcarlet flowering bean; and there is a variety of this, that differs from it only in colour, which both in the ſeed and flowers, is white; but is not to be diſtinguiſhed from the ſcarlet, neither in the manner of growth nor mode of bearing; and both the varieties are very proper for this plantation: the large white Dutch running kinds are alſo very proper to plant now. The advantage of planting theſe running kinds is very great; for thoſe that are now planted, will, after they begin, continue bearing till the cold weather deſtroys the plants. But it ſhould be obſerved that where there are not the convenience of ſticks or poles for theſe plants to climb up upon, they will not ſucceed; and where that is the caſe, it will be beſt to plant none but the dwarf kinds. For the early crop, ſee *April.*

Tranſplant Cauliflowers ſown in May. — The cauliflower plants which were ſown in May, for the autumn crop, muſt now be planted out where they are to remain. This plantation will begin to produce their heads in the beginning or middle of October; and will continue, ſometimes, coming in gradually, till the middle or end of November, or till near Chriſtmas, if an open mild ſeaſon.

Sow Carrots for Autumn Uſe. — In the firſt or ſecond week in this month, you may ſow ſome carrot-ſeed, to raiſe ſome young carrots for the table in autumn. The carrots raiſed from this ſowing will come into uſe after Michaelmas, and will be very fine in October and November, &c. Chooſe light ground, which dig a proper depth, and directly while freſh turned up, let the ſeed be ſowed moderately thin, and rake it in evenly. When the plants are come up an inch or two high, let them be cleared and thinned to ſix or eight inches diſtance.

Sow Turnips for Autumn and Winter's Supply. — The plants raiſed from this ſowing will be in excellent order from about Michaelmas till Chriſtmas. It will be a great advantage if there falls ſome rain, to take the opportunity of ſuch times to ſow the feed. Great care ſhould be taken not to ſow it too thick: ſow it as regularly as poſſible, and take the ſame care in raking it into the ground.

Sow the black Turnip-rooted Radiſh for Winter's Supply.—Now is the very beſt time in the whole year, to ſow the large black turnip-rooted radiſh. There are two ſorts, one black, and the other white, and are generally known by the name of the black or white Spaniſh radiſh. The black ſort is in moſt eſteem, grows as large as ordinary turnips, and very hardy to ſtand the winter; they are by many people much admired for autumn and winter, to ſlice in ſallads, or eat alone, raw; the moſt proper time to ſow the principal winter crop, is between the tenth and twenty-fourth; they ſhould be ſowed in an open ſpace of freſh digged ground, broad caſt, and trod down, and raked in regularly. When the plants have been come up ſome time, they muſt be hoed out to about ſix or eight inches diſtance; they will then have proper room to ſwell, and will be ready to draw for the table about Michaelmas, and will continue good all winter. Sow alſo ſome ſmall Italian turnip-radiſh for autumn.

Gather Seeds. — Gather ſeeds of all ſorts according as they ripen. Let this be done always in perfect dry weather; cutting or pulling up the ſtems with the ſeeds thereon, and let them be ſpread immediately in a dry place where the air can freely come. There let them lie to harden the ſeed, obſerving to turn them now and then; and when they have laid a fortnight, or three weeks, the ſeed ſhould then be beaten out, and well cleaned from the huſks and rubbiſh, and put up in boxes or bags, and continue the ſucceeding months.

Tranſplant Leeks, and Onions ſown in February. — Chooſe the ſtrongeſt plants, and trim the roots, and cut off the tops of their leaves; then plant them, obſerving to put ſix rows in each bed, and ſet the plants the diſtance of ſix inches from one another in the rows.

Gather Herbs for Drying. — Gather mint and balm, pennyroyal, ſweet marjoram, as alſo carduus, and all ſuch kinds of herbs as are now in flower, in order to dry, to ſerve the family in winter. Theſe kinds of herbs ſhould always be cut for the purpoſe of drying, when they are in the higheſt perfection, which is when the plants are nearly of full growth, and juſt coming into flower. Let them be cut, in dry weather, and ſpread, or hung up in a dry airy place, out of the reach of the ſun; and there let them dry gently; for they ſhould be always dried in the ſhade. Likewiſe gather herbs to diſtil. Many of the proper kinds will now be arrived to full growth and advancing into flower; and that is the proper time to cut all ſuch herbs as are intended for the purpoſe of diſtilling. Alſo gather ſome chamomile flowers, and the flowers of marigolds and lavender, to lay up ſome for the future ſervice of the family. Let them be gathered in a dry day, and ſpread to dry in a ſhady place; then put them up in paper bags till wanted.

AUGUST.—*FRUIT GARDEN.*

Fig Trees. — Take care of the fig trees; the figs will now be full grown, and will begin to ripen, and therefore require a due ſhare of ſun to promote their ripening, and to give them their true flavour. All the ſtrong ſhoots muſt therefore be now laid in cloſe to the wall; but take care to uſe the knife on theſe trees but very little at this time. Cut off no ſhoots but ſuch as grow directly on the front of the branches: lay in all the fair growing ſide ſhoots; for theſe young ſhoots that are now laid in, are to bear the fruit to be expected next year; and therefore, as theſe trees produce their fruit upon none but the year-old ſhoots, be careful to leave enough at this time; for what is not wanted to lay in at the general ſeaſon of pruning, can at that time be eaſily cut away. But, whatever you do, be ſure not to ſhorten any of the ſhoots, but lay in every one at full length; for the ſhoots of theſe trees muſt never be ſhortened, becauſe they are the only bearing wood for next year, and as they bear principally towards their upper ends, ſhortening would deſtroy the beſt fruitful parts thereof, and throw them into a redundancy of uſeleſs wood the following ſummer. Obſerve to lay them in regularly, not acroſs one another, and then let them be well ſecured, for the wind and rain have great power over theſe trees on account of their broad leaves.

Budded-Trees. — Go over the ſtocks or trees which were budded in July, and let all the bandages be looſened. This ſhould always be done in about three weeks, but never exceed a month, after the budding is performed; otherwiſe, as the bud will ſwell, the ſap will be ſtopped in its regular courſe, and the parts about the bud will be pinched, and will ſwell irregularly. Likewiſe examine that part of the ſtock below the bud, and when there are any ſhoots ſent forth in that place, let them be taken off cloſe.

Defend Wall Fruit from Inſects, Birds, &c. — Waſps and flies are particularly to be guarded againſt, for theſe inſects will devour the moſt delicate fruit at a ſurpriſing rate, and, if not prevented, make great havock. The only method to prevent this, is to continue to place baits in different parts of the trees to catch them; that is, let a quantity of large phials be filled with ſugared, or honey water, and hang three or four in each of the principal trees; this will greatly protect the fruit: for the ſweetneſs of the water will entice the inſects to neglect it, and they will continually hover about the mouth of the phials; numbers will daily creep in to drink, and when once they enter not one in an hundred can get out again; beſides the bottles of ſweetened water, let alſo ſome ſmall bags made of thin crape or gauze be put over ſome of the fineſt and ripeſt bunches of grapes. Theſe bags ſhould be made juſt ſo large as to contain one bunch of fruit: this will effectually keep off the inſects, and alſo the birds; the latter will devour theſe fruit at a vaſt rate, if they can come at them, eſpecially the ſparrows. But the birds you may keep from the fruit by fixing nets before the vines, or hanging up ſcare-crows of feathers, or diſcharging a gun or piſtol: but the moſt certain method to preſerve

ſerve ſome of your fineſt bunches of fruit from all devourers, is to bag them as before directed. Or, for want of crape-bags, &c. may uſe thoſe of white paper, but theſe do not ſucceed ſo well, for the ſun is then too much excluded from the fruit; and in wet weather, the paper being wetted, it adheres to the bunches and rots them; whereas the ſun and air have free acceſs through the crape, and when wet they will very ſoon become dry again; and if wet weather continue, no inconvenience attends the fruit by means of the bags.

AUGUST.—*KITCHEN GARDEN.*

Sow Spinach, for Winter and Spring Supply.—This muſt be done ſome time in the firſt or ſecond week in the month. But in poor ground, and cold ſituations the ſeed ſhould be ſown in the firſt week; but in rich warm ground it ſhould not be ſown till the ſecond week in the month, for if ſowed much ſooner in rich ground, the plants are apt to grow too rank before winter, and apt to fly up to ſeed early in the ſpring. Chooſe a piece of ground that lies tolerably dry in winter, and immediately ſow the ſeed, and tread it down evenly, and then rake it into the ground. Obſerve, it is the prickly ſeeded kind that is to be ſown now, for this ſort will beſt endure the cold and wet in winter. When the plants are come up, and got leaves an inch broad, or thereabouts, they muſt then be thinned, and cleared from weeds; thin the plants regularly, leaving them the diſtance of three or four inches, or thereabouts, from one another; they will then have proper room to ſpread, and gather ſtrength, to be able to endure the cold. Beſides, when ſpinach is allowed to ſpread itſelf regularly, the plants will produce very large and thick leaves; and every ſuch leaf is worth three that is produced from ſuch plants as crowd one another. Obſerve, you ſhould weed the plants every month both Summer and Winter.

Sow Cabbage Seed for next Spring, and Summer Supply.—Sow early cabbage ſeed, to produce plants for the ſervice of next ſummer. Alſo ſow the large autumn kinds to ſucceed the early crops, and for autumn ſupply, &c. The proper early ſorts to ſow now, are the early dwarf, early and large ſugar loaf, the early Batterſea, and Yorkſhire kinds, &c. But this early ſeed muſt not be ſown until ſome time between the ſixth and the twelfth of the month; nor muſt it be ſown later; there being an advantage in ſowing it juſt at that time; for was the ſeed to be ſown ſooner, many of the plants would be apt to run to ſeed in March; and was it to be ſown later in the month, the plants would not get proper ſtrength before winter.

Sow Onions for a Winter and Spring Supply.—This being the moſt eligible ſeaſon to ſow the general crop of winter and ſpring ſervice, and for early heading ſummer onion; it muſt be done in the firſt, but at fartheſt the ſecond week in the month; ſow the ſeed tolerably thick, but as equal as can be; then tread it in, and rake the ground evenly, that the ſeed may be equally covered, and the plants riſe regularly in every part of the beds. The plants from this ſowing will ſupply the table in the early part of winter and all the ſpring, for ſallads or other uſes, and continue till April and May; and if you let ſome of them ſtand till June, they will bulb and grow to a tolerable ſize, but will ſoon after run to ſeed. Sow alſo ſome Welſh onions; this is done in caſe the others ſhould be deſtroyed by the froſt; for the Welſh onions will ſurvive almoſt the ſevereſt winter; notwithſtanding their blades will ſometimes die down to the ground in November or December, the roots remain ſound, and new leaves will ſprout up again in about ſix weeks or two months after the others are decayed. But it is adviſeable alſo, to ſow a portion of each ſort about the middle, or towards the latter end of the month, for late ſupply in the ſpring, as they will not run ſo ſoon as the others.

Sow Radiſh Seed for Autumn Supply.—Radiſh ſeed may ſtill be ſown twice this month to raiſe ſome plants for autumn ſervice. If you ſow this ſeed in the beginning of the month, the plants will be ready about the beginning or middle of September; and that ſown about the middle, or towards the latter end, will be fit to draw towards Michaelmas, and will continue tolerably good all October. The proper ſorts of radiſh ſeed to ſow, at this time, for autumn crops, are the ſalmon, or ſcarlet kinds; and the ſhort-top radiſh. Sow alſo ſome of the ſmall white Italian turnip-rooted radiſh to come in next month, when they will make a pretty variety at table, and eat very agreeable in ſallads or alone. Alſo ſow a crop of black Spaniſh turnip-radiſh for autumn and winter.

Sow Cauliflower Seed for the early or General Crops.—Cauliflower ſeed ſhould be ſown towards the latter end of this month, to raiſe ſome plants, to produce the early and general crop next ſummer. The proper time to ſow the ſeed is ſome time between the eighteenth and twenty-fourth of the month; and it muſt not be ſown ſooner than that time, otherwiſe the plants will be apt to button (as it is called) or flower, in winter, or early in the ſpring, in their infant ſtate: which flowers never exceed the ſize of an ordinary button, and thereby you are diſappointed of having an early crop, at the due ſeaſon; or if ſowed late, the plants will not acquire a proper growth to reſiſt the winter's froſt; therefore mark the above time; but the London gardeners, who raiſe prodigious quantities for public ſupply, generally ſow their main crop on a particular day, (the 21ſt of this month,) having from long experience proved that to be the moſt eligible period of ſowing this crop of cauliflowers, for next ſummer's general ſupply. But in order to have a more certain crop and regular ſupply of cauliflowers, it will be proper to ſow ſome ſeed at two different times this month. The firſt and main ſowing muſt be at the time before mentioned; and the general rule is to allow the diſtance of a week, between the firſt and ſecond ſowing.

The firſt ſown plants are principally for the earlieſt and firſt general crop, and a quantity of which ſhould be planted out for good, in the latter end of October, under bell or hand glaſſes, or a parcel may be planted under a ſouth wall, and there remain, without any other ſhelter during the winter. They will ſometimes ſtand it tolerably well; but, if you chooſe it, you may alſo at that time plant a parcel of the firſt ſown plants in a bed or border, and arch it over with hoops, in order to be occaſionally ſheltered with mats till tranſplanting ſome time next ſpring in March. Sow the ſeed, and rake it in with particular care; and with the rake, teeth downward, in its proper poſition, draw the earth evenly over the ſeed: or in another method of ſowing, the bed when digged, being juſt raked ſmooth, ſow the ſeed, and ſift over it about a quarter of an inch of light earth. In dry weather let the bed be from time to time moderately watered. When the plants are come up, continue, in dry weather, to water the bed moderately, at leaſt every two days. Then, about the twentieth, or ſome time between that and the twenty-fifth of next month, the plants ſhould be pricked out from the ſeed bed. See *September* and *October*.

Management of Artichoke Plants.—Examine now the artichoke plants, both of the old plantations, and thoſe planted laſt March, or April. Many of theſe plants will now be in fruit; and, beſides the principal or top fruit, there will raiſe many ſmall heads or ſuckers from the ſides of the ſtems; but in order to encourage the principal head to grow to a large ſize, moſt of theſe ſmall ſide ſhoots ſhould be diſplaced. This practice is neceſſary, if you prefer one large handſome head to three or four ſmall ones; but when you practice this, the ſuckers or ſide heads ſhould always be taken off, before they exceed the ſize of an egg; and theſe are in ſome families dreſſed and eaten. Theſe, the gardeners about London, call ſuckers: they gather them as above, and tie them in bunches, and carry them to market, where they have a ready call for them, in that of Covent-garden and Spitalfields, &c.

Sow Lettuce Seed for Autumn, Winter, and Spring Supply.—Sow lettuce ſeed this month for uſe this autumn, and the following winter and ſpring; the firſt ſowing ſhould be in the firſt week; the other at the end of the month. The principal ſorts for ſowing now are the green and white cos lettuce, Cilicia, brown-dutch, common, white, and hardy green cabbage lettuce; but you may alſo ſow ſome of any of the other kinds. The firſt ſowing is to be performed ſome time before the tenth of the month, and is to raiſe plants for ſupplying the table in October, November, and December, the ſecond ſowing muſt be done ſome time between the eighteenth and twenty-fourth of the month; and the plants raiſed from this ſowing are ſome to be planted out in September, for winter ſupply: and others, ſuch as Cilicia, brown-dutch, common, white, and hardy green cabbage lettuce, to remain where ſowed, and thinned as wanted in winter and ſpring; and a good quantity of the cos, and other lettuces be planted out in September and October, upon warm borders in order to ſtand the winter, to ſupply the table next March, April and May. See *September* and *October*.

Sow Endive, for a late Spring Crop.—Sow ſome green curled endive the beginning of this month, to plant out the middle and end of September, and in October for a late ſpring crop. The beſt endive to ſow now is the green curled ſort; this ſort is not only the beſt for uſe, but the hardieſt, for it will endure wet and cold in winter better than any other kind. But you may likewiſe ſow, as a variety for a ſallad, ſome of the white curled ſort. See *May* and *June*.

SEPTEMBER.—*FRUIT GARDEN.*

Tranſplant Strawberries.—Now is a proper time to plant ſtrawberries; and if moiſt weather, it may be done any time in the month: but if the weather be very dry and hot, it will be proper not to begin that work till the middle, or towards the latter end of the month. The ſtrong young runner plants of the ſame year, taken from beds that bear well, are the proper ſets for planting; ſuch as adviſed next month and in June: and if any were then (June) planted out in nurſery-beds, as there directed, they will be now in fine order for this plantation. Theſe plants ſhould be allowed good ground; let it be well dunged and neatly digged, and lay it out in beds four feet broad, allowing alleys between the beds from eighteen or twenty inches, to two feet wide, for the convenience of going in to weed, water, and gather the fruit. The plants are to be ſet in rows lengthway the beds; the rows fifteen or eighteen inches aſunder, and the plants to be ſet the ſame diſtance from one another in the rows.

Or they may be planted in borders along the front and back of eſpalier-trees or under walls, hedges, &c. or ſome may be planted by way of an edging to borders, or where convenient: the wood ſtrawberries will ſucceed both in the ſhade under buſhes, trees, &c. and in a free expoſure, but the other ſorts ſhould generally be allowed an open ſunny expoſition. It will be moſt proper to do that work in moiſt weather, if poſſible. The proper ſorts of ſtrawberries to plant are: The ſcarlet ſtrawberry. The hautboy.

The large Chili ſtrawberry. The white and red wood-ſtrawberries. The pine-apple ſtrawberry, having a greeniſh fruit. The Alpine, everlaſting, or prolific ſtrawberry.

This laſt ſort is remarkable for its fruitfulneſs; for the plants continue to produce fruit from June to November, and if ſheltered with a common frame and glaſſes, will, if open weather, continue bearing till Chriſtmas. But the fruit of this ſort is in the greateſt perfection in July, Auguſt, and beginning of September.

Guther early Apples and Pears.—Now begin to gather apples and pears for keeping, according as they are fit; many of the autumn ſorts will be ready to take down towards the middle or latter end of this month. This work muſt always be done in a perfectly dry day; and be ſure to let the fruit be alſo quite dry before you begin to pull them; and all the fruit which are for keeping ſhould hang their full time on the the trees, but eſpecially the late autumnal and winter pears and apples. See *October*.

About the latter end of this month, many of the winter fruits will be fit to gather; but if the weather is fine, let them hang on the trees till the beginning of October. When the apples or pears have hung their full time on the trees, they will eaſily quit the wood on being handled; and when they begin to drop off apace, that is a certain ſign of their maturity, and that they may be gathered. See *October*.

SEPTEMBER.—*KITCHEN GARDEN.*

A Complete Practical Method of rearing Muſhrooms.—This is now the ſeaſon to begin to prepare the dung for making muſhroom-beds. Theſe beds ſhould be made of the beſt warm horſe ſtable dung, and about the beginning, or any time this month, it will be proper to provide a neceſſary quantity, ready for that purpoſe; before you work the dung up in a bed, it ſhould be toſſed up together in a heap till the firſt great heat is over; this is generally effected in a fortnight or three weeks time, or thereabouts, it will then be in right order, and you may proceed to make the bed. But before you make the bed it is proper to provide a ſufficient quantity of good muſhroom ſpawn: this is a material article; and a proper quantity muſt be procured to plant into the bed to produce the muſhrooms, for this ſpawn contains the plants in embryo. This is frequently found in the dung of old cucumber or melon, or other decayed dung of hot beds; it is alſo often to be met with in dung hills, which have lain ſix or eight months or more; ſpawn is alſo to be found in paſture fields, and ſhould be ſearched for in thoſe places where you ſee muſhrooms riſe naturally; but I generally prefer the ſpawn found in dung, either in old hot beds or in old dung hills. I have often found excellent ſpawn in the farmer's dung hills; ſuch as we commonly ſee piled up in large heaps in the lanes, or on commons near their fields; and you will generally find it moſt of all in thoſe dung heaps which conſiſt chiefly of horſe ſtable dung, obſerving to ſearch in ſuch as appear to have laid for ſeveral months. Spawn is commonly found in ſearching as above, in lumps of dry rotten dung; it is a white fibrous ſubſtance, running and ſpreading itſelf in the ſaid lumps of dry rotten dung, appearing of a white ſtringy or filamentoſe nature, and if of the true ſort, has exactly the ſmell of a muſhroom. Let theſe lumps be taken up carefully, dung and ſpawn together, obſerving to preſerve the pieces as entire as poſſible, laying them at the ſame time in a wheel-barrow or baſket with the ſame care; when you have gathered enough for your purpoſe, let the lumps be laid in a dry place, and covered with ſome dry litter till the bed is ready. But if the pieces of ſpawn are wet, or very damp, you may lay them thinly on a mat in a dry ſhady place, where they may dry leiſurely; then cover them as above. I have been obliged often to buy my ſpawn of the market gardeners in the neighbourhood of London; but particularly thoſe called the Neat-houſe gardeners near Chelſea, alſo about Lambeth and places adjacent; where many of the gardeners labourers go about at this ſeaſon and collect great quantities for ſale. It may, if cloſely packed up in hampers, be ſafely conveyed to a great diſtance. I have more than once ſent it above an hundred and fifty miles. It is ſold from about five to eight or ten ſhillings per buſhel.

When you have obtained the ſpawn, you may then begin to make the bed as ſoon as the dung is in a right condition for that purpoſe. Chooſe a dry ſpot either in the melon-ground, to make the bed on, or on any other dry ſheltered ſituation; and the bed may be made either wholly upon the ſurface of the ground, or in a ſhallow trench only ſix inches deep, the width and length of the bed, and the excavated earth of the trench will ſerve to earth it. Mark out on the ground the width and length of the bed, according to the quantity you intend to raiſe; it is to be made ridgeways, like the roof of an houſe, about four feet high. Bring in the dung, and lay the bottom of the bed to the full extent: and, as you advance in height, draw both ſides in gradually from the bottom, till you bring it, as it were, to a ſharp edge at the top. As you proceed in making the bed, obſerve to ſhake and mix the dung well together, but do not tread it, but beat it down firmly with the fork, and permit the whole to ſettle gradually of itſelf. Thus let the bed be carried on till you have raiſed it to the height of, at leaſt, three feet and a half, or four feet high, finiſhing the whole in the form of a ridge of a houſe, as directed. Having made the bed, you muſt let it remain for at leaſt a fortnight, or three weeks, or a month, according to its ſubſtance and extent, before you put in the ſpawn, or till the heat is become quite moderate; for if the ſpawn was to be put in while the heat is ſtrong, it would be entirely deſtroyed; therefore have two or three long ſticks thruſt down into the dung, to pull up occaſionally to try the heat; which ſhould be quite mild, and reduced to a very low warmth, before you venter the ſpawn in: for this is very delicate; impatient both of too much heat and copious moiſture.

Remember, after the bed is made, if there ſhould happen to fall much rain before it is ready for the ſpawn, to cover the whole a good thickneſs at the top with long dry litter, for much wet would ſpoil the bed. When the bed is in a due condition, let the ſpawn be brought out in a dry day, and plant it in rows lengthways of the bed, obſerviug to begin the firſt row within about ſix inches of the bottom. Plant the pieces of ſpawn in the dung, obſerving to put them juſt within the ſurface of the bed, and let them be put in about five or ſix inches aſunder; when you have finiſhed one row, begin another ſix or eight inches from the firſt, and ſo proceed till you have planted the whole. When this is done, let the ſurface of the bed be made quite ſmooth, by beating the dung gently with the back of your ſpade. Then let every part of the bed be covered with ſome rich dry earth about an inch and a half thick; let this alſo be made quite ſmooth by uſing the ſpade as above. Then let the whole be covered with ſome clean and dry ſtraw, or dry long ſtable litter, a foot thick at leaſt, to keep out the wet and cold; obſerving, however, if you have any doubt, of the bed recovering a vigorous heat again ſoon after being ſpawned and cloſely carthed over, which confines the heat and hot ſteam; you may cover it only but a quarter or half the thickneſs at firſt, or not at all for a few days or a week, or fortnight, if a very ſubſtantial bed, and the weather is dry; but if rain falls, defend it above with the ſtraw, or dry long horſe-ſtable litter; for if the bed is ſuffered either to have too much heat or wet, all is loſt, ſo delicate is the ſpawn; and requires therefore the greateſt precautions in the firſt ſetting.

When heavy rains fall, examine the above covering; and if you at any time find that the wet has penetrated through to the bed, let the wet ſtraw be removed, and lay ſome freſh on next the ſurface. In time of ſevere froſt, or ſnowy weather, the depth of covering ſhould be augmented with more dry ſtraw, and over this ſome mats or canvas cloth. Or, after the bed has been ſpawned and covered ſome conſiderable time, and the muſhrooms do not ſeem to come freely, or that the warmth of the bed appears ſpent, you may remove the covering, and apply the next bed a quantity of warm, dry, horſe-ſtable litter, near a foot thick, and other dry litter over that, and this will promote a freſh moderate heat in the bed, and prove very beneficial.

But theſe beds, in the ſummer ſeaſon, may ſometimes have the covering of litter taken off during the time of a moderate warm ſhower, and in very hot weather may now and then have little ſprinklings of water. Theſe beds, if properly made, and taken care of as above, will begin to produce plenty of good muſhrooms in five or ſix weeks, or thereabouts; and will continue ſometimes bearing for ſeveral months. The ſpawn, when it begins to run, ſpreads itſelf very faſt every way, and the plants will riſe over the bed. But ſometimes a muſhroom bed will not begin to yield any plants till two, three or four months after it is made; but when that happens, you ſhould not deſpair, for ſuch a bed, after it begins, often produces abundance of fine muſhrooms, and continues to do ſo a long time. You muſt remember, when a muſhroom bed has done producing, and you pull it to pieces, to ſave all the freſh ſpawn to plant in new beds; for the ſpawn will keep good for ſeveral months, provided you keep it in a dry warm place, and cover it with dry litter. I have ſometimes planted muſhroom ſpawns on the late made cucumber ridges; that is, thoſe made in April and May, and in a month or two after, introduced the pieces along the top edges of the bed into the earth, where it has ſucceeded and produced a great number of muſhrooms in September and October; obſerve, when you expect them to appear, to cover the places with litter.

Plant out Lettuces, ſown early in Auguſt for Autumn and Winter Supply.—The crop for this autumn and beginning of winter ſervice, ſhould be planted out the beginning and middle of this month, in any bed, or border, in rows ten or twelve inches aſunder; but thoſe of the late Auguſt ſowings, intended to ſtand the winter for ſpring ſupply, are to be planted out in October.

Plant out Cauliflowers, into Nurſery-beds, which were ſown in Auguſt.—The cauliflower plants which were ſown in Auguſt will require to be planted out into a nurſery-bed about the middle or twentieth of this month. Mind to draw out ſome of the beſt plants from the ſeed-bed, rejecting ſuch whoſe ſtems are crooked and black. Plant them in rows about three or four inches aſunder, and allow near the ſame diſtance between plant and plant in the row; obſerving not to plant them ſo deep as to bury their hearts, for that would deſtroy them. If there ſhould happen to fall heavy rains, it will at ſuch time be proper to put on the lights, to defend the plants therefrom; for too much moiſture would prove very prejudicial to theſe young plants, and would occaſion their ſhanks to turn black and rot.

Neceſſary Care of Michaelmas Cauliflowers, ſown in May.—Some of the cauliflowers which were planted out in July, for the Michaelmas

mas crop, will begin to ſhew their heads about the end of this month, or beginning of next. If the weather in this month proves dry, form the earth like a baſon round each plant, and pour water therein; this will encourage them to grow freely, and produce large heads in October and November; for if they are ſtinted now for want of moiſture, their heads will be ſmall at their proper ſeaſon.

Prick out Cabbage Plants, ſown laſt Auguſt for an Early Crop next Summer.—The cabbage plants which were ſown the firſt or ſecond week in Auguſt for an early crop next ſummer, ſhould be pricked into nurſery-beds. Some of the forwardeſt about the beginning, and the reſt in the middle or latter end of this month. Let the principal ſupply of the early cabbage plants remain in the nurſery-beds in a warm ſituation, till February, or March, before you plant them out for good; for it ſometimes happens in ſevere winters, that many of the plants which are planted out early into a more open expoſure, are killed by the froſt. See *Auguſt* and *February.*

Tranſplant Celery into the Trenches which was ſown in June for the Winter and Spring Supply. — Plant out more celery the beginning of this month for a ſucceſſional winter crop, and about the middle or latter end of the month plant out for a late winter crop, and for ſpring ſupply. Trim the roots and tops of the celery, and plant one row in each trench. Let the plants be ſet about four or five inches aſunder in the row, and water them directly. Obſerve never to omit earthing them up every month till it is gathered. See *December.*

Plant out Endive ſown laſt Auguſt for a Winter Crop. — Plant out endive the beginning of this month, for a general winter crop; let theſe be planted in a dry ſpot in a warm ſituation, allowing them a foot diſtance each way. About the middle, or towards the latter end of this month, you ſhould plant out ſome endive on a warm border under a ſouth wall, to remain till December and after Chriſtmas before you begin to blanch it. This, if it ſurvives the froſt, will be acceptable for ſallads, and other uſes, in January, February, and March. See *April* and *May.*

Chervil and Corn Sallad. — Sow chervil and corn ſallad the beginning of this month, if not done in Auguſt, for winter and early ſpring uſe; the former for ſoups, and both of them alſo for ſallads. See *Auguſt.*

Gather ripe Seeds. — Gather ſeeds in dry weather, of ſuch plants as now ripen, ſuch as lettuce, leeks, onions, cauliflowers, &c. which you muſt well attend to in theſe kinds particularly, according as they acquire maturity, and before attacked by the autumnal rains or mildew.

OCTOBER. — *FRUIT GARDEN.*

Gather Winter Pears and Apples. — Winter pears and apples ſhould in general be gathered this month. Some will be fit to take down the beginning of the month, others will not be ready before the middle, or towards the latter end. To know when the fruits have had their full growth, you ſhould try ſeveral of them in different parts of the tree, by turning them gently upward; if they quit the tree eaſily it is time to gather them. But none of the more delicate eating pears ſhould be permitted to hang longer on the trees than the middle of this month, eſpecially if the nights are inclinable to froſt: for if they are once touched with the froſt, it will occaſion many of them to rot before they are fit for the table, even if ever ſo good care is afterwards taken of them. Obſerve, that for all the principal keeping fruits, a dry day muſt be choſen for this work, and alſo let the trees and fruit be quite dry before you begin to gather; about eleven or twelve o'clock is the beſt time in the day to begin, and may be continued till three or four in the afternoon; obſerving likewiſe, that the capital fruits deſigned for long keeping ſhould all be carefully pulled one by one, and put into a baſket, taking care to lay them gently, that they may not bruiſe one another. According as the fruit are gathered, let them be carried into the fruitery, or any other dry place, and lay them in heaps, each ſort by themſelves. Thus let them lie together about a fortnight to ſweat; this will make them keep better, and alſo render their flavour much finer, than if they were laid up for good as ſoon as they are gathered. When they have lain that time, let all the choice keeping fruit be then carefully wiped one by one with cloths, and lay them up where they are to remain. Some of the fineſt eating pears and apples, you may pack up in baſkets or boxes; obſerving to put ſome clean wheat ſtraw at bottom, and alſo round the ſides of the baſkets or boxes, and, when they are filled, lay ſome ſtraw at top, and then cover the whole with dry ſtraw, a conſiderable thickneſs, to exclude the damps and free air: for this is of conſiderable advantage in promoting their ſound keeping. The more inferior or common kinds, for general ſupply, may be laid on the ſhelves and floor of the fruitery; firſt laying ſome clean ſtraw, then lay the fruit upon this, obſerving, if there is plenty of room, to let them be laid only two or three layers thick, otherwiſe you may lay them in ſeveral layers one upon another; covering the whole with dry clean ſtraw, a foot thick at leaſt, to exclude the damp air, froſt, &c. whereby the fruit will keep much better than if they remained open, or but thinly covered; as the damps and air, when fully admitted, haſten the decay of the fruit.

OCTOBER. — *KITCHEN GARDEN.*

Plant Beans for early Summer Supply. — The latter end of this month, you may plant ſome beans, for an early crop the ſucceeding ſummer. Thoſe which are planted now, if they ſurvive the the winter's froſt, &c. will come in for uſe the end of May or beginning of June. The Mazagan bean is the beſt to plant at this ſeaſon, for they will come earlier than any other, and are excellent bearers, though but of humble growth; and they will ſtand the winter better than the larger ſorts. A warm border under a ſouth wall, or other ſouth fence, is the beſt ſituation to plant theſe beans in at this ſeaſon. In planting early beans, it often proves very ſucceſsful, firſt to ſow the beans pretty thick in a bed of rich earth; and when they come up an inch or two in height, tranſplant them into the border. The method is, this: dig a bed about three or four feet broad of good earth in a warm corner; this done, ſcatter in the beans about an inch aſunder, and immediately cover them with the earth. In the ſpring take them carefully up out of the ſeed-bed, with their full ſpread of roots, and as much earth as will hang about them; pull away the old beans at the bottom, and trim the end of the perpendicular root; aud then plant them in rows three or four feet aſunder, obſerving to cloſe the earth well about every plant; they will ſoon take root and grow freely.

One reaſon for this practice is, that beans which are tranſplanted will come in ſooner by a week or ten days, than thoſe which are not; though the ſeed of both are put into the ground the ſame day. Another thing is, that when the beans are thus firſt ſown in a ſmall bed, and ſevere froſts afterwards ſet in any time before the plants are ready to be tranſplanted; in that caſe the ſeed, or plants, by being all together within a ſmall compaſs, can be readily protected by placing a frame, or ſome other covering over them; and by that means be preſerved; when thoſe in the open ground are ſometimes killed, or greatly damaged by the froſt.

Sow Peas for an early Summer Supply. — They may be ſowed in the middle or latter end of the month, and the produce will come in at May and June, provided they eſcape the froſt; but, however, if they are ſown any time in the month, it will not make a great difference; and indeed thoſe ſown in the latter end of the month will have the better chance to ſucceed. The earlieſt hotſpur are the proper ſort of peas to ſow at this time. Chooſe ſuch ſeed as are new, plump, and ſound. There are ſeveral ſorts of the hotſpurs; ſuch as the Golden, the Charlton, the Reading, the Maſter, and Nichols's; but the Charlton, Golden, and a variety thereof, called Nichols's early pea, are thoſe which we now generally recommend to ſow for the beſt early crop. A warm ſouth border, under a wall or other fence, is the proper place to ſow them in. Scatter the peas therein pretty thick, but as regular as can be, and cover them immediately about an inch and a half deep with earth.

Tranſplant Lettuces ſown the beginning and end of Auguſt. — Lettuces for the winter ſervice of the early Auguſt ſowing; in the beginning or middle of the month ſhould be planted out in beds of rich light earth, in a ſheltered ſituation, ſix or eight inches aſunder: they will ſupply the table before and after Chriſtmas. The cos and other lettuces which were ſown at the end of Auguſt muſt be planted in frames or under hand-glaſſes, to ſtand the winter for ſpring uſe, and an early ſummer crop ſhould now be tranſplanted into the places where they are to remain all winter; this may be done about the middle or latter end of this month; or as ſoon as the plants are fit.

Chooſe a light rich ſpot for theſe plants in a warm ſituation, and where it lies well to the ſun. Plant the lettuces about three inches diſtant each way; cloſe the earth extremely well about each, and take care that they are not planted too deep. Then put on a frame, and cover them with the lights in froſty or very wet and cold weather; by which means theſe may be ſaved, and will be ready to plant out in the ſpring, as a ſure ſubſtitute, in caſe thoſe which were planted in the open borders are killed; and if both ſucceed, they will ſupply the table in ſucceſſional order. You may plant ſome of theſe lettuces under bell or hand-glaſſes, where cauliflowers are planted; placing them round the outſide of the cauliflowers, next the ſides of the glaſſes, and in the ſpring muſt be tranſplanted into the open ground; or if not accommodated with frames and glaſſes, or hand-glaſſes, &c. ſufficiently for this purpoſe, you may plant them in a bed in a warm ſituation, and then place ſome hoops acroſs the bed, and cover them with mats occaſionally, in cold nights, or froſty and rainy weather.

Tranſplant Cauliflower Plants from the Nurſery Bed of September to ſtand the Winter. — In the laſt week in this month tranſplant finally ſome of the beſt cauliflower plants into a warm quarter of rich ground, under hand glaſſes, in rows four feet aſunder, where they are to remain to produce their heads early next ſummer, and if they all ſurvive the winter, then in the ſpring thin them, leaving only one or two of the ſtouteſt plants in a place. See *March.*

Let ſome good rotten dung be ſpread over the place, and then let the ground be dug one ſpade deep, and well broken, taking care to bury the dung regularly. The glaſſes are to be kept conſtantly and cloſe down over the plants, till they have taken good root, which will be effected in about a week or ten days; then raiſe them on props, ſuch as brick-bats, or pieces of wood or ſtone, about three inches thick; and with theſe raiſe the glaſſes. In this manner the glaſſes are to remain night and day, except in froſty weather, when they muſt be let down quite cloſe; but if the months of November and December prove mild and dry, and the plants are much on the growing order, it will be proper to ſet the glaſſes off in fine dry days; obſerve to attend duly to this caution all the cold months. But if you are not provided ſufficiently with hand or bell glaſſes, or frames, you may plant ſome cauliflower plants out for good on a warm border, where they will ſometimes ſurvive the winter, and produce good heads. Or, for want of frames or any ſort of garden glaſſes, we often preſerve cauliflower plants through the winter in a bed of common earth, covered occaſionally with garden mats; the bed being in a warm ſituation, and arched over with hoops, and covered with mats in bad weather; ſuch as in time of hard rains, froſty or ſnowy weather: prick them out three or four inches aſunder, and plant out finally in the ſpring.

Winter dreſſing of Aſparagus Beds.—Any time in this month cut down the aſparagus ſtalks, and dreſs the beds. Let the ſtalks or haum be cut down cloſe to the ſurface of the beds; carry them immediately off the ground; then with a ſharp hoe, cut up all the weeds, and draw them off the beds into the alleys, then ſpread a little earth over the beds as you advance in your digging; the alleys ſhould be all of an equal depth, and the ſurface of the beds be left even and regular. But as old aſparagus beds will need an augment of dung once in two or three years, and that when deſigned to aſſiſt them with it, this is the time; but the manure or dung muſt be applied before the alleys are digged or the beds landed up. The dung for that purpoſe muſt be very rotten, and none is more proper than the dung of old cucumber or melon beds. When the aſparagus beds have thus had their winter dreſſing, there may be planted in each alley a row of coleworts, or cabbage plants; ſet the plants ſix or eight inches diſtant in the row. In this ſituation ſuch plants will, even in ſevere winters, ſometimes ſurvive the froſt; when thoſe which are planted in an open or level ſpot are deſtroyed. Or there may be planted in each valley a row of early garden beans.

Force Aſparagus for Winter Uſe.—Where forced aſparagus is required for uſe in winter, you may now begin to make hot beds for raiſing the firſt crop, for gathering in November and December; and for the method, ſee ***February***. If a conſtant ſucceſſion is required all winter and ſpring, a new hot-bed, planted with freſh plants, muſt be made every three or four weeks, from the beginning or middle of October, to the end of February or March; which will furniſh a conſtant ſupply of aſparagus from November till the arrival of the natural crops in the open ground, in April or May.

NOVEMBER.—*FRUIT GARDEN.*

Preparations for Plantations of Fruit-Trees.—If you intend to make new plantations of fruit trees, either for the wall or for eſpaliers, the borders ſhould be trenched two ſpades deep: but previouſly, if the ſoil is poor, or very light, and wants augmentation, add a ſupply of freſh ſtrong earth or compoſt, a good loamy earth, if it can be obtained, and rotten dung, working the whole together; but if only a few trees are wanted at different places, this work need not be performed but on ſuch places where the trees are to be planted, in a ſpace of from three or four to five or ſix feet width for each tree. If an orchard is to be planted, and the ſoil is but indifferent, it will be of advantage to add ſome very rotten dung, and freſh loam, or any good earth or compoſt the moſt eaſily obtained, in each hole where the trees are to ſtand; working the earth, loam and dung well together.

General Directions for Planting and Tranſplanting.—Obſerve, that the beginning of this month is the moſt eligible ſeaſon for planting and tranſplanting moſt ſorts of fruit-trees. In procuring them for planting, it is of conſiderable importance to have them taken up with their full ſpread of roots, all as entire as poſſible. In planting any kind of fruit-trees, take care always to let a circular hole be opened for each tree, a ſpade deep, and wide enough to let the roots ſpread freely and equally every way, and let the bottom of the holes be always well looſened. Likewiſe obſerve to let the roots of the trees be always pruned where needful; that is, cut off only any broken parts, and trim the ends of very long ſtraggling roots in general, for this makes them more freely produce new fibres. Likewiſe prune any irregular and croſs-placed ſhoots and branches of the head, and reduce within bounds any very long ſtragglers and very crouded wood, leaving the eligible branches in regular order. The next caution is, never to plant a tree too deep; never let the upper part of the roots be more than from three or four to five or ſix inches below the common ſurface of the ground. And in planting the tree, take good care to place it upright in the hole, and let the earth be well broken, and throw it in equally about all the roots, and at the ſame time ſhaking the tree gently, to cauſe the earth to fall in cloſe among the roots and fibres: when the hole is filled up, let the ſurface of the earth be gently trodden round the tree.

Plant Wall and Eſpalier Fruit-Trees.—Plant fruit trees, where required, in open weather, of any ſorts intended, both for walls, eſpaliers, and ſtandards; for wall trees, the ſorts are apricots, peaches, nectarines, plums, cherries, pears, vines, figs; for eſpaliers, apples, pears, plums, quinces, cherries; and for ſtandards, the principal ſorts are apples, pears, plums, cherries; with ſmaller portions of quinces, medlars, mulberries, filberts, ſervices, &c. Let the wall and eſpalier trees be planted fifteen feet aſunder, at leaſt, but if eighteen or twenty it will prove of conſiderable advantage, by admitting of a larger ſcope for the horizontal extenſion of the branches; it is often the caſe in gardens, where the trees have been planted too cloſe, that the trees meet and confuſe one another; though ſometimes they have not been planted above ſix or ſeven years. This is a great error, and ſhould be thought of when you are about to plant the trees. The diſtance which ſhould be allowed to peaches, nectarines, and apricots, is at leaſt fifteen or ſixteen feet from tree to tree; though eighteen or twenty will not be too much, yet the former diſtance will do very well. Plums and cherries ſhould be allowed the ſame room to run, though plums will require rather more room than cherries. By having theſe trees in eſpaliers, and againſt walls, their fruit is greatly improved in ſize, beauty and flavour; though apples are rarely indulged with a wall, but all the others are planted as wall and eſpalier-trees. Where the above trees are to be planted againſt walls or eſpaliers, we muſt repeat the caution, to allow them proper room; for this has been often forgot in making new plantations; and we very often ſee them planted ſo cloſe together, as would induce one to think, that the perſon who planted them never entertained a thought of their growing any larger; for by the time the trees begin to bear tolerably, they have met, incumbered, and ſtarved one another.

Plant Standard Fruit-trees.—Standard apples, and other fruit-trees of all ſorts, may alſo be planted any time this month, in mild weather. Where a plantation of ſtandard trees is to be made, either in the garden, or for an orchard, the trees ſhould be ſet at the diſtance of from twenty-five to thirty or forty feet every way from one another; but fifty or ſixty feet is more adviſeable, if for a continued full plantation in orchards; though ſtandards of ſmall or moderate growth may be planted at half that diſtance.

Plant Mulberry-trees, Medlars, and Quinces.—Mulberry, medlar, and quince-trees, may now be ſafely tranſplanted.

The mulberry-trees are moſt commonly planted, and trained for ſtandards; a few trees of them is ſufficient for the ſervice of a family or for variety; but to have earlier and larger fruit, you may alſo plant ſome for walls and eſpaliers. There are two ſorts, the black and the white fruited, but the black is the ſort to cultivate for general ſupply. Medlars may either be planted for ſtandards, or for eſpaliers; but by the latter, the fruit is generally much larger. Quinces ſucceed very well in ſtandards, but they are alſo ſometimes planted in eſpaliers, to form a variety among other fruit-trees trained in that order.

Plant Raſpberries.—This is a good ſeaſon to plant raſpberries, where a new plantation is wanted. Obſerve, it is the young ſhoots or ſuckers which ariſe every ſummer from the old roots that are the proper plants for the propagation of them, and for a freſh plantation. Theſe ſhrubs ſhould be planted in an open ſituation, and where the ground is good; and if you dig in ſome very rotten dung, it will be an advantage to the plants. In chooſing the plants for this plantation, obſerve to take ſuch as are well furniſhed with roots, for that is a principal article in raſpberry plants; and if there be one, two, or more buds formed on the root for next ſummer ſhoots, ſuch plants are particularly to be choſen. Having procured the plants, ſhorten the ſhoots a little, and leave only one ſtrong ſhoot on each root; let the ends of the roots alſo be trimmed: then put in the plants in rows four or five feet diſtant, and let them be planted a yard diſtant from one another in the row.

Plant Filbert-trees.—Now is a good time to plant filbert-trees and it is alſo a proper time to plant thoſe of the hazle-nut, and others of that kind, where ſuch plants are wanted. All theſe trees will thrive in almoſt any ſituation where it is not too wet in winter: they are principally raiſed by ſuckers from the root, or by layers of the young branches, to continue the deſirable varieties permanent in their kind; or by grafting in the ſpring: they being apt to vary when raiſed from the nuts. The trees ſhould be planted in rows, allowing twelve or fifteen feet between plant and plant in the row, and the rows ſhould be not leſs than twenty feet diſtant, and may train them to a ſingle ſtem of three, four, five, or ſix feet, and permitted to branch out above with full heads, according to their natural order of growth.

Plant Walnut-trees and Cheſnuts.—Now plant walnut-trees, and it is alſo a good ſeaſon to plant cheſnuts. Theſe trees are more fit to be planted in parks, orchards, or other open places, than in gardens, eſpecially in any conſiderable quantity: ſet theſe trees at leaſt thirty or forty feet diſtant from one another. Walnuts, in particular, are profitable to plant in large premiſes: their fruit is always very ſaleable in the markets, &c.

Plant Gooſeberry and Currant Trees.—Plant gooſeberry and currant trees where wanted. This ſhould be done about the middle of this month. Where it is intended to plant theſe ſhrubs in a full plantation by themſelves, mind to allow them proper room. Let them be planted in rows eight or ten feet diſtant, and allow at leaſt ſix feet between plant and plant in the row. At this diſtance you have room to dig and hoe between the trees, and alſo to prune them, and gather the fruit; and at this diſtance the berries will grow large, and will ripen freely; and there will alſo be room to plant or ſow many ſorts of kitchen plants between them. But if you intend to plant theſe ſhrubs in ſingle rows round the quarters of the kitchen-garden (as is commonly practiſed) you ſhould plant them full ſeven feet diſtant from each other. Alſo, if they are to be planted to divide the kitchen-ground into wide compartments of thirty or forty feet width and more, you ſhould ſet them about eight or ten feet diſtance in the row.

Propagate Gooſebetries and Currant Trees. — Plants cuttings and ſuckers of gooſberries and currants: this is an expeditious and plenteous method of propagating theſe ſhrubs. The proper cuttings for planting muſt be ſhoots of the laſt ſummer's production. Let them be taken from healthy trees, and ſuch as are remarkable, according to their kinds, for bearing the fineſt fruit: having procured ſuch cuttings, let each be ſhortened from about ten to twelve, or fifteen to eighteen inches long, according to its ſtrength, and plant them in a ſhady border. Let them be planted in rows croſsways the border, allowing ten or twelve inches between row and row, and put every cutting one third or near half way into the earth. Theſe ſhrubs may alſo be propagated by ſuckers from the root; which may now be taken up with roots, and planted; the ſtrongeſt at once where they are to remain, and the reſt in nurſery rows, for a year or two, &c. But ſome object to ſuckers, contending that they never produce ſuch large fruit as thoſe raiſed by cuttings, and are apt to run very much to wood; there is however no very material difference; and ſuckers being ready rooted, ſometimes of two or three years advance in growth, it is the moſt expeditious method. However, good cuttings may be preferred, and treat them as above; they will be well rooted in one year, and in the third will bear fruit.

Protecting Roots from Froſt and ſupporting new-planted Trees. — If the weather ſhould now prove ſevere, it will be proper to protect the roots of new-planted fruit-trees from being hurt by the froſt, by laying mulch, or long litter, on the ſurface of the ground, particularly the choiceſt of the ſtone-fruit kinds. Support all new planted ſtandard trees with ſtakes, and let a hay-band be put round the ſtem of the tree, at the place where it is to be faſtened to the ſtake, to prevent the bark from being galled.

NOVEMBER. — *KITCHEN GARDEN.*

Small Sallad, for Winter's Supply. — Sow the different ſorts of ſmall ſallading every ten or twelve days, that the table may be duly ſupplied with them. The ſorts are creſſes, muſtard, radiſh, rape, and lettuce. Where it was not done laſt month, and a ſupply of theſe ſmall herbs are required to be forwarded as ſoon as poſſible, it is eligible to make a ſlender hot-bed at this ſeaſon for raiſing them. The ſeed may either be ſown in drills, or all over the ſurface, and covered not more than a quarter of an inch deep with earth; or theſe ſeeds, at this ſeaſon, ſhould be but juſt covered. See *March.*

Tie up Endive, to Blanch. — Take the advantage of a dry day, to tie up ſome endive to whiten them. Chooſe for this purpoſe ſome of the beſt full-grown plants; and when their leaves are perfectly dry, let them be gathered up regularly in your hand, and tied together with a ſtring of baſs, or ſmall oſier twig. But if the weather is inclinable to be froſty or very wet, let the following method be practiſed to whiten ſome endive; lay them in a dry airy place for a day or two, to drain off the wet from between their leaves, and lay ſome earth in any dry open ſhed; raiſing the earth in a high ridge, and ſo lay the endive therein; obſerving in time of hard froſt to cover it with ſtraw. By the above method, you may whiten endive in any of the winter months, provided you take care to lay in a ſufficient quantity at the approach of ſevere weather. You may alſo practiſe the following method: in a ſouth border, or other warm dry ſituation in the full ſun, dig ſome of the ground in broad high ridges, making the ſides ſteep for the wet to run off: and into the ſides of this may depoſit the endive. For this purpoſe, let ſome endive plants be tied up as above directed, and inſert them into the ſide of the ridge of earth horizontally, almoſt to the top of their leaves. Thus the endive in this ridge of earth will blanch tolerably well, without much hazard of its rotting by rain. If the ridge is made high and ſteep, wet cannot lodge. But theſe plants, in ſuch ridges, ſhould be ſheltered in ſevere froſts by a covering of ſome dry long litter.

Earth up Artichokes. — About the middle or towards the latter end of this month, it will be time to cut down the leaves of artichokes, and earth up the plants to protect them from ſevere froſts. Let the trenches be dug out a good ſpade deep, and lay the earth as you dig it out ridge-ways, in a gradual rounding manner, over the rows of plants, obſerving to cover the crowns of them at leaſt ſix inches thick, leaving only the central leaves or heart of the plants uncovered, and drawing the earth cloſe about them; but at the approach of hard froſts let them be alſo covered with long litter; likewiſe in ſevere weather fill the trenches with very long dry litter, to prevent the froſt entering that way to the roots, &c.

Gather and Preſerve Carrots, Parſnips, Beet, &c. — The beginning of this month you ſhould take up carrots and parſnips, or other kitchen roots, in order to lay them in ſand, to preſerve them for winter uſe. If thoſe roots were to be permitted to remain in the ground, they would canker and rot, particularly the carrots; beſides, if ſevere froſt ſhould ſet in, the ground will be frozen ſo hard that it would be difficult to take the roots up at the time they are wanted. It is therefore proper to take up all the main crops of carrots, and a portion of the parſnips; the reſt may remain in the ground, as theſe are not ſo liable to ſpoil as the carrots. Then lay a bed of dry ſand on the floor about two or three inches thick; place the roots upon the ſand cloſe together, with the crowns outwards. Cover the roots with ſand two inches thick, then lay ſome more roots on that, and then more ſand, and ſo proceed with a layer of ſand and another of roots, till you have laid them all, and lay ſome ſtraw over the whole. Likewiſe dig up ſome red beet roots, to preſerve in the ſame manner; alſo ſalſafy, ſcorzonera, horſe-radiſh turnips, black turnip radiſh, &c. laying them in ſand as the carrots and parſnips.

Potatoes. — Where potatoes ſtill remain in the ground, let them now be taken up as ſoon as poſſible, before ſevere froſt begins; theſe roots cannot bear much froſt, for ſuch as are affected by it, immediately turn very watery, and then are not fit to eat. They ſhould be digged up with a flat three tyned fork, there being proper potatoe-forks for the purpoſe, made with flat tynes, blunted, roundiſh at the ends; in proceeding to dig up the potatoes, previouſly cut down the haulm or ſtalks of the plants near the ground, the remaining part of the ſtalks will ſerve as a direction in pitching the fork; then in digging up the potatoes, turn them clean up to the top, and collect them into baſkets, &c. Let theſe roots, when taken up, be well cleaned, and laid up in a dry apartment; and when the weather is ſevere, let them be covered with ſome dry ſtraw, and let this be laid almoſt a foot thick over them. Theſe roots, after being houſed, ſhould be from time to time looked over, and all ſuch as have any tendency to rotteneſs ſhould be taken out; for ſuch would infect thoſe that are ſound, and the infection would ſoon ſpread. See *March.*

DECEMBER. — *FRUIT GARDEN.*

Management of Fruit-tree Borders. — Where any of the fruit-tree borders are poor, or of bad ſoil, or much exhauſted, and want manuring, or to be revived with an augment of freſh earth, this is now a very good time to do that work. For that purpoſe, get from a common or elſewhere, a quantity of good freſh loamy earth, if it can be had, (top ſpit), or in want of this, other ſubſtantial good ſoil, and ſome of the beſt thoroughly rotten dung, mixing both well together, Let this be laid upon the border, dug in, and well worked with the earth of the border. The ſooner this is done the better, for this dreſſing will be of great ſervice to the trees in general, as will be ſeen in a ſummer or two after, but particularly ſuch trees as are in a declining ſtate. The freſh earth, and the good rotten dung, will encourage the trees ſurpriſingly, ſo as to produce large fruit, and they will be fair and well taſted. Or borders of ordinary good ſoil may be continued in a fertile ſtate by application of dung only, once in two or three years. In open weather, dig and prepare ſuch borders, or other places as are to be planted with fruit-trees; for this being a leiſure time, that work can be done in a proper manner. In doing this work let thoſe rules be obſerved which we gave in the preceding month. If any of the wall trees appear of a weak or ſickly ſtate, open the earth about the extreme roots, but not to diſturb them generally, and then apply a compoſt of freſh loamy ſoil, or other good earth, and rotten dung, immediately next to the principal roots, and towards their extreme parts, it will greatly enliven the growth of the tree the following year.

Examine the Fruit in the Fruitery. — Examine the fruit in the fruitery now pretty often; let them be looked over with good attention once or twice every week: and let all ſuch as are rotten, or beginning to rot, be removed; for if theſe were permitted to lie, they would ſoon taint all the ſound fruit near them. Continue conſtantly a good covering of clean ſtraw, at leaſt a foot thick, over the fruit; and ſecure the windows of the fruit-room from the admiſſion of wet and froſt.

DECEMBER. — *KITCHEN GARDEN.*

Earth up Celery. — Take advantage of the firſt dry and mild day to earth up the celery that requires it; and ſee that the plants are firſt perfectly dry. Break the earth ſmall, and let it be laid up to the plants, with care not to break their leaves, or bury the hearts of the plants, for that would rot them. Obſerve, if poſſible, to earth up the plants within four or five inches of their tops, to guard them from the froſt, and to blanch them a good length. If ſevere froſty weather ſets in, it will be proper to cover ſome of your beſt celery plants for preſent uſe, with ſome long litter, or ſuch as peas ſtraw, fern, or the like.

Muſhrooms. — Now take good care of the muſhroom beds, to keep the froſt and wet from them. To do this, let a good covering of clean dry ſtraw be kept conſtantly over every bed, not leſs than a foot in thickneſs. After heavy rains or ſnow, let the beds be examined, and if you find the covering next the bed wet, let the wet ſtraw be directly removed, and ſome dry be laid in its place. For the general management of theſe beds, ſee *September.*

Manure and Trench Kitchen-ground. — Now take advantage of dry days and froſty weather, and bring in rotten dung from old hot beds, or from dung-hills, and lay it upon ſuch vacant pieces of kitchen ground as want manure. Likewiſe now dig or trench up all ſuch pieces of ground as are vacant; and, in order that the ground may receive the true advantage of fallow, let every piece, as you dig or trench it, be laid up in narrow ridges. The method of ridging up the ground in winter ſhould be practiſed in every ſoil and ſituation, it being of great advantage: this will improve the ground more than many could imagine; for by its being laid up in rough ridges, the froſt, ſun and air, can then have more free acceſs; all of which contribute greatly to the enriching and mellowing the ground; and the ſooner this is done the better. Let the ridges be digged generally two full ſpades broad, and one or two deep, and lay them up rough, and as high and ſharp as they will ſtand. By digging the vacant pieces of ground in the winter ſeaſon, it is not only an advantage to the ſoil, but it alſo looks neat, and will greatly forward

ward the buſineſs in the ſpring, when there is always much other work in hand.

Culture of Pines in the Hot Houſe. — Theſe plants are propagated by planting the crowns or ſuckers: theſe, after having been laid to dry in a warm place four or five days, are to be ſet in pots of five or ſix inches over at the top, filled with good freſh light earth, mixed with a little rotten dung; this mixture muſt be often turned, for eight or twelve months, to make it mix the more perfectly. The moſt proper compoſt mould for the pine plant, ſays Mr. Speechly, is prepared by paring off the turf of a paſture, where the ſoil is a ſtrong rich loam, and of a reddiſh colour, about two inches thick; and laying it with the graſs ſide downwards, and one courſe thick in the pens of ſheep-paſtures, where it may continue two, three, or more months, being enriched by their urine and dung, and reduced by the treading of their feet. When it has lain in the pens till the quantity of ſheep's dung conſtitutes about one third part, it may be laid in a heap for at leaſt ſix months, being often turned in that time: three wheel barrows of this ſoil, one barrow of vegetable mould from decayed oak-leaves, and half a barrow of coarſe ſand, make a compoſt mould for crowns, ſuckers, and young plants. Three wheel barrows of the above ſwarth, two barrows of vegetable mould, one of coarſe ſand, and one fourth of a barrow of ſoot, make a compoſt mould for fruiting plants. The plants, when ſet, muſt have a little water, to ſettle the earth about their roots; and the pot then plunged into a well-tempered bed of tanner's bark.

In the ſummer ſeaſon they ſhould be gently watered about twice in a week; and once a week over their leaves, in order to waſh the filth from them, and to promote the growth of the plants. Some perſons frequently ſhift their plants from pot to pot; but it is not adviſeable to remove them oftener than twice in a ſeaſon; firſt about the end of April, and again in the beginning of Auguſt. At each of theſe times the bark-bed ſhould be ſtirred, and new bark added; and the plants, when they are plunged into it, ſhould be gently watered over their leaves. Here they may remain till the beginning of November; and in the winter ſeaſon they ſhould not be watered more than once a week. Thoſe plants which ſhew their fruit ſhould never be removed; becauſe ſhifting them at this period will ſtint their growth, and retard their ripening. In winter the heat of the ſtove is regulated by a thermometer, which ſhould never be kept to a greater warmth than five or ſix diviſions above ananas, nor ſuffered to be more than as many diviſions below it. In winter they will require watering only once a week. When the plants are placed into the tan for the winter ſeaſon, which ſhould be done about the beginning of October, the tan-bed ſhould be renewed, adding two-thirds of new tan to one third of the old, which will maintain a proper degree of warmth till February, when it ſhould be ſtirred again, and a load or two of new tan added, ſo as to raiſe the bed as much as it ſunk ſince the autumn. In April it will be proper to ſtir up the tan again; and by adding freſh tan, to renew the warmth of the bed, and forward the fruit. At this time it will be proper to ſhift the young plants, which are deſigned to produce fruit the following year; and the tan-bed into which theſe are plunged, muſt be renewed, in order to forward their growth, that they may have ſtrength enough by autumn to produce good fruit.

Thoſe plants, which ſhew their fruit early in February, will ripen about June; but the ſeaſon in which the fruit is in greateſt perfection is from the beginning of May, to the end of September. The method of judging when the fruit is ripe is by the ſmell and from obſervation; nor ſhould it remain ſo long before it is cut as to become ſoft to the touch, for it will become flat and dead; and it ſhould be cut early in the morning, laid in a cool but dry place, preſerving the ſtalk and crown upon it, and eaten the ſame day in which it is cut. That ſort with green fruit, if ſuffered to ripen well, is of an olive-colour; but the ſugar-loaf ſort is perferable, and is eaſily diſtinguiſhed from all the others by the purple ſtripes on the inſide of its leaves. The fruit, when ripe, is of a paler colour than the others. This ſort was brought from Braſil to Jamaica. The next in goodneſs to this is the Montſerrat *pine*.

One of the principal difficulties attending the culture of the *pine-apple* has been to deſtroy the inſects which infeſt it. Mr. Speechley, in a late treatiſe on this ſubject, has enumerated three ſpecies, viz. the brown turtle inſect, or *coccus heſperidum* of Linnæus; the white ſcaly inſect; and the white mealy crimſon-tinged inſect. The methods that have been formerly in uſe for extirpating them have been to ſhift the plants into freſh pots, at the ſame time cleanſing their leaves, and roots, which is uſually denominated a dreſſing. Decoctions made from tobacco, wormwood, walnut leaves, henbane, and other herbs of a bitter and poiſonous quality, have alſo been generally uſed on this occaſion, to which ſome have added ſnuff, ſulphur, and pepper; but none of theſe are in their nature ſufficiently penetrating.

He recommends the following receipt: take one pound of quickſilver; put it into a glazed veſſel, with one gallon of boiling water; let it ſtand till it becomes cold, and pour off the water for uſe. Repeat this on the ſame quickſilver, till a ſufficient number of gallons is provided; then to every gallon of this mercurial water add ſix ounces of ſoft green ſoap, diſſolved in a portion of it; let the mixture be milk-warm when it is uſed; then tie the leaves of the large ſized plants together; take them out of the pots, and diveſt them of their leaves, and dip them wholly in the mixture for three minutes, and ſet them out in the open air to dry, with their roots downwards; in a few hours repeat the operation a ſecond time, having added one table-ſpoonful of ſweet oil to every gallon of the mixture; then ſet them to dry with their tops downwards, and afterwards remove them to the hot houſe. The moſt eligible ſeaſons are March and September. The ſame author has alſo deſcribed a method of raiſing pines without the uſe of tanner's bark, or, at moſt, with only a covering of tan two inches thick, viz. by oak-leaves, collected in the fall of the year, laid in heaps ſix or ſeven feet thick to couch, well trodden, and occaſionally moiſtened, for five or ſix weeks, which, he ſays, are ſuperior to bark for this uſe. See Dr. Hunter's Edition of Evelin's Sylva, 1776. A ſimilar idea of uſing the decayed leaves of trees in the hot-houſe was before ſuggeſted by Mr. Clark of Chiſwick, and applied to the culture of melons. It appears that leaves under proper management, i. e. after fermentation, &c. are a moſt valuable manure; mixed with dung they make the beſt hot-beds, which preſerve their heat much longer than thoſe which are made entirely with dung. Beſides, when reduced to black vegetable mould, and mixed with compoſt of earth, they are ſuperior to every other for flowers, as well as for all plants that grow in pots. Of late, ſome very conſiderable improvements have been made in the culture of pines. The leaves of the oak have been ſubſtituted for the more expenſive bark; and by treating the pines with them, they are found to thrive as well, and to produce as good fruit, as in the other method; and of the proper way of managing theſe leaves for the rearing of exotic plants, an account is given under the article OAK *Leaves*. But the moſt conſiderable improvement is that mentioned in the 67th volume of the Philoſophical Tranſactions, where a method is ſhown by William Baſtard, Eſq; of Devonſhire, of raiſing theſe fruits in water. The plant contained in a pot of earth is placed in a pan, which is always kept full of water, and which ſtands on a ſhelf near the higheſt, and conſequently the moſt heated, part of the back wall of the hot houſe, ſo that the *pine* plants ſtand as near as poſſible to the glaſs, without abſolutely touching it. The fruit raiſed in this manner is ſaid to be always much larger as well as better flavoured, than when it is ripened in a bark-bed. Mr. Baſtard obſerves, that, as a perſon was moving a large pine-plant from the hot bed in his houſe, which was juſt ſhowing fruit, by ſome accident he broke off the plant juſt above the earth in which it grew, and there was no root whatever left to it: by way of experiment he took the plant, and fixed it upright in a pan of water (without earth) on the ſhelf; it ſoon threw out roots, and bore a pine apple that weighed more than two pounds.

The firſt Article in this Treatiſe which deſcribes the conſtituent parts of the ſcenes of nature; and the ſecond which illuſtrates thoſe properties in the objects of nature that ſhould determine the choice and management of them in Gardening; are extracted from a very valuable Work, and abridged to a fourth of its original compaſs, by ſelecting the moſt beautiful and eſſential paſſages.

Though theſe Articles occupy two ſheets in this work, it is preſumed not one of the ſubſcribers would wiſh they had been comprized in leſs, as they abound with ſuch beautiful ideas, pictureſque diſplays, and judicious remarks.

With reſpect to the other parts of this Treatiſe, which contain the Flower, Fruit, and Kitchen Gardens, I hold myſelf indebted in ſome inſtances to other works which have treated on theſe ſubjects in a general point of view; and cannot but in juſtice acknowledge, they poſſeſs great merit, and exhibit evident traits of practical and experimental knowledge.

The only objection that can be made to them is their tedious prolixity and uſeleſs repetition; therefore, where I have had occaſion to conſult them, I have pruned them of their excreſcencies, and lopped off their ſuperfluities; by which means I have been able, in this limited ſpace, to comprize all the eſſential principles of gardening.

In my directions for the management of the Kitchen Garden, I have particularly attended to the early and late crops, and have been infinitely more copious on them than I have been on the general crops; becauſe the former require much more care and attention, being in a great meaſure dependent upon art; while the latter need but little direction; being forwarded by the ſpontaneous efforts of nature. Beſides, the produce of the early and late crops is more acceptable to private families, as affording a ſupply of articles which are rare and not to be purchaſed without conſiderable expence; while that of the general crops may be cultivated with little direction or trouble, or purchaſed at a trifling charge. And though the early and late crops do not yield ſo abundantly as the general, their ſcarcity and value amply compenſate for their deficiency.

I have not entered into the general buſineſs of the hot-houſe, but have confined my directions to the culture of the Pine; being the moſt rare and delicate of its productions; and as it is an article which comes within the concern of but few, I have omitted it, as it would lead too far beyond the œconomy of this publication.

Thoſe Noblemen and Gentlemen who wiſh to be furniſhed with any of the Articles requiſite for putting into execution the different practices here recommended, may be ſupplied from my Nurſery; where all orders will be duly attended to.

HOXTON FIELD NURSERY. JOHN RENTON.

GARGARISM, Gargle, in medicine, a liquid form of remedy, for diſorders in the mouth, gums, throat, &c. Gargariſms are compoſed of honey, ſalt, ſyrups, ſpirits, vinegar, waters, and decoctions; and produce their effects by cleanſing, lubricating, &c. the parts.

GARLAND, an ornament for the head, made in manner of a crown or chaplet. Garlands denote ornaments of flowers, fruits, and leaves, intermixed; anciently much uſed at the gates of temples, where feaſts or ſolemn rejoicings were held; or at any other places where marks of public joy and gaiety were deſired; as at triumphal arches, tournaments, &c. Garlands or feſtoons were alſo put on the heads of victims, in the ancient heathen ſacrifices.

GARLICK, in botany. See Allium.

GARNET, in natural hiſtory. See Granate.

GARNISHING is generally uſed for the furniture, aſſemblage, or ſortment, neceſſary for the uſing or adorning any thing. The word is French, formed of the verb *garnir, to furniſh*, or *fit out*. The garniſhing of a diſh conſiſts of certain things which accompany it, either as a part and ingredient thereof; in which ſenſe pickles, muſhrooms, oyſters, &c. are garniſhing: or as a circumſtance, or ornament; as when leaves, flowers, roots, &c. are laid about a ſervice to amuſe the eye.

GARRISON, in the art of war, a body of forces diſpoſed in a fortreſs, to defend it againſt the enemy, or to keep the inhabitants in ſubjection, or even to be ſubſiſted during the winter ſeaſon. Garriſon, and winter quarters, are ſometimes uſed indifferently for the ſame thing; and ſometimes they denote different things. In the latter caſe, a garriſon is a place wherein forces are maintained to ſecure it, and where they keep regular guards; as, a frontier town, a citadel, caſtle, tower, &c.

GARTER, a ligature to keep up the ſtockings, it is alſo particularly uſed for the badge or cognizance of a noble order of knights, hence denominated the

Order of the Garter, a military order, next in dignity after the nobility, inſtituted by king Edward III. in 1344, under the title of the *ſovereign* and *knights companions of the moſt noble order of the garter*. For a particular deſcription of the order of Bath, the order of the Thiſtle, and the order of St. Patrick, with their jewels and appendages, ſee Knighthood.

Garter *principal King at Arms*. This office was inſtituted by Henry V. *Garter* and *principal king at arms*, are two diſtinct offices united in one perſon; *Garter*'s employment is to attend the ſervice of the order of the *garter*; for which he is allowed a mantle and badge, a houſe in Windſor-caſtle, and penſions both from the ſovereign and knights, and laſtly, fees. He alſo carries the rod and ſceptre at every feaſt of St. George, when the Sovereign is preſent, and notifies the election of ſuch as are new choſen; attends the ſolemnity of their inſtallations, and takes care of placing their arms over their ſeats; and carries the *garter* to foreign kings and princes, for which ſervice it has been uſual to join him in commiſſion with ſome peer, or other perſon of diſtinction. *Garter*'s oath relates only to ſervices being performed within the order, and is taken in chapter before the ſovereign and knights. His oath, as king at arms, is taken before the earl marſhal.

Garter is alſo a term in heraldry, ſignifying the moiety, or half of a bend.

GAS, in chymiſtry, is a name given to the volatile inviſible parts which eſcape from certain bodies, and which cannot be retained and collected, at leaſt without great difficulty and mixture of other ſubſtances. The word is applied by Van Helmont to ſignify thoſe elaſtic fluids which are inviſible, and not condenſable by cold; ſeveral of which he has deſcribed: ſuch are the *gas ventoſum*, or atmoſpherical air; *gas ſylveſtre*, or the fluid expelled during fermentations and effervescences, called by later authors, fixed, factitious, and fixable air; *gas pingue*, or the fluid extricated from inflammable ſubſtances during their analyſis by heat; *gas flammeum*, or the fluid produced in the deflagration of nitre. For a particular definition of theſe ſeveral kinds of air, ſee the Syſtem of Aerology.

GASCONADE, a boaſt or vaunt of ſomething very improbable. The term has its riſe from the Gaſcoons, or people of Gaſcony, in France, who, it ſeems, have been diſtinguiſhed for bragging and rhodomontado.

GASTEROSTEUS, the stickle-back, in ichthyology, a genus of fiſhes belonging to the order of thoracici. There are three rays in the membrane of the gills; the body is carinated: and there are ſome diſtinct prickles before the back-fin. There are 11 ſpecies diſtinguiſhed by the number of prickles on the back. In the fens of Lincolnſhire, and ſome rivers that proceed from them they are found in prodigious quantities. At Spalding there are once in ſeven or eight years, amazing ſhoals that appear in the Welland, and come up the river in form of a vaſt column. They are ſuppoſed to be the multitudes that have been waſhed out of the fens by the floods of ſeveral years, and collected in ſome deep hole, till, overcharged with numbers, they are periodically obliged to attempt a change of place. The quantity is ſo great, that they are uſed to manure the land. A notion may be had of this vaſt ſhoal, by being informed, that a man being employed by the farmer to take them, has got for a conſiderable time four ſhillings a-day by ſelling them for a halfpenny per buſhel. This ſpecies ſeldom reaches the length of two inches; it hath three ſharp ſpines on the back, that can be raiſed or depreſſed at pleaſure. The colour of the back and ſides is an olive-green; the belly white; but in ſome the lower jaws and belly are of a bright crimſon.

GASTRIC, Gastricus, in anatomy, is applied to divers veins, on account of their proceeding from the ſtomach or ventricle, which the Greeks call γαςηρ. The *gaſtricus major*, or greater *gaſtric* vein, is inſerted into the ſplenic vein; and the *minor*, or leſſer *gaſtric* into the trunk of the vena porta.

Gastric *Juice*, a name given by ſome authors to the proper juice of the ſtomach. This is a thin pellucid ſpumous, and ſaltiſh liquor, which continually diſtils from the glandulous kernels of the ſtomach, for the diſſolution, mixture, and dilution of our food, and is of great ſervice in digeſtion.

GASTROCNEMIUS, from γαςηρ, and κνημη the *leg*, in anatomy, a name common to two muſcles, conſtituting the ſura, or calf of the leg; the one called *externus*, and the other *internus*. For theirorigin, inſertion, and uſe, ſee Syſtem of Anatomy, Sect. XIII. For their repreſentation, ſee Plate III, *fig*. 2, Letters *k* and *l*.

GAVEL, or Gabel, in law, ſignifies tribute, toll, cuſtom, yearly rent, payment, or revenue, of which there where anciently ſeveral kinds; *gavel-corn, gavel-malt, out-gavel, gavel-fodder*, &c.

GAUGING, the art or act of meaſuring the capacities or contents of all kinds of veſſels, and determining the quantity of fluids, or other matters, contained therein. See Mensuration.

GAWSE, or Gawze, in commerce, a very thin, ſlight, tranſparent kind of ſtuff, woven ſometimes of ſilk, and ſometimes only of thread.

GAZELLA, Gazelle, or Antelope, is a ſpecies of the *capra*, or *goat*, in the Linnæan ſyſtem; others have made it a diſtinct genus, with annulated, or twiſted horns, eight broad cutting teeth in the lower jaw, and body and limbs of a light elegant form. Thus, they make it an intermediate genus between the *goat* and *deer*, agreeing with the firſt in the texture of their horns, which have a core in them, and they never caſt them, and with the laſt in the elegance of their form and great ſwiftneſs. The agility and ſpeed of this animal are ſurpriſing, ſo that the chace of it is a favourite diverſion in the eaſtern nations. Some ſpecies of the antelope form herds of two or three thouſand, while others keep in ſmall troops of five or ſix. There are ſeveral ſpecies and varieties of this animal, which, excepting two or three, inhabit the hotteſt part of the globe. Their proper climates ſeem to be thoſe of Aſia and Africa, where they are very numerous.

GAZETTE, a news-paper, or printed account of the tranſactions of divers countries.

GEHENNA, Γεεννα, a ſcripture term, which has given ſome pain to the critics. It occurs in St. Matthew v. 22. 29. 30. x. 28. xviii. 9. xxiii. 15. 33. Mark ix. 43. 45. 47. Luke xii. 5. James iii. 6. The authors of the Louvain and Geneva verſions retain the word *gehenna*, as it ſtands in the Greek; the Engliſh tranſlators render it by *hell* and *hell-fire*; and the like do the tranſlators of Mons, and father Bohours. The word is formed from the Hebrew *gehinnon*, i. e. valley of Hinnom. In that valley, which was near Jeruſalem, there was a place named *Tophet*, where ſome Jews ſacrificed their children to Moloch, by making them paſs through the fire. King Joſias, to render this place for ever abominable, made a cloaca or common-ſewer thereof, where all the filth and carcaſes in the city were caſt. The Jews obſerve farther, that there was a continual fire kept up there, to burn and conſume thoſe carcaſes; for which reaſon, as they had no proper term in their language to ſignify *hell*, they made uſe of that of *gehenna*, or *gehinnon*, to denote the fire unextinguiſhable.

GELATINOUS, among the phyſicians, is applied to any thing approaching the glutinous conſiſtence of a Jelly.

GELDING, the operation of caſtrating, and particularly horſes. The manner of gelding is thus: the beaſt being caſt on ſome ſoft place, the operator takes the teſticles between his fore and great finger; ſlits the cod, and preſſes out the ſtones; then taking a pair of nippers made very ſmooth, either of ſteel, box, or brazil, he claps the ſtrings of the ſtones between them, very near to where the ſtones are ſet on, and preſſes them ſo hard, that there may be no flux of the blood, and then ſears away the ſtone with a thin cauterizing iron, made red hot. This done, he takes a hard plaſter, made of wax, reſin and waſhed turpentine, melted together, and melts it on the head of the ſtrings with the hot iron, and afterwards ſeers the ſtrings, and melts more of the ſalve, till there is a good thickneſs of the ſalve laid on the ſtrings. This being done to the ſtones, the nippers are looſened, and the like is done to the other; and the two ſlits of the cod, are then filled with white ſalt, and the outſide of the cod anointed with hog's greaſe; and thus they let him riſe, and keep him in a warm ſtable, without tying him up. If he ſwells much in his cod or ſheath, they chaſe him up and down, and make him trot an hour in the day, and he ſoon recovers. See Castration and Eunuch.

GEM, in natural hiſtory, a common name for all precious ſtones; of which there are two claſſes, the pellucid, and ſemipellucid. The bodies compoſing the claſs of pellucid gems are bright, elegant, and beautiful foſſils, naturally and eſſentially compound, ever found in ſmall detached maſſes, extremely hard, pellucid, and of great luſtre; compoſed of a very firm and pure matter, without any admixture of earthy ſubſtance; giving fire with ſteel, not fermenting with acid menſtruums, and very difficultly calcinable in the fire. Of this claſs there are two genera; the chroſtaſima, and the chroaſtaces. See CHROSTASIMA and CHROASTACES.

The bodies compoſing the claſs of ſemipellucid gems, are ſtones naturally and eſſentially compound, not inflammable nor ſoluble in water, found in detached maſſes, and compoſed of cryſtalline mater, debaſed by earth: however, they are but ſlightly debaſed, and are of great beauty and brightneſs, of a moderate degree of tranſparency, and are uſually found in ſmall maſſes. Of this claſs there are two orders: the firſt of which conſiſts of the ſemipellucid gems, of but two variegations, and frequently of one plain ſimple colour; though ſometimes veined: this order contains four genera, viz. the ſardæ, the chalcedonies, the hydrophanæ, and the pramnion. See the articles SARDÆ, HYDROPHANÆ, and PRAMNION.

The ſecond order of ſemipellucid gems, conſiſting of thoſe remarkable for their veins, zones, and variegations, contains alſo four genera, viz. the achatæ, the onyches, the ſardonyches, and the camæa. See the articles ACHATÆ, ONYCHES, SARDONYCHES, and CAMÆA.

The knowledge of gems depends principally on obſerving their hardneſs and colour. Their hardneſs is commonly allowed to ſtand in the following order: the diamond the hardeſt of all: then the ruby, ſapphire, jacinth, emerald, amethyſt, garnet, carneol, chalcedony, onyx, jaſper, agate, porphyry, and marble. This difference, however, is not regular and conſtant, but frequently varies. Good cryſtals may be allowed to ſucceed the onyx; but the whole family of metallic glaſſy fluors ſeem to be ſtill ſofter. In point of colour, the diamond is valued for its tranſparency, the ruby for its purple, the ſapphire for its blue, the emerald for its green, the jacynth for its orange, the amethyſt carneol for its carnation, the onyx for its tawny, the jaſper, agate, and porphyry for their vermillion, green, and variegated colours, and the garnete for its tranſparent blood red.

All theſe gems are ſometimes found coloured and ſpotted, and ſometimes quite limpid and colourleſs. In this caſe the diamond-cutter or poliſher knows how to diſtinguiſh their different ſpecies by their different degrees of hardneſs upon the mill. For the cutting or poliſhing of gems, the fine powder of the fragments of thoſe that are next in degree of hardneſs is always required to grind away the ſofter; but as none of them are harder than the diamond, this can only be poliſhed by its own powder.

Imitation or Counterfeiting of GEMS *in Glaſs.*—The art of imitating gems in glaſs, is too conſiderable to be paſſed without notice: ſome of the leading compoſitions therein, we ſhall briefly mention upon the authority of Neri. Theſe gems are made of paſtes; and are no way inferior to the native ſtones, when carefully made and well poliſhed, in brightneſs or tranſparence, but want their hardneſs. The general rules to be obſerved in making the paſtes are theſe: 1. That all the veſſels in which they are made be firmly luted, and the lute left to dry before they are put into the fire. 2. That ſuch veſſels be choſen for the work, as will bear the fire well. 3. That the powders be prepared on a porphyry ſtone; not in a metal mortar, which would communicate a tinge to them. 4. That the juſt proportion in the quantity of the ſeveral ingredients be nicely obſerved. 5. That the materials be all well mixed; and if not ſufficiently baked the firſt time, to be committed to the fire again, without breaking the pot: for if this be not obſerved, they will be full of bliſters and air-bladders. 6. That a ſmall vacuity be always left at the top of the pot, to give room to the ſwelling of the ingredients.

To make paſte of extreme hardneſs, and capable of all the colours of the gems, with great luſtre and beauty: Take of prepared cryſtal, ten pounds; ſalt of polverine, ſix pounds; ſulphur of lead, two pounds; mix all theſe well together into a fine powder; make the whole with common water into a hard paſte; and make this paſte into ſmall cakes of about three ounces weight each, with a hole made in their middle; dry them in the ſun, and afterwards calcine them in the ſtraiteſt part of a potter's furnace. After this, powder them, and levigate them to a perfect fineneſs on a porphyry ſtone, and ſet this powder in pots in a glaſs furnace to purify for three days: then caſt the whole into water, and afterwards return it into the furnace, where let it ſtand 15 days, in which time all foulneſs and bliſters will diſappear, and the paſte will greatly reſemble the natural jewels. To give this the colour of the emerald, add to it braſs thrice calcined; for a ſea green, braſs ſimply calcined to a redneſs; for a ſapphire, add zaffer, with mangane[s]e and for a topaz, manganeſe and tartar. All the gems are thus imitated in this, by the ſame way of working as the making of coloured glaſſes; and this is ſo hard, that they very much approach the natural gems. The colour of all the counterfeit gems made of the ſeveral paſtes, may be made deeper or lighter, according to the work for which the ſtones are deſigned; and it is a neceſſary general rule, that ſmall ſtones for rings, &c. require a deeper colour, and large ones a paler. Beſides the colours made from manganeſe, verdigreaſe, and zaffer, which are the ingredients commonly uſed, there are other very fine ones which care and ſkill may prepare. Very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from braſs or copper; a ſky-colour from ſilver, and a much finer one from the granates of Bohemia.

GEMELLES, in heraldry, a bearing of bars by pairs, or in couples, in a coat of arms. He beareth gules, on a chevron argent, three bars *gemelles* ſable, by the name of Throgmorton.

GEMELLUS, in anatomy, a muſcle of the arm, called alſo Biceps extenſor cubiti. For its origin, inſertion, and uſe, ſee ſyſtem of ANATOMY, Sect. XIV. For repreſentation, ſee Plate III. *fig.* 1. Letter *b*.

GEMINI, in aſtronomy, the *twins*; a conſtellation, or ſign of the zodiac, the third in order, repreſenting Caſtor and Pollux: and it is marked thus, ♊. See ſyſtem of ASTRONOMY, Sect. IX.

GEMINI, in anatomy, two muſcles of the thigh, called alſo gemelli, for their origin, inſertion, and uſe, ſee ſyſtem of ANATOMY, Part III. Sect. XIII. for their repreſentation, ſee Plate III. *fig.* 2, Letters *k* and *n*.

GEMMA, or BUD, in botany; a compendium or epitome of a plant ſeated upon the ſtem and branches, and covered with ſcales, in order to defend the tender rudiments incloſed from cold and other external injuries, till, their parts being unfolded, they acquire ſtrength, and render any further protection unneceſſary. Buds, together with bulbs, which are a ſpecies of buds generally ſeated upon or near the root, conſtitute that part of the herb called by Linnæus *hybernacula*; that is, the winter-quarters of the future vegetable; a very proper appellation, as it is during that ſevere ſeaſon that the tender rudiments are protected in the manner juſt mentioned. Plants, conſidered in analogy to animals, may properly enough be reckoned both viviparous and oviparous. Seeds are the vegetable eggs; buds, living fœtuſes, or infant-plants, which renew the ſpecies as certainly as the ſeed. From the obvious uſes of the buds, we may collect the reaſon why the ſupreme author of nature has granted this ſort of protection to moſt of the trees that are natives of cold climates; and, on the other hand, denied it to ſuch as, enjoying a warm benign atmoſphere, have not the tender parts of their embryo-ſhoots expoſed to injuries and depredations from the ſeverities of the weather. As each bud contains the rudiments of a plant, and would, if ſeparated from its parent vegetable, become every way ſimilar to it; Linnæus, to ſhew the wonderful fertility of nature, has made a calculation, by which it appears, that, in a trunk ſcarce exceeding a ſpan in breadth, ten thouſand buds (that is, herbs) may be produced. What an infinite number then of plants might be raiſed from a very large tree.

GENDARMES, or GENS D'ARMES, in the French armies, a denomination given to a ſelect body of horſe, on account of their ſucceeding the ancient Gendarmes, who were thus called from their being completely clothed in armour; (ſee *Scots* GENDARMES *infra.*) Theſe troops are commanded by captain-lieutenants, the king and the princes of the blood being their captains; the king's troop, beſides a captain-lieutenant, has two ſub-lieutenants, three enſigns, and three guidons.

Grand GENDARMES, at preſent are a troop compoſed of 250 gentlemen; the king himſelf is their captain, and one of the firſt peers their captain-lieutenant, who has under him two lieutenants, three enſigns, three guidons, and other officers.

Small GENDARMERY, are, the Scots Gendarmes, the queen's, the dauphin's, the gendarmes of Anjou, Burgundy, the Engliſh and Flemiſh gendarmes, having each a captain-lieutenant, ſub-lieutenant, enſign, guidon, and quarter-maſter.

Scots GENDARMES, were originally inſtituted by Charles VII. of France, about the middle of the 5th century, and formed a part of his guard; in which ſtation alſo they acted under other princes. It was their prerogative to take precedence of all the companies of the gendarmerie of France; and, on particular occaſions, they even preceded the two companies of the king's mouſquetaires. The ſons of the Scottiſh monarchs were the uſual captains of this company; and, after Mary's acceſſion to the throne, its command belonged to them as a right. It was thence that James VI. made a claim of it for his ſon prince Henry. This honour, and its emoluments, were alſo enjoyed by Charles I. and the next in command to this prince was Louis Stuart duke of Lennox. George Gordon, Marquis of Huntley, ſucceeded the duke of Lennox in the year 1624, and took the title of captain or commander in chief when Charles I. mounted the Engliſh throne. It is not certain whether Charles II. was ever captain of this company; but it was conferred on his brother the duke of York, who was captain of the Scots gendarmes till the year 1667, when he reſigned his commiſſion into the hands of the French king. Since that time, no native of Great Britain has enjoyed this command.

GENDER, among grammarians, a diviſion of nouns, or names, to diſtinguiſh the two ſexes. This was the original intention of gender; but, afterwards, other words, which had no proper relation either to the one ſex or the other, had genders aſſigned them, rather out of caprice than reaſon; which is at length eſtabliſhed by cuſtom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor*, in Latin, is feminine; but *arbre*, in French, is maſculine; and *dens*, in Latin, is maſculine; but *dent*, in French, is feminine. The oriental languages frequently neglect the uſe of genders; and the Perſian language has none at all; which is no diſadvantage, the diſtinction of genders being in great meaſure uſeleſs.

The Latins, Greeks, &c. generally content themſelves, to expreſs the different genders by different terminations, as *bonus equus*, "a good horſe;" *bona equa*, "a good mare," &c. But in Engliſh, we frequently go further, and expreſs the difference of ſex by different words; as boar, ſow; boy, girl; buck, doe; bull, cow; cock, hen; dog, bitch; &c.—We have only about 24 feminines, diſtinguiſhed from the males, by the variation of the termination of the male into *eſs*: of which number are abbot, abbeſs; count, counteſs; actor, actreſs; heir, heireſs; prince, princeſs; &c. which is all that our language knows of any thing like genders. The eaſtern languages, as well as the vulgar languages of the weſt, have only two genders; the maſculine and feminine. The Greek and Latin have likewiſe the neuter, common, and the doubtful gender; and beſide theſe, they have the epicene, or promiſcuous, which under one ſingle gender and termination includes both the kinds.

The Engliſh language with ſingular propriety, following nature alone, applies the diſtinction of maſculine and feminine only to the names of animals; all the reſt are neuter; except when by a poetical or rhetorical fiction, things inanimate and qualities are exhibited as perſons, and conſequently become either male or female. And this gives the Engliſh an advantage above moſt other languages in the poetical and rhetorical ſtyle; for when nouns naturally neuter are converted into maſculine or feminine, the perſonification is more diſtinctly and forcibly marked. Lowth's Grammar, p. 44. ed. 1772.

Gender, in geometry. *Geometrical Lines* are diſtinguiſhed into *genders*, or *genera*, claſſes, or orders, according to the number of the dimenſions of the equation that expreſſes the relation between their ordinates, and the abſciſſes. See Syſtem of GEOMETRY.

GENEALOGY, a ſeries or ſucceſſion of anceſtors, or progenitors; or, a ſummary account of the relations and kindred of a perſon or family, both in the direct and collateral lines. The word is Greek, *γενεαλογια*, which is formed of *γενος*, *genus*, *proſapia*, *race*, and *lineage*; and λογος, *ſermo*, *diſcourſe*.

GENERAL, ſomething that comprehends all, or extends to a whole genus, or kind. All the ſciences have ſome *general* principles, or *axioms*. A *general* court; *general* councils are particularly called *oecumenical*.

General *Officers*, in an army, are thoſe who do not only command over a ſingle company, or regiment, but whoſe office and authority extend over a body of ſeveral regiments of horſe and foot. Such are *Brigadier-generals*, *Lieutenant-generals*, *Major-generals*, *generals* of the horſe, of the foot. See *General*, below. See alſo *Paymaſter-general*, *Commiſſary-general*, *Muſter-maſter-general*, &c. and *Pay*. We have alſo officers in law, in the revenues, &c. diſtinguiſhed by the appellation of *general*: as, *Attorney-general*, *Solicitor-general*, &c. *Receiver-general*, *Comptroller-general*, &c.

General *Terms*, among logicians, thoſe which are made the ſigns of general ideas. See ABSTRACTION, and IDEA. All things that exiſt, Mr. Locke obſerves, being particulars, it might be expected that words ſhould be ſo too in their ſignification: but we find it quite contrary; for moſt of the words that make all languages are generally terms. This is the effect of reaſon and neceſſity. For, firſt, it is impoſſible that every particular thing ſhould have a diſtinct name; becauſe it is impoſſible to have diſtinct ideas of every particular thing; to retain its name, with its peculiar appropriation to that idea.

Secondly, it would be uſeleſs, unleſs all could be ſuppoſed to have the ſame ideas in their minds. For names, applied to particular things, whereof I alone have the ideas in their minds. For names, applied to particular things, whereof I alone have the ideas in my hand, could not be ſignificant or intelligible to another who is not acquainted with all thoſe particular things which have fallen under my notice. Thirdly, it would be of no great uſe for the improvement of knowledge; which, though founded in particular things, enlarges itſelf by general views; to which things, reduced into ſorts under general names, are properly ſubſervient. In things where we have occaſion to conſider and diſcourſe of individuals and particulars, we uſe proper names: as in perſons, countries, cities, rivers, mountains, &c. Thus we ſee, that jockeys have particular names for their horſes, becauſe they often have occaſion to maintain this or that particular horſe when he is out of ſight.

Afterwards obſerving that a great number of things reſemble each other in ſhape, and other qualities, we frame a general idea that takes in only the qualities in which thoſe many particulars agree; and to this idea we give the name *man*, for example; in which there is nothing new; that which is peculiar to each individual being left out, and only that which is common to all retained. And thus we come to have a general idea and a general name. By the ſame method the mind proceeds to more general notions and names; as thoſe of animal, ſubſtance, being, thing, and ſuch univerſal terms as ſtand for any ideas whatſoever. As to the ſignification of general words, it is evident they do not barely ſignify one particular thing; neither do they ſignify a plurality; but they ſignify a genus, kind, or ſort of things. See the articles ABSTRACTION and GENUS.

General *of an Army*, is the chief commanding officer; whoſe buſineſs is to regulate the march and encampment of the army; to chooſe the moſt advantageous ground in the day of battle, to diſpoſe the army, to poſt the artillery, and to ſend his orders, wherever there is occaſion, by his aids-de-camp. At a ſiege, he is to cauſe the place to be inveſted, to regulate the approaches and attacks, to viſit the works, and to ſend out detachments for ſecuring the convoy, and for foraging. See GENERALISSMO.

The natural qualities of a *general* ſhould be a martial genius, a ſolid judgment, a healthy robuſt conſtitution, intrepidity and ſelf-poſſeſſion on critical occaſions, goodneſs of heart, liberality, and birth: he ſhould alſo be of a mean age, neither too young, becauſe he would want prudence and experience, nor too old, becauſe he would want vivacity and activity. He ſhould be ſteady and uniform in his conduct, affable in his diſpoſition, and yet inflexible in maintaining the diſcipline of his army. His acquired qualities ſhould be ſecreſy, juſtice, ſobriety, temperance, knowledge of the art of war both from theory and practice, the art of commanding and of ſpeaking with preciſion; great attention in preſerving the lives and ſupplying the wants of the ſoldiers, and a conſtant ſtudy of the characters of the officers of his army, ſo that he may be capable of employing them according to their reſpective talents. His conduct appears in eſtabliſhing his magazines in the moſt convenient places; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off; in procuring ſubſiſtence for them; and in ſelecting the moſt advantageous poſts for fighting, retreating, or ſhunning a battle. His experience inſpires his army with confidence; his quality by creating reſpect, augments his authority; his liberality enables him to procure intelligence of the ſtrength and deſigns of the enemy, and thus to take the moſt ſucceſsful meaſures. In a word, a *general* ought to be fond of glory, to have an averſion to flattery, to render himſelf beloved, and to keep a ſtrict diſcipline and ſubordination.

General *of the Artillery*. See ORDNANCE. *General of Horſe*, is an officer next under the chief *general*, who has an abſolute command of the horſe of an army, above the *lieutenant-generals*. *General of Foot*, is an officer under the chief *general*, who has an abſolute command of the foot of the army. *Adjutant General*, is an officer who attends the *general*, aſſiſts in council, and carries the *general*'s orders to the army. He diſtributes the daily orders to the majors of brigade. He is likewiſe charged with the general detail of the duty of the army. The majors of brigade ſend every morning to the adjutant-*general* an exact return, by battalion and company, of the men of their brigade. In a day of battle, the adjutant *general* ſees the infantry drawn up, after which he places himſelf by the *general*, to receive any orders which may regard the corps of which he has the detail. In a ſiege, he orders the number of workmen required, and ſigns the warrants of their payment. He receives the guards of the trenches at their rendezvous, and examines their condition; he gives and ſigns all orders for parties; he has an orderly ſerjeant from each brigade of infantry in the line, to carry ſuch orders as he may have occaſion to ſend from the *general*.

General is alſo uſed, in the military art, for a particular march, or beat of drum; being the firſt which gives notice, commonly in the morning early, for the infantry to be in readineſs to march.

GENERALISSIMO, called alſo *Captain General*, and ſimply *General*, is an officer, who commands all the military powers of a nation; who gives orders to all the other general officers; and receives no orders himſelf but from the king. Monſ. Balzac obſerves that the cardinal de Richelieu firſt coined this word, of his own abſolute authority, upon his going to command the French army in Italy.

GENERATE, in muſic, is uſed to ſignify the operation of that mechanical power in nature, which every ſound has in producing one or more different ſounds. Thus any given ſound, however ſimple, produces along with itſelf, its octave, and two other ſounds extremely ſharp, viz. its twelfth above, that is to ſay, the octave of its fifth; and the other the ſeventeenth above, or, in other words, the double octave of its third major. Whether we ſuppoſe this procreation of ſounds to reſult from an aptitude in the texture and magnitude of certain particles in the air, for conveying to our ears vibrations that bear thoſe proportions one to another, as being determined at once by the partial and total oſcillations of any muſical ſtring; or from whatever œconomy of nature we chooſe to trace it; the power of one ſound thus to produce another, when in action, is ſaid to *generate*. The ſame word is applied by Signior Tartini and his followers, to any two ſounds which, ſimultaneouſly heard, produce a third.

GENERATION, in phyſics, denotes the act of procreating, or producing a thing which before was not: or, the total change or converſion of a body into a new one, which retains no ſenſible part, or mark of its former ſtate. Thus, fire is ſaid to be *generated*, when we perceive it to be where before was only wood, or other fuel; or when the wood is ſo changed as to retain no ſenſible character of wood; thus, alſo, a chick is ſaid to be *generated*, when we perceive the chick, where before was only an egg; or when the egg is changed into the form of a chick. In *generation*, there is not properly any production of new parts, but only a new modification or manner of exiſtence of the old ones; by this, *generation* is diſtinguiſhed from *creation*. The Peripatetics explain *generation* by a change or paſſage from a privation, or want of a ſubſtantial form, to the having of ſuch a form. The moderns allow of no other change in *generation*, than what is local: according to them, it is only a tranſpoſition, or new arrangement of parts; and thus the ſame matter ſhall ſucceſſively undergo an infinity of *generations*.

A grain of wheat, e. gr. is committed to the ground: this, imbibing the humidity of the ſoil becomes turgid, and dilates to ſuch a degree, that it becomes a plant; and, by a continual acceſſion of matter, ripens by degrees into an ear; and at length into new ſeed. This ſeed ground in the mill appears in form of flour; which mixed up with water, makes a paſte; whereof with the addition, of yeaſt, fire, &c. bread is *generated*; and this bread broken with the teeth, digeſted in the ſtomach, and conveyed through the canals of the body, becomes fleſh. Now, in all this ſeries of *generations*, the only thing effected is a local motion of the parts of the matter, and their ſettling again in a different order; ſo that, in reality, wherever there is a new arrangement or compoſition of elements, there is a new *generation*; and therefore *generation* is finally reducible to motion.

GENERATION is more immediately underſtood of the production of animal and vegetable bodies from ſeed, or the coition of others of different ſexes, but of the ſame genus, or kind. Some modern naturaliſts maintain, after Monſ. Perrault, that there is not properly any new *generation*; that God created all things at firſt; and that what we call *generations*, are only augmentations and expanſions of the minute parts of the bodies of ſeeds; ſo that the whole ſpecies, to be afterwards produced, were really all formed in the firſt, and encloſed therein; to be brought forth and diſcloſed to view in a certain time, and according to a certain order and œconomy. The manner wherein the ſeed of the male animal acts on that of the female, in order to impregnate, and render it prolific, has long been enquired after, and remains ſtill a myſtery. The ancients diſtinguiſhed two kinds of *generation: regular*, called *univocal*; and *anomalous*, called alſo *equivocal*, or *ſpontaneous*. The firſt is that effected by parent animals of the ſame kind; as that of men, birds, beaſts, &c. The ſecond was ſuppoſed effected by corruption, the ſun, &c. as that of inſects, frogs, &c. But this latter kind is now generally and deſervedly exploded.

There are two principal theories, or methods of accounting for the *generation* of animals: the one ſuppoſes the embryo, or fœtus, to be originally in the ſeed of the male; the other, in the ovum, or egg of the female. The *firſt* ſuppoſes the animalcules found in the male ſeed, to be the firſt rudiments of the fœtus; and that the female only furniſhes a proper nidus, and nutriment, to bring them forwards. The *ſecond* ſuppoſes the firſt rudiments of the animal to be in the ova; and that the male ſeed only ſerves to warm, cheriſh, and ripen the ova, till they fall out of the ovary into the womb. Dr. Harvey was of opinion, that all females are furniſhed with eggs; and that *generation* is effected wholly by means of the womb; which conceives the fœtus by a kind of contagion communicated to it by the ſeminal fluid of the male, much in the ſame manner as the loadſtone communicates magnetiſm to iron. This contagion, he ſuppoſes, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; though the uterus, he acknowledges, is the only part that is capable of conceiving the fœtus, juſt as the brain is alone capable of forming ideas and notions. This ingenious phyſician and naturaliſt maintains, that the prolific fluid of the mail, neither does nor can enter into the womb of the female; but Verheyen has ſince actually found great quantity of the male ſeed in the matrix of a cow, diſſected ſixteen hours after copulation: and the celebrated Ruyſch, having diſſected a woman who was ſurpriſed in adultery and aſſaſſinated on the ſpot, found a great quantity of the ſeminal liquor of the male, not only in the cavity of the womb, but alſo in the *tubæ uteri*. Other miſtakes into which Dr. Harvey has fallen through the imperfection of the microſcope in his time, notwithſtanding his accuracy and diligence in obſerving, have been ſince detected by Malpighi, Leewenhoeck, and others. The *firſt* ſyſtem is well illuſtrated by Dr. Geo. Garden. That author, upon comparing the obſervations and diſcoveries of Harvey, Malpighi, De Graaf, and Leewenhoeck together, concludes it moſt probable, "That all animals are ex animalculo: that theſe animalcules are originally in ſemine marium, and not in that of the female; but that they can never come forward, nor be formed into animals, without the ova in the female."

The *firſt* of theſe points he argues from the three following obſervations. 1. That ſomething has often been obſerved by Malpighi, in the cicatricula of an egg before the incubation, like the rudiments of an animal, in form of a tadpole.

2. From the ſudden appearance and diſplaying of all the parts after incubation, it ſeems probable, that they are not then actually formed out of a fluid; but that the ſtamina of them have been formerly there exiſtent, and are now expanded. The firſt part of the chick, which is diſcovered with the naked eye, is the punctum ſaliens, and that not till three days and nights of incubation are paſt; on the fifth day the rudiments of the head and body appear. This made Dr. Harvey conclude, that the blood had a being before any other part of the body, and that from it all the organs of the fœtus were both formed and nouriſhed: but by Malpighi's obſervations it appears, that the parts are then only ſo far extended, as to be made viſible to the naked eye; and that they were actually exiſtent before, and diſcernable by glaſſes. After a farther incubation of thirty hours, we ſee the head, the eyes, and the carina, with the vertebræ] diſtinct, and alſo the heart. After forty hours, its repulſe is viſible, and all the other parts more diſtinct, which cannot be diſcerned by the naked eye before the beginning of the fifth day: from whence it ſeems very probable, that even the ſo early diſcovery of thoſe parts of the fœtus by the microſcope, is not the diſcerning of parts newly formed, but only parts more dilated and extended by receiving of nutriment from the coliquamentum; ſo that they ſeem all to have been actually exiſtent before the incubation of the hen. And what Swammerdam has diſcovered in the tranſmutation of inſects, gives no ſmall light to this; ſince he makes it appear, that in thoſe large erucas which feed upon cabbage, if they be taken about the time they retire to be transformed into aurelias, and plunged often in warm water, to make a rupture of the outer ſkin; you will diſcern, through the tranſparency of their ſecond membrane, all the parts of the butterfly, the trunk, wings, feelers, &c. folded up: but that, after the eruca is changed into an aurelia, none of thoſe parts can be diſcerned; but ſo much drenched with moiſture, though they be there actually formed. 3. From the analogy between plants and animals. All vegetables, we ſee, do proceed ex plantula; the ſeeds of vegetables being no other but little plants of the ſame kind, folded up in coats and membranes: whence we may infer, that ſo curiouſly an organized creature as an animal is not the ſudden product of a fluid, or coliquamentum, but does much rather proceed from an animalcule of the ſame kind, and has all its little members folded up according to their ſeveral joints and plicatures, which are afterwards enlarged and diſtended, as we ſee in plants.

The ſecond point, which our late diſcoveries have made probable, is that theſe animalcules are originally in the ſeed of the male and not in the female. For, 1. There are obſerved innumerable animalcula in ſemine maſculino, of all animals. Hartſoeker and Leewenhoeck have made this ſo evident, that there ſeems no room to doubt of it. 2. We obſerve the rudiments of a fœtus in eggs which have been fecundated by the male; though no ſuch thing is viſible in thoſe not yet fecundated. Malpighi, in his obſervations, makes it very probable, that theſe rudiments proceed originally from the male, and not from the female. 3. The reſemblance between the rudiments of the fœtus in ova, both before and after incubation, with the animalcule, makes it very probable that they are one and the ſame. The ſame ſhape and figure, which Mr. Leewenhoeck gives us of the animalcule, Malpighi gives of the rudiments of the fœtus, both before and after incubation; and even the fœtuſes of vivaparous animals appear ſo at firſt to the naked eye; whence Dr. Harvey acknowledges, that all animals, even the moſt perfect, are formed of a worm. 4. This gives a rational account of many fœtuſes at one birth; and how, at leaſt, a whole cluſter of eggs in a hen are fecundated by one coition of the male. 5. This gives a new light, as it were, to the firſt prophecy concerning the Meſſiah, that, "the ſeed of the woman ſhall bruiſe the head of the ſerpent," all the reſt of mankind being thus moſt properly and truly the ſeed of the man.

6. The analogy already mentioned, which we may rationally ſuppoſe between the manner of propagation of plants and animals, likewiſe makes this probable. Every herb and tree bears its ſeed after its proper kind; which ſeed is nothing elſe but a little plant of that kind; which being thrown into the earth, as into its uterus, ſpreads forth its roots and receives thence its nouriſhment, but has its form within itſelf; and we may rationally conjecture ſome ſuch analogy in the propagation of animals. The third thing which our diſcoveries make probable is, that animals cannot be formed of theſe animalcula without the ova in feminis, which are neceſſary for ſupplying them with proper nutriment; and this is evinced from the following conſiderations.

1. It appears that an animalcule cannot come forward, if it does not fall into a proper nidus: this we ſee in the cicatriculæ in eggs: and though a million of them ſhould fall into one egg, none of them would come forward, but what were in the centre of the cicatricula; and perhaps the nidus, neceſſary for their formation, is ſo proportioned to their bulk, that it can hardly contain more than one animalcule; which may be the reaſon why there are ſo few monſters. This, we ſee, is abſolutely neceſſary in the oviparous kinds; and the only difference that lies between them and the viviparous, ſeems to be this, that in the latter the ova are properly nothing but the cicatricula, with its colliquamentum, ſo that the fœtus muſt ſpread forth its roots in the uterus, to receive its nouriſhment; but the egg in oviparous animals may be properly termed an uterus, in relation to the fœtus; as it contains not only the cicatricula, with its amnion and colliquamentum; which is the immediate nouriſhment of the fœtus, but alſo the materials which are to be converted into that colliquamentum; ſo that the fœtus ſpreads forth its roots no farther than in the white and yolk of the egg, from whence it derives all its nouriſhment. Now, that an animalcule cannot come forward without ſome ſuch proper nidus, will not be denied; for if there were nothing needful but their being thrown into the uterus, we do not ſee why many hundreds of them ſhould not come forward at once; at leaſt while ſcattered in ſo large a field.

2. That this cicatricula is not originally in utero, ſeems evident

dent from the frequent conceptions which have been found extra uterum: ſuch as the child which continued twenty-ſix years in the woman of Thouloufe's belly; and the little fœtus found in the abdomen of Mad. de St. Mere, together with the teſticle torn and full of clotted blood; ſuch alſo ſeem to be the fœtus in the abdomen of the woman of Copenhagen, mentioned in the Nouv. de la Rep. des Lett. for Sept. 1685. all the members of which were eaſily to be felt through the ſkin of the belly, and which ſhe had carried in her belly for four years; the ſeven years gravidation related by Dr. Cole; and many other the like inſtances. Now, granting once the neceſſity of a proper nidus for the formation of an animalcule into an animal, theſe obſervations make it probable, that the teſtes are the ovaria appropriated for this uſe; for though the animalcules coming thither in ſuch caſes, may ſeem to be extraordinary, and that uſually the impregnation is in utero; yet it may be collected from hence, that the cicatriculæ or ova to be impregnated are in the teſtibus femineis; for if they were not ſo, the accidental coming of animalcules thither could not make them come forward more than in any other part of the body; ſince they cannot be formed and nouriſhed without a proper nidus.

3. It is acknowledged, that the fœtus in utero, for ſome conſiderable time after conception, has no connexion with the womb; that it ſits wholly looſe in it, and is no other than a little round egg, with the fœtus in the midſt; which ſends forth its umbilical veſſels by degrees, and at laſt lays hold of the uterus. Now from hence it ſeems evident, that the cicatricula, which is the fountain of the animalcule's nouriſhment, does not ſpout from the uterus, but has its origin elſewhere; and falls in thither as into a fit ſoil, from whence it may draw nutriment for the growth of the fœtus: elſe it cannot be eaſily imagined how it ſhould not have an immediate connection with the uterus, from the time of conception. It is indeed difficult to conceive, how theſe eggs ſhould be impregnated per ſemen maris, both becauſe there is no connexion between the Fallopian tubes, and the ovary for its tranſmiſſion; and becauſe Dr. Harvey could never diſcover any thing of it in utero: but as to the laſt, Mr. Leewenhoeck has cleared that difficulty by the diſcovery of innumerable animals in the tubæ, or cornua uteri, and thoſe living a conſiderable time after coition. And as to the former, we may either ſuppoſe, that there is ſuch an inflation of the tubæ, at the time of coition, as makes them embrace the ovaries; and ſuch an approach of the uterus and its cornua, as that it may eaſily tranſmit the ſeed into the ovary: or elſe, that the ova are impregnated by the animalcules after they deſcend into the uterus, and not in the ovary. The former ſeems probable for this reaſon, that at leaſt a whole cluſter of eggs in a hen will be fecundated by one tread of the cock: now this fecundation ſeems to be in the vitellary and not in the uterus, as the eggs paſs along from day to day: for it can hardly be ſuppoſed, that the animalcules ſhould ſubſiſt ſo long, being ſcattered looſely in the uterus, as to wait there for many days, for the fecundation of the eggs as they paſs along. The latter conjecture has this to ſtrengthen it; that the animalcules are found to live a conſiderable time in the uterus; and that if they ſhould impregnate the ova in the ovary itſelf, the fœtus would increaſe ſo faſt, that the ova could not paſs through the tubæ uteri; but would either burſt the ovary, or fall down into the abdomen, from the orifices of the tuba; and from hence probably proceed thoſe extraordinary conceptions in the abdomen, out of the uterus. Thus much is urged for the ſyſtem *ab animalculo*. See Foetus.

The retainers to the ſyſtem of *generation ab ovo* contend, that the rudiments of the fœtus are laid in the ovary, and that the female furniſhes the whole matter of the body; which they chiefly ſupport from the conformation in rabbets, ſheep, cows, &c. where the vagina of the womb is ſo long, and ſinuous, that it is ſcarce poſſible the male ſeed ſhould ever arrive within the body of the uterus; eſpecially in cows, whoſe vagina are filled with a thick, viſcid ichor, and the inner orifice of the womb is exactly cloſed; beſides that the thickneſs of the membranes of the ova ſhould ſeem impenetrable to ſo craſs a matter as the male ſeed. And, that if animalcula be found in the male ſeed, which, however, will admit of ſome diſpute (that inteſtine motion and agitation of the groſſer particles thereof, which gave riſe to the opinion, being accountable for, from the common laws of warm fluids); yet are the ſame obſerved in vinegar, pepper-water, &c. Add, that it is highly improbable, that thoſe animalcules ſhould contain the rudiments of a future body; ſince their large numbers would produce too plentiful an offspring; inſomuch that it would be neceſſary for 9999 parts of them to be in vain, and periſh: which is contrary to the œconomy of nature in other things. Analogy is likewiſe urged in favour of this ſyſtem: thus all plants are maintained to ariſe from eggs; ſeeds being no other than eggs under another denomination. All oviparous animals do unexceptionally ariſe from eggs, which the females caſt forth; and it is highly probable, that the viviparous only differ from the oviparous, in that the females lay and hatch their eggs within themſelves. Againſt this hypotheſis it is urged, that what are uſually called *ova* or *eggs*, in women, are no other than little cells, or bladders, full of a certain liquor; and how can a drop of liquor paſs for an egg? Add, that theſe imaginary eggs have no proper membrane belonging to them, nor any covering but that of the cell; which ſeems ſo inſeparable therefrom, that, when they are diſcharged, it is hard to conceive how they ſhould take it with them. And beſide, how ſhould they make themſelves a paſſage through the common membrane wherewith the ovary is inveſted which is of ſo cloſe a texture that it muſt ſeem abſolutely impenetrable by a round body of ſo ſoft a conſiſtence as one of theſe veſicles? Laſtly, veſiculæ, in all reſpects perfectly like ova, have been found in other parts of the body, where it is apparent they could not ſerve for any purpoſes of *generation*. Mem. de l'Acad. Royal. de Scien. an. 1708, 1709.

To this it is anſwered, that ova or veſiculæ have been actually found in diſſections, detached and ſeparated from the ovary, and the ruptures in the membrane of the ovary, through which they had paſſed, remaining ſtill viſible. M. Littre even obſerved ſome of theſe ſeparated ova ſpread with blood-veſſels, like thoſe in the yolks of birds eggs. Nay, more; the ſame author is poſitive, that he ſaw an embryo in one of the ova not yet ſeparated; and could diſcern its head, mouth, noſe, trunk and funiculis umbilicalis, whereby it adhered to the membranes of the ovary. See Generation *of Man*.

Sir John Floyer ſtarts a difficulty, which ſeems to preſs equally againſt each ſyſtem, taken ſingly: it is fetched from monſters. In a mule for inſtance, which is the production of a venereal copula between an aſs and a mare, the bulk of the body partakes of the form of the dam, and the feet, tail, and ears, of that of the ſire. Hence it is argued, that the rudiments of the greater part of the fœtus are laid in the ovum; and that the impregnation either conveys or changes the extremities. If the male ſupplied the animalcula, the fœtus ſhould always be of the ſame ſpecies as the male: if the female ſupply it, it ſhould be of her kind; whereas monſters are of both. Three other ſyſtems of *generation*, which indeed ſo much reſemble one another, that they may be reduced to one, have been lately formed from the experiments and obſervations of Monſ. de Buffon, Monſ. de Maupertuis, and Mr. Needham.

Monſ. de Buffon has endeavoured to prove that the ova in women and quadrupeds are chimeras, and that the ſpermatic animalcule cannot be the *fœtus*. He could never find any ova which had detached themſelves from the ovary, and paſſed through the Fallopian tube into the matrix. But he diſcovered a glandular body on the female teſticle, which anatomiſts had miſtaken for one of theſe; which glandular body, at certain times, ſwelled, opened and diſcharged a liquor full of the ſame animalcules, which Leewenhoeck, took for living creatures in the ſemen of males. And Monſ. de Buffon adds, that he found bodies perfectly ſimilar to theſe, not only in the ſemina of very different animals, but in the infuſions of plants, of grains, and in the juices of fiſh-meats, dreſſed and prepared by the fire ſo as to leave no creature living in them. From whence this ingenious gentleman concludes, that theſe pretended animalcules are not future animals of the ſpecies of the father; he does not even allow them to be true animals, but ſays they are ſomething of an intermediate nature between brute matter and animals; parts organized and animated, the aſſemblage of which forms the fœtus, ſee Lettres de Monſ. de Maupertuis, let. 17.

But the chief difficulty conſiſts in conceiving how the fœtus is formed from theſe elements. Monſ. de Buffon thinks that every part, both of animals and vegetables, contains an infinite number of organic molecules; but that they are much more numerous in the ſeminal liquors of both ſexes, and in the ſeeds of plants, than in other parts. Theſe organic parts ſerve for the nutrition and growth of animals and plants; and the ſurplus of theſe parts, when the other purpoſes to which they are adapted and anſwered, being reunited in proper interior moulds, correſponding to the ſize and ſhape of the animal or vegetable to be produced, forms ſuch animals or vegetables. And thus the unity and diverſity of the ſeveral ſpecies are preſerved and continued. When the quantity of this organic matter is ſmall, as in man and moſt large animals, *generation* only takes place at a certain age of maturity, and even then the number of animals is but ſmall. In other animals, as in fiſhes, and moſt birds, abounding with theſe organic parts the caſe is juſt the reverſe. With regard to the *generation* of mankind, he ſuppoſes that the ſuperfluous organic parts are collected together into the ſeminal veſſels of the male and the teſticles of the female, which are the reſervoirs deſtined to receive them: and in theſe reſervoirs, they form a prolific liquor in each ſex, which has been previouſly extracted from every part of the body. Theſe ſeminal liquors, compoſed of parts alike active and perfectly analogous to one another, in form and motion, are mixed in the womb, and contribute, by uniting with each other, to the formation of the fœtus, which is either male or female, as the ſeed of the man or woman abounds moſt with organic molecules; and the infant reſembles either the father or mother, according to their different combinations of theſe molecules. The organic parts of theſe liquors, being equally active, fix and counterbalance each other; ſo that the molecules of each parent are determined to form ſimilar parts to thoſe of the individual that furniſhed them, as the head, arms, &c. The molecules proceeding from the genital part fix themſelves firſt: and the other molecules arrange themſelves ſucceſſively round theſe in the ſame order which they before occupied in the parent. When a great quantity of the ſeminal liquors of both ſexes is received into the womb, there are formed different ſpheres of attraction, in different parts of theſe liquors; the conſequence of which is that ſeveral fœtuſes are formed at the ſame time. For a fuller account of Monſ. de Buffon's ſyſtem, we muſt refer to his Hiſtoire Naturelle, printed at Paris, 1752, where the ſubject of the *generation* of animals takes up the greateſt part of the third volume.

Monſ. de Maupertuis's ſyſtem in his Venus Phyſique, has a near reſemblance to that of Monſ. de Buffon, and tends equally to overturn the firſt ſyſtem of *generation*, called os animalculo, eſpouſed by Dr. George Gulen, the ſecond Syſtem of *generation*, called *ab avo*, which have prevailed among modern phyſiologiſts. He aſcribes the formation of the fœtus to the mixture of the male and female ſeed, by means of the affinity and mutual attraction of the correſponding parts that compoſe them. And to confirm his own and Monſ. de Buffon's opinion, he adds an accouut of a ſexdigitary family, as he calls it, at Berlin, many of which had a ſupernumerary finger or toe, and ſometimes both. He ſays that this ſexdigitiſm, or quality of having ſupernumerary fingers or toes, has been tranſmitted equally by the father and by the mother; that it was loſt by alliances with thoſe who had but the common number of fingers. He adds, that he does not believe that any one will aſcribe the continuation of ſexdigitiſm in a family, to chance; theſe ſupernumerary parts might have been accidental varieties at firſt, but if they be once eſtabliſhed by a ſufficient number of *generations*, where both ſexes have had them, they then become a foundation for a diſtinct ſpecies; and perhaps all the different ſpecies, diſcernable in animals of the ſame kind, have been multiplied in this way. What we may obſerve in other animals gives ground for theſe ſuſpicions.

Mr. Turbervill Needham, in his Summary of Obſervations on the *Generation*, Compoſition, and Decompoſition of animal and vegetable Subſtances, having offered ſeveral objections againſt the ſyſtems of *generation* by eggs and by animalcules, recites a multitude of experiments, from which he concludes, that there are no pre-exiſtent germs formed for the production of animals and vegetables; but that matter, in ſome degree organized in its minute aſſemblages, gives birth to them, and that the gradation between animal and vegetable life is much more familiar and eaſy than it had before appeared to be. He ſuppoſes, in conformity to the doctrine of Monſ. de Buffon, that there are in matter certain organical parts, diſpoſed for the formation of animal and vegetable ſubſtances; that theſe, by coalition, conſtitute the *prima ſtamina* of all animal and vegetable bodies, which are ſimple, uniform, and common to all, and conſequently to be found in a certain quantity in every portion of food, aliment, or nutritive juice; and from thence to be digeſted, and when the ſubject becomes adult, to be ſecreted and ſtrained, for the formation of the ſeed of every plant and animal; and in this fluid or ſubſtance to be afterwards found in great abundance.

Into theſe organical principles, Mr. Needham reſolves that claſs of beings which has been denominated microſcopic animals. He tells us, that ſeeds macerated in water firſt diſunite into ſmall particles, motionleſs, and ſeemingly inert: but that theſe particles by degrees afterwards arrive at a power of motion, and ſeem alive, though in reality they are not ſo. The author deduces the ſame obſervations from experiments on the juices of animals, mutton gravy, and the like; and affirms, from the whole, that no axiom was ever more true than that of the ancients, *corruptio unius eſt generatio alterius*, that is the corruption, one is the generation of another, though they draw it from falſe principles, and ſo eſtabliſhed it as to render *generation* equivocal. He then proceeds to the examination of the male ſemen of animals; and affirms, that thoſe animalcules appearing like tadpoles, which others have obſerved in this ſemen, are produced ſubſequently to the evacuation of this fluid, and have their origin from principles contained in this matter, either by evolution of organical parts, as Buffon ſuppoſes, or, as Mr. Needham thinks, from a real vegetation, and a change from the vegetable to the animal life, he ſays that the ſemen, immediately evacuated, and viewed by the microſcope, appears an homogeneous fluid; that, after a few moments, it begins to liqueſy; then to ſhoot out into long filaments and ramifications on every ſide; which afterwards open and divide into moving globules, trailing after them ſomething like long tails; theſe tails are in reality no parts of the animals, but long ſtrings or filaments of the viſcid ſeminal ſubſtance, which gradually becomes ſhorter and ſhorter, till at laſt the globules get rid of them, and ſwim equally in the fluid. This vegetative power, in parts of the ſemen, of ſhooting into filaments, Mr. Needham found to reſide in all ſubſtances, animal and vegetable, and in every part of thoſe ſubſtances, as far as the ſmalleſt microſcopical point; and to this he attributes all that is called animal life in the fluids, produced from vegetables, or the infuſions of them; and from hence he concludes with M. Buffon, that there is a real productive force in nature. He adds, that there is a vegetative force in every microſcopical point of matter, and in every viſible filament of which the whole animal or vegetable texture conſiſts; and he alſo conjectures, that this force extends much farther; becauſe in all his obſervations, the whole ſubſtance, after a certain ſeparation of ſalts and volatile parts, divided into filaments and vegetated into numberleſs zoophytes, which yielded all the ſeveral ſpecies of common microſcopic animals; and theſe animals alſo, after a certain time ſubſided to the bottom, became motionleſs, reſolved again into a gelatinous filamentous ſubſtance, and gave zoophytes and animals of a leſſer ſpecies. The caſe is the ſame, he ſays, with regard to the ſpermatic animalcules as well as the others, and, therefore, he reduces them all to the ſame claſs of beings. From theſe facts, he infers, that every animal or vegetable ſubſtance advances as faſt as it can in its reſolution to return to one common principle, the ſource of all, or a kind of univerſal ſemen, from which its atoms may return again and aſcend to a new life.

Mr. Needham alſo obſerves, that the animalcules in the ſemen of animals, and in the infuſions and juices of animal and vegetable ſubſtances, are not of the nature of any other beings, or to be ranked with them: that they conſtitute a claſs apart from all others, the characteriſtic of which is, that they are neither generated nor ſubſiſt by nutriment, as other plants, and animals do, nor generate in the ordinary way. Of this claſs, he apprehends, is that ſpecies of POLYPE, called the bell animal (See ANIMALCULES) owing its formation to the decompoſition of ſome water plants, but approaching towards the nature of other animals, as, when once generated, it eats, and even generates as other animals do.

Mr. Needham's ſyſtem may be ſummed up in a few words: he ſuppoſes all ſemen of any kind to be an exalted portion of animal or vegetable matter, ſecreted from the aliment of every generating ſubject, when it is adult, and no farther demand is made for its increaſe of growth; this is endued with a proportionable vegetating force; and is various in various circumſtances, and heterogeneous in different ſubjects, but uniform in its productions, when it falls into a proper matrix, where it finds matter to aſſimilate of a proper quality, and in a quantity ſufficient to form that ſpecific being: whilſt in other circumſtances, it will, if it extravaſates, by the ſame vegetating force, produce the ſeveral phænomena which he has aſcribed to it. Phil. Tranſ. vol. xlv. p. 615, &c.

GENERATION *of Man*. As it is in the human ſubjects that the gradual proceſs of *generation* has been principally inquired into, and the ſtructure and office of the organs ſubſervient thereto, chiefly examined: what the lateſt naturaliſts and anatomiſts have ſettled with regard to it, is reſerved for this head. The parts of *generation*, then, are different in the different ſexes. Thoſe proper to the male, are the penis, the teſticles, the veſiculæ ſeminales, the vaſa deferentia, the paraſtatæ and the vaſa præparentia; which ſee deſcribed each under its proper article, PENIS, TESTICLE, &c. The parts of *generation* proper to the female are the PUDENDUM, the CLITORIS, NYMPHÆ, HYMEN, UTERUS, FALLOPIAN TUBES, and OVARIES OF TESTES, which we have fully deſcribed in our Syſtem of ANATOMY.

The proceſs of *generation*, ſo far as the male contributes to it, is as follows. The penis being erected by an affuſion of blood, as ſhewn under erection; the glands, at the ſame time tumefied; and the nervous papillæ in the glands much rubbed, and highly excited, in coitu: an ejaculatory contraction follows, by which the ſeed is preſſed out of the ſeminal veſicles, and expelled with ſome conſiderable force. The proceſs of *generation* on the one part of the female is thus: the clitoris being erected, after the like manner as the penis in man; and the neighbouring parts all diſtended with blood; they more adequately embrace the penis in coitu: and, by the intumeſcence, preſs out a liquor from the glands about the neck of the womb, to facilitate the paſſage of the penis. At the ſame time, the fibres of the womb, contracting, open its mouth (which at other times is extremely cloſe) for the reception of the finer part of the ſeed.

Thus the ſeed, pregnant with animalcules, is conveyed, with ſome impetus, into the uterus: where being retained by the convulſive reſtriction of the inner membrane thereof, and farther heated and agitated therein, it is prepared to impregnate the ovum.

During the act of coition, the Fallopian tubes growing ſtiff, embrace the ovaries with their ſtrong muſculous edges like fingers, and compreſs them, till their mouths being dilated and expanded by this membrane, force the egg now ripened, into their cavities, and gradually drive it forwards, by their virmicular motion, till at laſt they protrude into the cavity of the womb to meet the ſeed, ſome of the animalcules whereof, entering the dilated pores of the glandulous membrane of the egg, are there retained, nouriſhed, grow to its navel, and ſuffocate the reſt of the leſs lively animalcula. And thus is conception performed. Others rather ſuppoſe the ſeed conveyed from the uterus, through the Fallopian tubes, to the ova; and thus take the impregnation to be firſt performed in the ovaries, or even in the tubæ themſelves, the ova and the ſeed meeting by the way. Others, conſidering the cloſeneſs of the mouth of the womb, and the thickneſs of the membranes of the ovaries, judge it impoſſible for the ſeed to paſs that way; and therefore ſuppoſe it is taken up by the veins which open into the cavity of the vagina, or even the womb; where circulating, it ferments with the maſs of blood; and hence all the ſymptoms which appear in conception. At length it enters and impregnates the egg by the ſmall twigs of arteries which are upon its membranes. This fermentation ſwelling the membranes of the tubæ, they open their cavity, and make room for the ova to paſs into the womb. The egg impregnated, and cloſe ſhut up in the womb, ſwims in the humours thereof; which, growing more and more ſubtil, enter the parent pores found on one ſide the ovum, and ſoon diſtend, fill, and augment it: and there being ſtill farther attenuated, nouriſh the embryo; thicken and expand the membranes of the ovum, eſpecially in that part by which it grew to the ovary; and thus form the rudiments of a placenta. The ſame cauſes ſtill continuing, and the pores both of the placenta and the membranes being enlarged; the egg begins to fill the cavity of the womb: and at length its ſtem or calyx grows to the concave ſurface thereof: and thus is the navel ſtring, or funiculus, formed. See FOETUS and *Funiculus* UMBILICALIS.

This ſyſtem is founded on the ſuppoſition of animalcula in the male ſeed. They who ſet them aſide as unconcerned in generation, account for it thus: the ſeed containing volatile, oily, and ſaline parts, as appears from its fœtid ſmell, oleaginous ſubſtance, &c. being lodged in the womb, and there farther digeſted and exalted, grows yet more volatile, fetid, pungent, and ſtimulating; and thus, adding to the heat occaſioned by coition villicates the nervous fibres of that part, and occaſions a fermentation, and gentle inflammation; and by that means an extraordinary flux of humours to that and the adjacent parts. By this means the tubæ becomes rigid, and fit to graſp the ovaries, which are always heated by the effluvia of the ſemen and the warmth of the parts ſurrounding. Upon this there is a greater flux into the ovaries; till at length, the ova, ſome of them at leaſt, by ſuch greater ſupply of nouriſhment, increaſe in bulk; and as thoſe graſped by the edges of the tubæ will be kept warmeſt, and the greateſt flux be made thereto, they will ſooneſt be ripened, fall off, and be received by the tubæ, and conveyed to the womb; where growing after the manner of the ſeeds of plants, the placenta at length takes hold of, and adheres to, the uterus; from which time the embryo begins to be nouriſhed after a different manner. See GESTATION, NUTRITION and CIRCULATION.

Whoever reads this ſhort ſketch of the different theories of generation that have hitherto been invented, will probably require no other arguments to convince him, that phyſicians and philoſophers are ſtill ignorant of the nature of this myſterious operation they were in the days of Noah. Concerning the formation and nutrition of the fœtus after the female has conceived, there have alſo been great diſputes; but as this ſubject is more eaſily inveſtigated, and in ſome meaſure falls under the notice of our ſenſes, there is much leſs uncertainty concerning theſe matters than generation, or the manner in which the embryo is originally formed. The following particulars are confirmed by the greateſt number of obſervations.

About the ſeventh day, the eye may diſcover the firſt lineaments of the fœtus; but theſe lineaments are as yet very imperfect. Two little veſicles appear in an almoſt tranſparent jelly, the largeſt of which is deſtined to become the head of the fœtus, and the other ſmaller one is reſerved for the trunk. But at this period no extremities are to be ſeen; the umbilical chord appears only as a very minute thread, and the placenta does not as yet abſorb the red particles of the blood. At the end of fifteen days, not only the head but the features of the face begin to be developed. The noſe appears like a ſmall prominent line; and we are able to diſtinguiſh another line under it, which is deſtined for the ſeparation of the lips. Two black points appear in the place of eyes, and two minute holes mark the ears. At the ſides of the trunk both above and below, we ſee four minute protuberances, which are the rudiments of the arms and legs. At the end of three weeks the body of the fœtus is ſomewhat augmented, and both the hands and feet are to be diſtinguiſhed. The upper extremities are found to increaſe faſter than the lower ones, and the ſeparation of the fingers is accompliſhed ſooner than that of the toes. Towards the end of the firſt month, the fœtus is about an inch long, and the human form may be deciſively aſcertained: all the parts of the face may be diſtinguiſhed; the ſhape of the body is clearly marked out, the haunches and the abdomen are elevated, the fingers and toes are ſeparated from each other, and the inteſtines appear like minute threads. After ſix weeks the fœtus is grown much longer, and the human figure appears to be more perfect, but the head is ſtill larger in proportion than the other parts of the body.

At the end of the ſecond month, the fœtus meaſures two inches and a quarter; at the end of the third month, three inches and a quarter; at the end of the fourth month, three inches and a half; and about the fourth or fifth month, uſually about five inches; and from that time to the end of the ninth month, it gradually increaſes to about the length of twelve inches, ſometimes more, and ſometimes not quite ſo much. The fœtus during all this time aſſumes an oval figure, which correſponds with the ſhape of the uterus. Its chin is found reclining on its breaſt, with its knees drawn up towards its chin; and its arms folded over them. But it ſeems likely that the poſture of ſome of theſe parts is varied in the latter months of pregnancy, ſo as to cauſe thoſe painful twitches which its mother uſually feels from time to time. In natural caſes, its head is probably placed towards the os tincæ from the time of conception to that of its birth; though formerly it was conſidered as being placed towards the fundus uteri, till about the eighth or ninth month, when the head, by becoming ſpecifically heavier than the other parts of the body, was ſuppoſed to be turned downwards. The capacity of the uterus increaſes in proportion to the growth of the fœtus, but without becoming thinner in its ſubſtance, as might naturally be expected. The nouriſhment of the fœtus, during all this time, ſeems to be derived from the placenta, which appears to be originally formed by that part of the ovum which is next the fundus uteri. The remaining unconnected part of the ovum, and likewiſe the ſurface of the placenta, are covered by a membrane called *chorion*, within which is another pellucid membrane called *amnios*. Beſides theſe two membranes, Dr. Hunter has diſcovered a third, which is the exterior one, being ſuppoſed to be a lamella from the inner ſurface of the uterus. In the latter months of pregnancy it becomes gradually thinner and more connected with the chorion. He has named it *membrana caduca*. In ſome quadrupeds, the urine appears to be conveyed from the bladder through a canal called *urachus*, to the *allantois*; which is a reſervoir, reſembling a long and blind gut, ſituated between the chorion and amnios. The human fœtus ſeems to have no ſuch reſervoir, though ſome writers have ſuppoſed that it does exiſt. From the top of the bladder, a few longitudinal fibres are extended to the umbilical chord; and the fibres have been conſidered as the urachus, though without having ever been found pervious.

The two former include a watery fluid, which is the *liquor amnii*, in which the fœtus floats till the time of its birth. The *liquor amnii* coagulates like the lymph. It has been ſuppoſed to paſs into the œſophagus, and to afford nouriſhment to the fœtus; but this does not ſeem probable. Children have come into the world without an œſophagus, or any communication between the ſtomach and the mouth; but there has been no well atteſted inſtance of a child's having been born without a placenta; and it does not ſeem likely that any of the fluid can be abſorbed through the pores of the ſkin, the ſkin in the fœtus being every where covered with a great quantity of mucus. In the firſt months of pregnancy, the involucra bear a large proportion to their contents, but this proportion is afterwards reverſed as the fœtus increaſes in bulk. The placenta, which is the medium through which the blood is conveyed from the mother to the fœtus, and the manner in which this conveyance takes place, deſerve to be clearly deſcribed, as being a ſubject not generally underſtood. Without ſuch an explanation it might perhaps be readily ſuppoſed, that the arteries of the uterus paſs into the ſubſtance of the placenta; and that the blood, after being conveyed through the umbilical arteries to the fœtus, is returned back by the umbilical vein to the placenta, and from thence to the uterus. Such an idea, however, would be a very erroneous one, and we ſhall point out the true manner in which this proceſs is conducted.

The *placenta* is a broad, flat, and ſpongy ſubſtance, like a cake, cloſely adhering to the inner ſurface of the womb, uſually near the fundus, and appearing to be made up by the ramifications of the umbilical arteries and vein. The arteries of the uterus diſcharge their contents into the ſpongy cells of this cake; and the veins of the placenta, abſorbing the blood from theſe cells in the ſame manner as they abſorb it in the copora cavernoſa penis, at length forms the *umbilical vein*, which paſſes on to the liver, and from thence to the heart of the fœtus, by the vena cava. Its circulation however, through the heart is not conducted in the fœtus as it i in the adult: in the latter, the blood is carried from the right au ricle of the heart through the pulmonary artery, and is returned to the left auricle by the pulmonary vein; but a dilatation of the lungs is eſſential to the paſſage of the blood through the pulmonary artery, and this dilatation cannot take place till after the child is born and has reſpired. This deficiency, however, is ſupplied in the fœtus by an immediate communication between the right and left auricle of the heart, through an oval opening in the ſeptum, which divides the two auricles, called *foramen ovale*. The blood is returned again from the fœtus, through two arteries called the *umbilical arteries*, which ſometimes ariſe from the iliacs, and ſometimes from the aorta deſcendens. Theſe two veſſels taking a winding courſe with the vein, form with that, and the membranes by which they are ſurrounded, what is called the *umbilical chord*. Theſe arteries, after ramifying through the ſubſtance of the placenta, open and diſcharge their blood into its cells, from whence it is abſorbed by the veins of the uterus; ſo that a conſtant depoſition and abſorption are carried on, and the fœtus is found to have a circulation independent of its mother.

GENERATION *of Fiſhes*. See Syſtem of ICHTHYOLOGY.

GENERATION *of Plants*. See Syſtem of BOTANY, Sect. VI.

GENERATION *of Inſects*. See Syſtem of ENTOMOLOGY, Part I.

GENERATION *of Parts*. See Syſtem of ANATOMY; for the male organs, Part III. Sect. II. for the female, Part V. Sect. I. for a repreſentation Plate X.

GENERATION is alſo uſed, though ſomewhat improperly, for GENEALOGY, or the ſeries of children iſſued from the ſame ſtock. Thus, the goſpel of St. Matthew commences with *the book of the generation of Jeſus Chriſt*, &c. The latter, and more accurate tranſlators, inſtead of *generation* uſe the word *geneaology*.

GENERATION is alſo uſed to ſignify a people, race, or nation, eſpecially in the literal tranſlations of the ſcripture, where the word generally occurs wherever the Latin has *generatio*, and the Greek γενεα, γενεσις.

Thus, "A wicked and preverſe *generation* ſeeketh a ſign," &c. "One *generation* paſſes away, and another cometh," &c.

Generation is alſo uſed in the ſenſe of an age, or the ordinary period of a man's life. Thus we ſay, to the third and fourth *generation*. In this ſenſe, hiſtorians uſually reckon a *generation* the the ſpace of thirty-three years, or thereabouts. See Age.

GENERICAL *Name*, in natural hiſtory, the word uſed to ſignify all the ſpecies of natural bodies, which agree in certain eſſential and peculiar characters, and therefore all of the ſame family or kind; ſo that the word uſed as the *generical* name equally expreſſes every one of them, and ſome other words expreſſive of the peculiar qualities or figures of each are added, in order to denote them ſingly, and make up what is called a ſpecific name. Thus the word *roſe*, or roſe, is the *generical* name of the whole ſeries of flowers of that kind, which are diſtinguiſhed by the ſpecific names of the red roſe, the white roſe, the apple roſe, &c. The ignorance of former ages, in the true principles of natural hiſtory, has occaſioned the bodies, which are the objects of it, to be arranged into very unnatural ſeries under the name of *genera*; and theſe have been called by names as improper as the characters they were diſtinguiſhed by. Linnæus has done a great deal in exploding the bad *generical* names in Botany.

GENESIS, the firſt book of the Old Teſtament, containing the hiſtory of the creation, and the lives of the firſt patriarchs. The book of *Geneſis* ſtands at the head of the Pentateuch. Its author is held to be Moſes: it contains the relation of 2369 years, viz. from the beginning of the world to the death of Joſeph. This book, beſides the hiſtory of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the riſe of religion; the general defection and corruption of the world; the deluge; the reſtoration of the world; the diviſion and peopling of the earth; and the hiſtory of the firſt patriarchs to the death of Joſeph. It was eaſy for Moſes to be ſatisfied of the truth of what he delivers in this book, becauſe it came down to him through a few hands: for from Adam to Noah, there was one man, viz. Methuſelah, who lived ſo long as to ſee them both: in like manner Shem converſed with Noah and Abraham; Iſaac with Abraham and Joſeph, from whom the records of this book might eaſily be conveyed to Moſes by Amram, who was contemporary with Joſeph.

GENEVA, or Gin, a popular name for a compound water, which is, or ought to be, procured from the berries of the juniper-tree, diſtilled with brandy or malt-ſpirits. The word is formed from *genevre*, the French name of the Juniper-berry. The beſt *geneva* we now have, is made from an ordinary ſpirit, diſtilled a ſecond time with an addition of ſome juniper berries; but the original liquor of this kind was prepared in a very different manner. It was a cuſtom in the diſtilling of ſpirits from wort, or other fermented liquors, to add in the working ſome aromatic ingredient, ſuch as ginger, cortex Winteranus, or grains of paradiſe, to take off the bad flavour, and to give a pungent taſte to the ſpirit. Among other things uſed with this intent, ſome tried the juniper berries, and finding that they gave not only an agreeable flavour, but very valuable virtues alſo to the ſpirit, they brought it to a general cuſtom, and the liquor ſold under this name. The method of adding the berries was to the malt in the grinding: a proper proportion was allowed, and the whole was reduced to meal together, and worked in the common way. The ſpirit thus obtained was flavoured *ab origine*, with the berries, and exceeded all that could be made by any other method. Our common diſtillers leave out the juniper berries entirely from the liquor they now make and ſell under that name. Our chymiſts have let them into the ſecret, that the oil of juniper berries, and that of turpentine, are very much alike in flavour, though not in price: and the common method of making what is called *geneva* in London, is with common malt ſpirit, and a proper quantity of oil of turpentine diſtilled together. Shaw's Eſſay on diſtill. p. 7.

GENIAL, Genialis, an epithet applied by the ancients to certain deities, whom they ſuppoſed to preſide over generation.

GENICULI, in botany, the joints or knots which appear in the ſhoots of plants; whence botaniſts call thoſe marked therewith *geniculate plants*.

GENIO-HYOIDÆUS, in anatomy, a muſcle of the *os hyoides*. For the origin, inſertion, and uſe of theſe muſcles, ſee the Syſtem of Anatomy, Sect. XI.

GENITAL, Genitalis, in anatomy, ſomething that relates to generation. Genital parts denote the parts, in both ſexes, employed in generation. See Generation.

GENETIVE, in grammar, the ſecond caſe of the declenſion of nouns. The relation of one thing conſidered as belonging in ſome manner to another, has occaſioned a peculiar termination of nouns, called the *genetive caſe*; but, in the vulgar tongues, they make uſe of a ſign to expreſs the relation of this caſe. In Engliſh they prefix the particle *of*, in French *de* or *du*, &c.: Though in ſtrictneſs there are no caſes in either of theſe languages; inaſmuch as they do not expreſs the different relations of things by different terminations, but by additional prepoſitions, which is otherwiſe in the Latin.

GENIUS, in mythology, a good or evil ſpirit, or demon, whom the ancients ſuppoſed to ſet over each perſon, to direct his birth, accompany him in life, and be his guard until death.

Genius is more frequently uſed for the force or faculty of the ſoul conſidered as it thinks or judges. Thus, we ſay, a happy *genius*, a ſuperior *genius*, an elevated *genius*, a narrow confined *genius*, &c. In like ſenſe we alſo ſay, a work of *genius*, a want of *genius*, &c.

Genius is alſo uſed in a more reſtrained ſenſe, for a natural talent, or diſpoſition to one thing more than another. In which ſenſe we ſay a *genius* for verſe, for the ſciences, &c. Art and induſtry add much to natural endowments, but cannot ſupply them where they are wanting. Every thing depends on genius. A painter often pleaſes without obſerving rules; whilſt another diſpleaſes though he obſerves them, becauſe he has not the happineſs of being born with a genius for painting. Nature has thought fit to make a diſtribution of her talents among men, in order to render them neceſſary to one another; the wants of men being the very firſt link of ſociety: ſhe has therefore pitched upon particular perſons, to give them aptitude to perform rightly ſome things which ſhe has rendered impoſſible to others; and the latter have a greater facility granted them for other things, which facility has been refuſed to the former. Nature, indeed, has made an unequal diſtribution of her bleſſings among her children; yet ſhe has diſinherited none; and a man diveſted of all kinds of abilities, is as great a phenomenon as an univerſal genius.

GENTILE, Gentilis, a pagan, or perſon who adores falſe gods. The Hebrews applied the name גוים, *gentes*, *nations*, to all the people of the earth who were not Iſraelites or Hebrews. Some will have it that the *gentiles* were thus called in contradiſtinction to the Jews, becauſe the latter had a poſitive law to obſerve in matters of religion, whereas the *gentiles* had only the natural law; hence they are called *gentiles*.

GENTLEMAN, a perſon of good family, or deſcended of a family which has long borne arms, the grant of which adds gentility to a man's family. In our ſtatutes, *gentilis homo* was adjudged a good addition for a *gentleman*, 27 Edw. III. The addition of knight is very ancient: but that of eſquire, or *gentleman*, was rare before 1 Hen. V. We read that J. Kingſton was made a *gentleman* by king Richard II. As it may juſtly be aſked, what conſtitutes a *gentleman* with us? the reply is eaſy; being a *gentleman*, is being entitled to bear arms. And Mr. Camden obſerves, that the diſtinction of a *gentleman* of coat armour, or an upſtart, and a *gentleman* of blood, is the bearing of arms from the grandfather; and that he who bears arms from his grandfather, is to all intents and purpoſes a *gentleman* of blood; for which cauſe it is requiſite by the ſtatutes of the Bath that every knight before his admiſſion, proves himſelf to be ſo qualified; which done it carries with it, if his merit be equal, a paſſport alſo to the order of the Garter. Notitia Anglicana, p. 24. See alſo Doddridge's Honour's Pedigree, p. 147. Smith, De Republ. Ang. & Forteſcue, fol. 82.

Guillim, in his chapter of *gentlemen*, ſays, that they have their beginning either of blood, as being born of worſhipful parents; or that they have done ſomething, either in peace or war, whereby they deſerve to bear arms, and be accounted *gentlemen*. He farther ſays, chap. xxiv. if a *gentleman* be bound apprentice to a merchant or other trader, he hath not thereby loſt his gentility; and he deſires it may be remembered, for the honour of trade, that king Henry VIII. thought it no diſhonour to him, when he quitted his queen, to take his wife Anne, the daughter of Thomas Bullen, ſometime mayor of London. To which may be added the thought, that the firſt William, who founded our royal race, was the grandſon of a tanner.

GENUS, Gender, in botany, denotes a ſyſtem, or aſſemblage, of ſeveral plants, agreeing in ſome one or more common characters in reſpect of the ſtructure of certain parts; whereby they are diſtinguiſhed from all other plants. The diſtribution of plants into *genera*, and ſpecies, is abſolutely neceſſary to eaſe the memory, and prevent its being oppreſſed, and overburdened with an infinity of different names. The knowledge of a *genus* comprehends, in a kind of miniature, that of all the plants belonging thereto; each being denominated from ſome circumſtance, common to the whole kind, to ſave the embarraſſment of ſo many particular names. See Syſtem of Botany, Sect. V.

Genus is alſo uſed for a character, or manner applicable to every thing of a certain nature or condition. In which ſenſe it ſerves to make capital diviſions in divers ſciences; as muſic, rhetoric, botany, anatomy, and natural hiſtory.

GEOCENTRIC, in aſtronomy, is applied to a plannet or its orbit, to denote it concentric, with the earth, or, as having the earth for its centre, or the ſame centre with the earth.

GEOGRAPHY, formed of γη, *terra*, *earth*; and γραφω, *ſcribo*, *I write*, *I deſcribe*; the doctrine oa knowledge of the earth, both as in itſelf, and as to its affections; or a deſcription of the terreſtrial globe, and, particularly, of the known habitable part thereof, with all its parts. *Geography* may be conſidered as a branch of mathematics, becauſe it conſiders the earth, and its affections, as depending on quantity; and, conſequently, as meaſurable: viz. its figure, place, magnitude, motion, celeſtial appearances, &c. with the ſeveral circles imagined on its ſurface.

The following Syſtem of Geography *is the production of* Mr. Marquois, *Parliament Street, Weſtminſter*.

SYSTEM OF GEOGRAPHY.

HISTORY.

THE Chaldeans and Egyptians, who were diſtinguiſhed by their ſkill in geometry and aſtronomy, were the firſt perſons that paid any particular attention to *geography*; and it is ſaid that the firſt map was made by order of Seſoſtris I. who conquered Egypt. Hiſtorians relate, that the Roman ſenate, about a hundred years before Chriſt, ſent geographers into divers parts to make an accurate ſurvey and menſuration of the whole globe; but they ſcarce ſaw the twentieth part of it.

Before them, Neco king of Egypt, ordered the Phœnicians to make a ſurvey of the whole coaſt of Africa; which they accompliſhed in three years: Darius procured the Ethiopic ſea, and the mouth of the Indus, to be ſurveyed. Thales of Miletus, Anaximander his diſciple, who is ſaid to have conſtructed the firſt ſphere; Democritus, Euxodus, &c. who made uſe of maps common in Greece; Ariſtagoras of Miletus, who preſented to Cleomenes, king of Sparta, a table of braſs, on which he had deſcribed the known earth, with its ſeas and rivers; and other Greeks, availing themſelves of the aſſiſtance derived from the Chaldeans and Egyptians, proſecuted the ſtudy and enlarged the extent of this ſcience. It appears that in the time of Socrates, geographical maps were uſed at Athens, for this philoſopher humbled the pride and boaſt of Alcibiades, by deſiring him to point out his territories in Attica in a map: and Pliny relates, that Alexander, in his expedition into Aſia, took two geographers, Diognetus and Bæton, to meaſure and deſcribe the roads; and that from their itineraries, the writers of the following ages took many particulars.

Pytheas the famous geographer of Marſeilles flouriſhed in the time of Alexander; and Ariſtotle ſeems to have been no leſs converſant with *Geography* than philoſophy: after Alexander, Selucus, Nicanor, Theophraſtus, the diſciple of Ariſtotle, Eratoſthenes, who publiſhed three books of geographical commentaries, and corrected a chart of Anaximander, Hipparchus, who corrected the obſervations of Eratoſthenes, and thus furniſhed occaſion for a diſpute which greatly contributed to the improvement of *geography*. *Geography* was tranſmitted, with the other arts, from Greece to Rome: Polybius, under a commiſſion from Scipio Æmelianus, reconnoitred the coaſts of Africa, Spain, and France, and meaſured the diſtances of all thoſe places which Hannibal had viſited in his march over the Pyrennes and Alps. Varro's works contain many geographical remarks: Zenodoxus, Theodorus and Polycletus were employed under the conſulſhip of Julius Cæſar and Mark Anthony in ſurveying and meaſuring the globe. The commentaries of Cæſar are well known. Auguſtus was a diſtinguiſhed patron and promoter of this ſcience; under whom Strabo publiſhed his *geography*. And the taſte for the ſtudy and advancement of *geography* was greatly encouraged under Tiberius, Claudius, Veſpaſian, Domitian, and Adrian. Iſidore of Charax, who lived to the commencement of the firſt century of the Chriſtian æra; Pomponius Mela, who publiſhed a book intitled De Situ Orbis; Metius Pompoſianus, who, having depicted the earth on a parchment, fell a ſacrifice to the jealouſy of Domitian, the emperor ſuſpecting that he aimed at the empire; Pliny the naturaliſt, who has deſcribed the countries known in his time in the third, fourth, fifth, and ſixth books of his Natural Hiſtory; Marinus the Tyrian, who corrected and enlarged the diſcoveries of preceding geographers; and the emperor Antoninus, deſerve particular mention.

This abſtract of the hiſtory of ancient geographers, notwithſtanding whoſe ſucceſſive labours *geography* was ſtill in a very imperfect ſtate, brings us to a period, about the 150th year of the Chriſtian æra, in which Ptolemy of Alexandria contributed greatly to the improvement of this ſcience, by a more ample and accurate deſcription of the terreſtial globe than any had yet given of it. He availed himſelf of numerous obſervations and ancient charts; he corrected the miſtakes and ſupplied many defects of others; and by reducing the diſtances of places on the earth to degrees and minutes, after the manner of Poſidonius, making uſe of the degrees of longitude and latitude, and ſettling the ſituation of places by aſtronomical obſervations, he reduced *geography* into a regular ſyſtem, and laid a foundation for thoſe farther diſcoveries and improvements, which naturally reſulted from the progreſſive, and at preſent advanced ſtate of geometry, aſtronomy, navigation, and commerce. Many valuable geographical works appeared under Diocleſian, Conſtantius, and Maximian, &c. Under the emperor Theodoſius the provincial and itinerary chart or table, ſince known under the name of Peutinger, was digeſted and formed: and the laſt work, that ought to be claſſed with thoſe of the ancients, was the Notitia Imperii, attributed to Ethicus, who lived between the years 400 and 450 of the Chriſtian æra. The ages of barbariſm ſucceeded the fall of the Roman empire; and the arts and ſciences were obliged to ſeek refuge and protection from the Arabians and Orientaliſts in Aſia; the principal of whom, diſtinguiſhed by their attention to *geography*, were Almamom, caliph of Babylon, and Abulfeda, a Syrian prince. After the revival of learning in Europe, and particularly during the two laſt centuries, *geography* has derived very conſiderable acceſſions from travels, voyages, and a variety of nautical and aſtronomical obſervations. For a fuller account of the hiſtory of ancient *geography*, ſee the preface to Bertius's edition of Ptolemy's Theatrum Geographiæ Veteris, Fol. The ſcience, however muſt needs have been exceedingly defective; as a great part of the globe was then unknown: particularly all America, the northern parts of Europe and Aſia, with the Terra Auſtralis, and Magellanica; and as they were ignorant of the earth's being capable of being ſailed round, and of the torrid zone's being habitable, &c.

The principal writings on this ſcience, among the ancients are, Ptolemy's eight books: the moderns, Johannes De Sacroboſco De Sphæra, with Clavius's comment: Ricciolus's Geographia and Hydrographia Reformata: Weigelius's Speculum Terræ; De Chales's Geography; and above all, Varenius's Geographia generalis, with Jurin's additions, to which may be added, Leibnecht's Elementa Geographiæ generalis; Sturmius's Compendium Geographicum: Wolfius's Geographia, in his Elementa Matheſeos, and Bankes's Geography, with the lateſt diſcoveries.

GEOGRAPHICAL DIVISIONS OF THE EARTH.

In *geography* the different places of the globe are treated of under four grand diviſions, viz. Europe, Aſia, Africa, and America, and theſe are ſubdivided into kingdoms, ſtates, provinces, &c.

EUROPE contains Denmark, Eaſt and Weſt Greenland, Iceland, Norway, Denmark Proper, Lapland, Sweden, Muſcovy or the Ruſſian Empire, Scotland, and the Hebrides, Orkney, England, Wales, Ireland, Iſle of Man, Iſles of Wight, Jerſey, Guernſey, &c. France, United Netherlands, or Holland, Auſtrian and French Netherlands, Germany, Pruſſia, Bohemia, Hungary, Tranſylvania, Sclavonia, and Croatia, Poland and Lithuania, Switzerland, Spain, Portugal, Italy, part of Turkey, Ancient Greece, Turkiſh Iſlands, &c.

ASIA contains part of Turkey, Tartary, China, India, Perſia, Arabia, Indian and Oriental Iſlands, &c. &c.

AFRICA contains Egypt, and the States of Barbary; with all that part of the Globe, from the tropic of Cancer to the Cape of Good Hope, and ſeveral Iſlands.

AMERICA contains New Britain, Canada, Nova Scotia, United States of America, New England, New York, New Jerſey, Penſylvania, Mary-land, Virginia, North and South Carolina, Georgia, Weſt Indies, Jamaica, Eaſt and Weſt Florida, New Mexico, Califormia, Old Mexico, Terra Ferma, Peru, Chil Paraguay, Cuba, Hiſpaniola, Brazil, Cayenne, the Iſlands of Martinico, and Guadaloupe, Surinam, the Iſlands of St. Euſtatia, and St. Thomas's, Terra Incognita, &c. &c.

NATURAL DIVISIONS OF THE EARTH.

The conſtituent parts of the earth are two, the *land* and *water*. The parts of the land are continents, iſlands, peninſulas, iſthmuſes, promontories, capes, coaſts, mountains, &c. The land is divided into two great continents (beſides the iſlands), viz. the *eaſtern* and *weſtern* continent. The eaſtern is ſubdivided into three parts, viz. Europe, on the north-weſt; Aſia, on the north-eaſt; and Africa (which is joined to Aſia by the iſthmus of Suez, 60 miles over), on the ſouth. The weſtern continent conſiſts of North and South America, joined by the iſthmus of Darien, 60 or 70 miles broad. A *continent* is a large portion of land, containing ſeveral countries or kingdoms, without any entire ſeparation of its parts by water, as Europe. An *iſland* is a ſmaller part of land, quite ſurrounded by water, as Great Britain. A *peninſula* is a tract of land every where ſurrounded by water, except at one narrow neck, by which it joins the neighbouring continent; as the Morea in Greece: and that neck of land which ſo joins it, is called an *iſthmus*: as the iſthmus of Suez which joins Africa to Aſia, and the iſthmus of Darien which joins North and South America. A *promontory* is a hill, or point of land, ſtretching itſelf into the Sea, the end of which is called a *cape*; as the Cape of Good Hope. A *coaſt* or *ſhore* is that part of a country which borders on the ſea-ſide. Mountains, vallies, woods, deſarts, plains, &c. need no deſcription. The moſt remarkable are taken notice of, and deſcribed in the ſyſtem. The parts of the water are oceans, ſeas, lakes, ſtraits, gulfs, bays, or creeks, rivers, &c. The waters are divided into three extenſive oceans (beſides leſſer ſeas, which are only branches of theſe), viz. the *Atlantic*, the *Pacific*, and the *Indian* Ocean. The Atlantic, or Weſtern Ocean, divides the eaſtern and weſtern continents, and is 3000 miles wide. The Pacific divides America from Aſia, and is 10,000 miles over. The Indian Ocean lies between the Eaſt Indies and Africa, being 3000 miles wide.

The *ocean* is a great and ſpacious collection of water, without any entire ſeparation of its parts by land; as the Atlantic Ocean. The *ſea* is a ſmaller collection of water, which communicates with the ocean, confined by the land; as the Mediterranean and the Red Sea. A *lake* is a large collection of water, entirely ſurrounded by land; as the lake of Geneva, and the lakes in Canada. A *ſtrait* is a narrow part of the ſea, reſtrained or lying between two ſhores, and opening a paſſage out of one ſea into another; as the ſtrait of Gibraltar, or that of Magellan. This is ſometimes called a *ſound*; as the ſtrait into the Baltic. A *gulf* is a part of the ſea running up into the land, and ſurrounded by it, except at the paſſage whereby it is communicated with the ſea or ocean. If a gulf be very large, it is called an inland ſea; as the Mediterranean; if it do not go far into the land, it is called a *bay*, as the Bay of Biſcay; if it be very ſmall, a *creek*, *haven*, *ſtation*, or *road* for ſhips, as Milford Haven. Rivers, canals, brooks, &c. need no deſcription: for theſe leſſer diviſions of water, like thoſe of land, are to be met with in moſt countries, and every one has a clear idea of what is meant by them.

GEOGRAPHY.

TABLE exhibiting the ſuperficial content of the whole globe in ſquare miles, ſixty to a degree, and alſo of the ſeas and unknown parts, the habitable earth, the four quarters or continents; and the great empires and principal iſlands, placed as they are ſubordinate to one another in magnitude.

To theſe iſlands may be added the following, which have lately been diſcovered, or more fully explored. The exact dimenſions of them are not aſcertained; but they may be arranged in the following order, according to their magnitude, beginning at the largeſt, which is ſuppoſed to be nearly equal in ſize to the whole continent of Europe:

New Holland, New Caledonia, Friendly Iſlands,
New Guinea, New Hebrides, Marqueſas,
New Zealand, Otaheite, Eaſter or Davis's Iſland.

DIVISION I. EUROPE.

Europe, though the leaſt extenſive quarter of the globe, is in many reſpects that which moſt deſerves our attention. Geography diſcovers to us two circumſtances with regard to Europe, which perhaps have had a conſiderable tendency in giving it the ſuperiority over the reſt of the world. Firſt, the happy temperature of its climate, no part of it lying within the torrid zone; and ſecondly, the great variety of its ſurface. The immenſe number of mountains, rivers, ſeas, &c. which divide the different countries of Europe from one another, is likewiſe extremely commodious for its inhabitants. Theſe natural boundaries check the progreſs of conqueſt or deſpotiſm, which has always been ſo rapid in the extenſive plains of Africa and the Eaſt: the ſeas and rivers facilitate the intercourſe and commerce between different nations; and even the barren rocks and mountains are more favourable for exciting human induſtry and invention, than the natural unſolicited luxuriancy of more fertile ſoils. There is no part of Europe ſo diverſified in its ſurface, ſo interrupted by natural boundaries or diviſions, as Greece: and we know that it was there the human mind began to know and to avail itſelf of its ſtrength, and that many of the arts, ſubſervient to utility, or pleaſure, were there invented, or at leaſt greatly improved. What Greece is with regard to Europe, Europe is with regard to the reſt of the globe. We do not however ſpeak of Greece as it is at preſent, under the domination of Turks and unnatural tyranny of Barbarians, but of ancient Greece which was diſtinguiſhed above all the reſt of Europe for the equity of its laws, and the freedom of its political conſtitution; moſt of the European governments are now monarchical, but we may diſcover, on due examination, that there are a thouſand little ſprings, which check the force, and ſoften the rigour of monarchy in Europe, that do not exiſt any where elſe, and the ſpirit of liberty is gaining ground daily. In proportion to the number and force of theſe checks, the monarchies of Europe, ſuch as Ruſſia, France, Spain, and Denmark, differ from one another. Beſides *monarchies*, in which one man bears the chief ſway, there are in Europe, *ariſtocracies* or governments of the nobles, and *democracies* or governments of the people. Venice is an example of the former; Holland, and ſome ſtates of Italy and Switzerland, afford examples of the latter. There are, likewiſe, mixed governments, which cannot be aſſigned to any one claſs. Great Britain, which partakes of all the three, is the moſt ſingular inſtance of this kind we are acquained with. The other mixed governments of Europe are compoſed only of two of the ſimple forms, ſuch as Poland, ſeveral ſtates of Italy, &c. The Chriſtian religion is eſtabliſhed throughout every part of Europe, except Turkey; but from the various capacities of the human mind, and the different lights in which ſpeculative opinions are apt to appear when viewed by perſons of different educations and paſſions, that religion is divided into a number of different ſects, but which may be comprehended under three general denominations; 1ſt, The Greek church; 2d, Popery; and 3d, Proteſtantiſm; which laſt is again divided into Lutheraniſm and Calviniſm, ſo called from Luther and Calvin, the two diſtinguiſhed reformers of the 16th century, and of theſe there are alſo various ſects. The languages of Europe are derived from the ſix following; the Greek, Latin, Teutonic or old German, the Celtic, Sclavonic, and Gothic.

GRAND DIVISIONS OF EUROPE.

This grand diviſion of the earth is ſituated between the 10th degree weſt, and the 65th degree eaſt longitude from London; and between the 36th and 72d degree of north latitude. It is bounded on the north, by the Frozen Ocean; on the eaſt, by Aſia; on the ſouth, by the Mediterranean Sea, which divides it from Africa; and on the weſt, by the Atlantic Ocean, which ſeparates it from America; being 3000 miles long, from Cape St. Vincent in the weſt to the mouth of the river Oby in the north-eaſt; and 2500 broad from north to ſouth, from the north Cape in Norway to Cape Cayha or Metapar in the Morea, the moſt ſouthern promontory in Europe. It contains the following kingdoms and ſtates.

	Kingdoms	Len.	Bth.	Chief City	diſt bearing from Lond.	Dif of time from Lond	Religions.

N. B. In the above Table and what follows, N. ſtands for North, S. for South, E. for Eaſt, and W. for Weſt.

Excluſive of the Britiſh iſles, before mentioned, Europe contains the following principal Iſlands:

Iſlands.		Chief Towns	Subject to
In the Northern Ocean.	Iceland	Skalholt	Denmark
Baltic Sea	Zealand, Funen, Alſon, Falſter, Langland, Laland, Femeren, Mona, Bornholm,	—	Denmark
	Gothland, Aland, Rugen, —	—	Sweden
	Oſel, Dagho, — —	—	Ruſſia
	Uſedom, Wollin, — —	—	Pruſſia
Mediterranean Sea	Ivica, — —	Ivica,	Spain
	Majorca, — —	Majorca	Ditto
	Minorca, — —	PortMahon	Ditto
	Corſica, — —	Baſtia	France
	Sardina, — —	Cagliari	K. of Sard
	Sicily, — —	Palermo	K. of 2 Sic
Adriatic, or Gulf of Venice.	Luſiena, Corfu, Cephalonia, Zant, Leucadia, —	—	Venice
Archipelago, and Levant Seas.	Candia, Rhodes, Negropont, Lemnos, Tenedos, Scyros, Mytelene, Scio, Samos, Patmos, Paros, Cerigo, Santorim, part of ancient & mod. Greece, &c.	—	Turkey

DENMARK.

The dominions of the Daniſh Majeſty are divided into four parts: 1ſt, Eaſt and Weſt Greenland, Iceland, and the iſlands in the Atlantic Ocean; 2d, Norway; 3d, Denmark Proper; and 4th, his German territories.

The dimenſions of theſe countries are as under.

Denmark.		Square Miles.	Length	Breadth	Chief Cities.
Denmark Proper.	North Jutland.	9600	155	98	Wyburg.
	South Jutland, or Sleſwick.	2115	70	63	Sleſwick.
Iſlands at the entrauce of the Baltic Sea.	Zeland,	1935	60	60	COPENHAGEN, N. Lat. 55—41 E. Lon. 12—5
	Funen,	768	38	32	Odenſee.
	Falſter and Langland,	220	27	12	Nikoping. Naxkaw.
	Femeren,	50	13	8	Borge.
	Alſen,	54	15	6	Sonderborge.
	Mona,	39	14	5	Stege.
	Bornholm,	160	20	12	Roſtcomby.
In the N. Seas,	Iceland Iſland.	46000	435	185	Skalholt.
	Norway,	71400	750	170	Bergen.
Daniſh	Lapland,	28400	285	172	Wardhuys.

GEOGRAPHY.

AST AND WEST GREENLAND, ICELAND, AND THE ISLANDS IN THE ATLANTIC OCEAN.

EAST GREENLAND — Or as others call it, New Green- and or the country of Spitzbergen, lie between 9 and 20 deg. E. ong. 76 and 81 deg. N. lat. according to captain Phipps's obſer- ations in his Voyage 1773. It was diſcovered by Sir Hugh Villoughby in 1553; and is ſuppoſed to be a continuation of Old Greenland. It obtained the name of Spitzbergen from the height nd raggedneſs of its rocks. There is a whale-fiſhery, chiefly pro- ecuted by the Dutch and ſome Britiſh veſſels, on its coaſts. It ikewiſe contains two harbours; one called South Haven, and the ther Maurice Bay; but the inland parts are uninhabited.

WEST GREENLAND — Lies between the meridian of Lon- on, and 50 deg. W. long. and between 60 and 76 deg. N. lat. The taking of whales in the ſeas of Greenland, among the fields f ice that have been increaſing for ages, is one of the greateſt cu- oſities in nature. Theſe fields, or pieces of ice, are frequently nore than a mile in length, and upwards of a 100 feet in thick- eſs; and when they are put in motion by a ſtorm, nothing can e more terrible; the Dutch had thirteen ſhips cruſhed to pieces y them in one ſeaſon.

ICELAND — Receives its name from the great maſſes of ice hat are ſeen near it: lies between 63 and 67 deg. N. lat. and be- ween 11 and 27 deg. W. long. It extends four hundred miles n length, and an hundred and ſixty in breadth, containing about 6000 ſquare miles. In April, 1783, the inhabitants of Iceland bſerved ſomething riſen and flaming in the ſea, to the ſouth of Grinbourgh, at eight miles diſtant from the rocks des Oiſeaux, which afterwards was found to be a new iſland. The fact is au- hentic, but its dimenſions and ſituation are not yet well aſcertained. n this Iſland are many volcanoes; the principal, is that called Heckla ſituated in the ſouthern part about four miles from the ſea- oaſt. Its eruptions were particularly dreadful in 1693, when hey occaſioned terrible devaſtations, the aſhes being thrown all ound the iſland to the diſtance of 180 Engliſh miles. But amongſt ll the curioſities in Iceland, nothing is more worthy of attention han the hot ſpouting water-ſprings with which this iſland abounds. n ſeveral of theſe hot ſprings, the inhabitants who live near them oil their victuals, only by placing a pot of cold water, into which he fleſh is put, to a certain depth within the ſpring.

NORWAY. — The natural ſignification of Norway is the *Nor- hernway.* It is bounded on the South by the entrance into the Baltic alled the Scaggerac, or Categate; on the Weſt and North by the orthern ocean; and on the Eaſt it is divided from Sweden by long ridge of mountains, called at different parts by different arts by different names; as Fillefield, Dofrefield, Runfield, and Dourfield. The reader may conſult the table of dimenſions in Denmark for its extent; but it is a country ſo little known to the eſt of Europe, that it is difficult to fix its dimenſions with preci- ion. This is one of the moſt mountainous countries in the world; for it contains a chain of unequal mountains running rom ſouth to north: to paſs that of Hardanger, a man muſt tra- el about ſeventy Engliſh miles; and to paſs others, upwards of ifty. Dofrefield is counted the higheſt mountain perhaps in Eu- ope. Norway contains quarries of excellent marble as well as nany other kinds of ſtones; and the magnet is found in the iron nines. As are cryſtals, granates, amethyſts, agate, thunder ſtones nd eagle-ſtones. There are alſo gold, ſilver, lead, copper, and iron-mines in this country.

DENMARK PROPER, OR JUTLAND, exclusive of the ISLANDS in the BALTIC.

	Miles.		Degrees.
Length	240	lies between	54 and 58 North latitude.
Breadth	114		8 and 11 Eaſt Longitude.

It is divided on the North from Norway by the Scaggerac ſea, nd from Sweden on the Eaſt by the Sound; on the South by Ger- many and the Baltic; and the German ſea divides it from Great Britain on the Weſt. Denmark Proper is divided into two parts: he peninſula of Jutland anciently called *Cimeria Cherſoneſus*, and he iſlands at the entrance of the Baltic, mentioned in the table. t is remarkable, that though all theſe together conſtitute the king- dom of Denmark, yet not any one of them is ſeparately called by hat name. Copenhagen, the metropolis, is in the iſland of Zea- and. In all the northern provinces of Denmark the winters are very ſevere, ſo that the inhabitants often paſs arms of the ſea in ſledges upon the ice; and during the winter all their harbours are frozen up. Copenhagen, ſituated on the fine iſland of Zealand, was ori- inally a ſettlement of ſailors, and firſt founded by ſome wandering fiſhermen in the twelfth century, but is now the metropolis, Co- penhagen has an harbour, formed by a large canal flowing through the city, which admits indeed but only one ſhip to enter at a time, but is capable of containing 500.

HIS DANISH MAJESTY's GERMAN DOMINIONS.

HOLSTEIN, a duchy of Lower Saxony, about 100 miles long nd 50 broad, and a fruitful country, was formerly divided be- ween the empreſs of Ruſſia (termed Ducal Holſtein), the king of Denmark, and the imperial cities of Hamburgh and Lubeck; but on the 16th of November, 1773, the Ducal Holſtein, with all the ights, prerogatives, and territorial ſovereignty, was formerly tranſ- erred to the king of Denmark, by virtue of a treaty between both courts. The famous city of Hamburgh lies, in a geographical ſenſe, in Holſtein; but is an imperial, free, and Hanſeatic city, lying on the verge of that part of Holſtein, called Stormar. It has the ſovereignty of a ſmall diſtrict round it, of about 10 miles circuit; and is one of the moſt flouriſhing commercial towns in Europe. Lubec, an imperial city, with a good harbour, and once the capital of the Hans Towns, and ſtill a rich and populous place, is alſo in this duchy.

LAPLAND.—The northern ſituation of Lapland, and the diviſion of its property, require, before I proceed farther, that I ſhould treat of it under a diſtinct head, and in the ſame method that I obſerve in other countries. The whole country of Lapland extends, ſo far as it is known, from the North Cape in 71° 30′ N. lat. to the White Sea, under the arctic circle. Part of Lapland belongs to the Danes, and is included in the government of Wardhuys; part to the Swedes, which is by far the moſt valuable; and ſome parts in the eaſt, to the Muſcovites or Ruſſians.

That belonging to the Swedes comprehends all the country from the Baltic, to the mountains that ſeparate Norway from Sweden. The Muſcovite part lies towards the Eaſt, between the lake Enarak and the White Sea. The Daniſh Laplanders can be ſaid to be under no regular government. The Swediſh Lapland, therefore, is the object chiefly conſidered by authors in deſcribing this country. It has been generally thought, that the Laplanders are the deſcendants of Finlanders driven out of their own country, and that they take their name from *Lappes*, which ſignifies exiles. Silver and gold mines, as well as thoſe of iron, copper, and lead, have been diſcovered and worked in Lapland to great advantage; beautiful cryſtals are found here, as are ſome Amethiſts and topazes; alſo various ſorts of Mineral ſtones, ſurprizingly poliſhed by the hand of nature; valuable pearls have likewiſe been ſometimes found in theſe rivers, but never in the ſeas.

	Miles. ——	SWEDEN.	—— Degrees.
Length	800	lies between	56 and 69 North latitude.
Breadth	500		10 and 30 Eaſt longitude.

This country is bounded by the Baltic Sea, the Sound, and the Categate, or Scaggerac, on the South; by the impaſſable mountains of Norway, on the Weſt; by Daniſh or Norwegian Lapland, on the North; and by Muſcovy on the Eaſt. It is divided into ſeven provinces: 1. Sweden Proper. 2. Gothland. 3. Livonia. 4. Ingria. (Theſe two laſt provinces belong now, however, to the Ruſſians, having been conquered by Peter the Great, and ceded by poſterior treaties.) 5. Finland. 6. Swediſh Lapland. And 7. The Swediſh iſlands. Great abatements muſt be made for the lakes and unimproved parts of Sweden; which are ſo extenſive, that the habitable part is confined to narrow bounds. The following are the dimenſions given us of this kingdom.

Sweden.	Square Miles	Sum total.	Length.	Breadth,	Capital Cities.
	76,835	228,715			
Sweden Proper —	47,900		342	194	STOCKHOLM. N. Lat. 59—30. E. Long. 19—15.
Gothland — —	25,975		253	160	Calmar.
Schonen — —	2,960	76,835	77	56	Lunden.
Lapland and W. Bothnia —	76,000		420	340	Torne. Uma.
Swediſh Finland, and Eaſt Bothnia	73,000		395	225	Abo. Dajenburgh.
Gothland I.	1000		80	23	Wiſby.
Oeland I.	560	150,560	84	9	Barkholm.
Upper Saxony Pomerania, P.	960		47	24	Stralſund.
Upper Saxony Rugen I.	360	1,320	24	21	Bergen.

Of Sweden Proper, the following are the ſubdiviſions: *Uplandia, Sudermania, Weſtmania, Nericia, Geſtricia, Helſingia, Dalicarlia, Medelpedia, Angermania, Jemptia.*

Of Gothland, the following are the ſubdiviſions: *Eaſt Gothland, Weſt Gothland, Smaland, Wermeland, Dalia, Schonen, Bleking, Halland.*

Of Swediſh Lapland, the following are the ſubdiviſions: *Thorn Lapmark, Kimi Lapmark, Lula Lapmark, Pithia Lapmark, Uma Lapmark.*

The principal places in Weſt Bothnia are Umea, Pitea, and Tornea.

Of Finland, the following are the ſubdiviſions: *Eaſt Bothnia, Cajania, Savoloxia, Nyland, Travaſtia, Finland Proper.*

The Swediſh iſles are *Gothland, Oeland, Aland,* and *Rugen.*

The face of Sweden is pretty ſimilar to thoſe of its neighbouring countries; only it has the advantage of navigable rivers. Sweden produces cryſtals, amethyſts, topazes, porphyry, lapis-lazuli, agate, cornelian, marble, and other foſſils. The chief wealth of Sweden, however, ariſes from her mines of ſilver, copper, lead, and iron. The laſt mentioned metal employs no fewer than 450 forges, hammering-mills, and ſmelting-houſes. A kind of a gold mine has likewiſe been diſcovered in Sweden, but ſo inconſiderable, that from the year 1741 to 1747, it produced only 2,398 gold ducats, each valued at 9s. 4d. ſterling. Their ſeas are the Baltic, and the gulfs of Bothnia and Finland, which are arms of the Baltic; and on the weſt of Sweden are the Categate ſea, and the Sound, a ſtrait about four miles over which divides Sweden from Denmark.

Theſe ſeas have no tides, and are frozen up uſually four months in the year; nor are they ſo ſalt as the ocean, never mixing with it, becauſe a current ſets always out of the Baltic ſea into the ocean. Stockholm is a ſtaple-town, and the capital of the kingdom; it ſtands about 760 miles north-eaſt from London, upon ſix contiguous iſlands, and built upon piles. The caſtle, accommodates the royal court, and the national courts and colleges. The harbour is ſpacious and convenient, though difficult of acceſs, and this city is furniſhed with all the exterior marks of magnificence, and erections for manufactures and commerce that are common to other great European cities.

MUSCOVY, OR THE RUSSIAN EMPIRE IN EUROPE AND ASIA.

Situation and Extent of the Ruſſian Empire in EUROPE.

Miles		Degrees.
Length 1500	lies between	23 and 65 Eaſt longitude.
Breadth 1100		47 and 72 North latitude.

According to the moſt authentic accounts of this mighty empire, it conſiſts of fifteen (Mr. Voltaire ſays ſixteen) provinces or governments; beſides part of Carelia, Eſthonia, Ingria, Livonia, and part of Finland, which were conquered from Sweden; the Crimea, or Crim Tartary, anciently the Taurica Cherſoneſus, a peninſula in the Euxine ſea, ſubject to the Turks formerly, but added in the year 1783 to the Ruſſian empire, with the iſle of Taman, and part of Cuban; alſo the duchy of Courland in Poland, of which the empreſs of Ruſſia has now the entire diſpoſal.

The following Table will give ſome idea of the Ruſſian empire, properly ſo called, or Ruſſia in Europe, with its acquiſitions from Sweden in the preſent century. And alſo of the Ruſſian empire in its moſt extenſive ſenſe; for we muſt alſo include all the acquiſitions in Tartary, now known by the name of Siberia: the whole comprehending the northern parts of Europe and Aſia, ſtretching from the Baltic and Sweden on the Weſt, to Kantſchatka and the Eaſtern Ocean; and on the North, from the Frozen Ocean to the forty-ſeventh degree of latitude, where it is bounded by Poland, Little Tartary, Turkey, Georgia, the Euxine and Caſpian Seas, Great Tartary, Chineſe Tartary, and other unknown regions in Aſia. The country now compriſed under the name of Ruſſia or the Ruſſias, is of an extent nearly equal to all the reſt of Europe, and greater than the Roman empire in the zenith of his power, or the empire of Darius ſubdued by Alexander, or both put together.

	Ruſſian empire In Europe.	Square Miles.	Length.	Breadth.	Chief Cities.
Greek Church	Ruſ. or Muſc	784,650	1160	1050	Moſcow.
	Belgorod,	72,900	375	285	Waronetz.
	Don Coſſacs,	57,000	400	280	Panchina.
	Uk. Coſſacs,	45,000	330	205	Kiow.
	Lapland,	72,000	405	270	Kola.
Conquered from Sweden ſince 1700.	Ruſ. Finland,	41,310	320	180	Wyburg.

	Ingria,	9,100	175	90	PETERSBURGH { N Lat. 60 e. l. 30 25
Seized from the Turks in 1783,	Crim Tart.	8,200	160	15	Kaffa.
	Ruſſian Emp. in Aſia.				
Chriſtians and Idolaters.	Muſco. Tartary & Siberia,	2,000,000	3150	1500	Tobolſky.
	Kalm. Tart.	850,000	2100	750	Aſtrachan.
	Total	4,161,685			

Ruſſia has been alſo ſubdivided into thirty-one Provinces, viz.

Northern Provinces.—1. *Lapland*; 2. *Samoida*; 3. *Ballamorenſkey*, 4. *Meſeen*; 5. *Dwina*; 6. *Syrianes*; 7. *Permia*; 8. *Rubeninſki*; 9. *Belæſeda.*

Middle Provinces.—10. *Rezan*; *or Pereſlaf*; 11. *Belozero*; 12. *Wologda*, 13. *Jeraſlaf*, 14. *Tweer*, 15. *Moſcow*, 16. *Belgorod.*

Eaſtern Provinces.—17. *Bulgar*; 18. *Kaſan*; 19. *Tſcheremiſſi*; 20. *Little Novogrod*; 21. *Don Coſſacs.*

Weſtern Provinces.—22. *Great Novogrod*; 23. *Ruſſian Finland*, 24. *Kexholm*; 25. *Kaleria*; 26. *Ingria.*

Southern Provinces.—27. *Livonia*; 28. *Smolenſko*; 29. *Zernigof*; 30. *Secfſk*; 31. *Ukraine, or country of the Old Coſſacs.*

Mr. Fooke, chaplain to the Britiſh factory at Peterſburgh, who publiſhed an account of Ruſſia, has enumerated the following nations as comprehended in this great empire.

Mongouls, Kalmucs, Tartars, Samoides, Oſtiacs, Burattians, Jakutans, Tunguſians, Voguls, Laplanders, Finns, Lettonians, Eſthonians, Lieffs, Ingrians, Tſcheremiſſes, Tſcouwaſches, Mordvines, Votiaks, Terptyaireis, Tartars of Kaſan and Orenburg, Tartars of Tobolſk, Tartars of Tomſk, Nogayan Tartars, Tartars of the Ob, Tſchoulym Tartars, Katſchintz Tartars, Teleutes, Abinzes, Biryouſſes, Kurilians, Kiſtim and Toulibert Tartars, Vergo Tomſkoi Tartars, Sayun Tartars, Touralinzes, Bougharians, Baſchkirians, Meſtſceraiks, Barabinzes, Kirkguiſians, Beltirians, Yakoutes, Kamtſchadales; and various others: but ſome of which muſt be conſidered rather as diſtinct tribes than as diſtinct nations. As to the names of Ruſſia and Muſcovy, by which this empire is arbitrarily called, they probably are owing to the ancient inhabitants, the Ruſſi, or Boruſſi, and the river Moſca, upon which the ancient capital Moſcow was built.

Ruſſia is in general a flat, level country, except towards the north, where lie the Zimnopoias mountains, thought to be the famous Montes Riphæi of the ancients, now called the Girdle of the Earth. On the weſtern ſide of the Dnieper comes in part of the Carpathian mountains, and between the Black Sea and the Caſpian, mount Caucaſus borders a range of vaſt plains extending on the ſea of Oral. And here we may obſerve, that from Peterſburgh to Pekin, we hardly meet with a mountain on the road through Independent Tartary; and from Peterſburgh to the north part of France, by the road of Dantzic, Hamburgh, and Amſterdam, we ſcarcely can perceive the ſmalleſt hill.

The moſt conſiderable rivers are the Wolga, or Volga, running eaſt and ſouth, which, after traverſing the greateſt part of Muſcovy, and winding a courſe of 3000 Engliſh miles, diſcharges itſelf into the Caſpian ſea; it is not only reckoned the largeſt, but one of the moſt fertile rivers. By means of this extenſive river, the city of Moſcow preſerves a communication, not only with all the ſouthern parts of Ruſſia, but even with Perſia, Georgia, Tartary, and other countries bordering on the Caſpian ſea. The Don, or Tanais, which divides the moſt eaſtern part of Ruſſia from Aſia; and in its courſe towards the eaſt, comes ſo near the Wolga, that the late czar had undertaken to have a communication between them by means of a canal: this grand project, however, was defeated by the irruptions of the Tartars. This river, excluſive of its turnings and windings, diſcharges itſelf into the Palus Mæctis, or ſea of Aſoph, about four hundred miles from its riſe. The Boriſthenes, or Dnieper, which is likewiſe one of the largeſt rivers in Europe, runs through Lithuania, the country of the Zaporog Coſſacs, and that of the Nagaiſch Tartars, and falls into the Euxine, or Black Sea, at Kinburn, near Oczakow; it has thirteen cataracts within a ſmall diſtance.

Peterſburgh, the Emporium of Ruſſia and capital of the province of Ingria, lies at the junction of the Neva with the lake Ladoga, in latitude 60, on both ſides the river Neva between that lake and the bottom of the Finland gulph; it extends about ſix miles every way; and contains every ſtructure for magnificence, the improvement of the arts, revenue, navigation, war, commerce, and the like, that are to be found in the moſt celebrated cities in Europe. The city of Moſcow was formerly the glory of this great empire, and it ſtill continues conſiderable enough to figure among the capitals of Europe. It ſtands on the river from whence it takes its name, in lat. 55-45, and about 1414 miles north-eaſt of London; and though its ſtreets are not regular, it preſents a very pictureſque appearance; for it contains ſuch a number of gardens, groves, lawns, and ſtreams, that it ſeems rather to be a cultivated country than a city.

SCOTLAND AND ITS ADJACENT ISLES.

Before we proceed to the deſcription of this kingdom, we ſhall give ſome account of the iſlands of Shetland, Orkney, and the Hebrides, or Weſtern iſles.

The iſlands of Shetland lie north-eaſt of the Orcades, or Orkney-iſlands, between 60 and 61 degrees of north latitude, and make part of the ſhire of Orkney. The Orcades lie north of Dungſby-head, between 59 and 60 degrees of north latitude; divided from the continent by a tempeſtuous ſtrait called Pentland Frith, 24 miles long and 12 broad. The Hebrides, or Weſtern iſles, are very numerous, and ſome of them large; ſituated between 55 and 59 degrees of north latitude.

The largeſt of the Shetland iſlands, which are forty-ſix in number (though many of them are uninhabited), is Mainland, which is 60 miles in length, and 20 in breadth. Its principal town is Larwick. Skalloway is another town, where the remains of a caſtle are ſtill to be ſeen, and it is the ſeat of a preſbytery. The largeſt of the Orkney iſlands, which are about thirty in number (though ſeveral of them are unpeopled), is called Pomona. Its length is 33 miles, and its breadth, in ſome places, nine. It contains four excellent harbours. The Iſle of Mull, in the Hebrides, is twenty-four miles long, and, in ſome places, almoſt as broad. The other principal weſtern iſland are, Lewis, or Harries, (for they both form but one iſland), which belongs to the ſhire of Roſs, and is 100 miles in length, and 13 or 14 in breadth; its chief town is Stornway. Sky, belonging to the ſhire of Inverneſs, is 40 miles long, and, in ſome places, 30 broad; fruitful and well peopled. Bute, is about ten miles long, and three or four broad. The iſles of Ila and Jura, are part of Argyleſhire, and contain together about 370 ſquare miles. North Uiſt contains an excellent harbour, called Lochmoddy, famous for herring-fiſhing.

Miles. ——	SCOTLAND.	—— Degrees.
Length 300	lies between	54 and 59 North latitude.
Breadth 100		1 and 6 Weſt longitude.

It is termed by the Italians, Scotia; by the Spaniards, Eſcotia: by the French, Eſcoſſe; and Scotland by the Scots, Germans, and Engliſh. Scotland, which contains an aræa of 27,794 ſquare miles, is bounded on the South by England; and on the north, eaſt, and weſt, by the Deucaledonian, German, and Iriſh ſeas, or, more properly, the Atlantic ocean. Scotland is divided into the countries ſouth of the Frith of Forth, the capital of which, and of all the kingdom, is Edinburgh; and thoſe to the north of the ſame river, where the chief town is Aberdeen. This was the ancient national diviſion; but ſome modern writers, with leſs geographical accuracy, have divided it into Highlands and Lowlands, on account of the different habits, manners, and cuſtoms of the inhabitants of each. Eighteen countries, or ſhires, are allotted to the ſouthern diviſion, and 15 to the northern; and thoſe countries are ſubdivided into ſheriffdoms, ſtewarties, and bailiwicks, according to the ancient tenures and privileges of the landholders.

Shires.	Sheriffdoms and other ſubdiviſions.	Chief Towns.
1. Edinburgh	Mid Lothian —	Edinburgh, W. lon. 3. N. lat. 56. Muſſelburgh, Leith, and Dalkeith.
2. Haddington	Eaſt Lothian —	Dunbar, Haddington, and North Berwick.
3. Merſe, anciently Berwick †	The Merches, and Lauderdale —	Dunſe, and Lauder.
4. Roxborough	Tiviotdale, Lidſdale, Eſkdale, and Euſdale,	Jedburgh, Kelſo, and Melros.
5. Selkirk	Ettrick Foreſt —	Selkirk.
6. Peebles	Tweedale —	Peebles.
7. Lanerk	Clydeſdale —	Glaſgow, W. lon. 4-5. N. lat. 55-52. Hamilton, Lanerk, and Rutherglen.

Dyſert, Kirkaldy, Kinghorne, and Burnt Iſland —	1		

The principal mountains in Scotland, are the Grampian hills, which run from eaſt to weſt, from near Aberdeen to Cowal in Argyleſhire, almoſt the whole breadth of the kingdom. Another chain of mountains, called Pentland hills, runs through Lothian and join thoſe of Tweedle. A third, called Lammer Muir, riſe near the eaſtern coaſt, and runs weſtward through the Merſe. Beſides thoſe continued chains among which we may reckon the Cheviot or Tiviot Hills, on the borders of England, Scotland contains many detached mountains, which, from their conical figure, ſometimes goes by the Celtic word *Laws*. Many of them are ſtupendouſly high, and of beautiful forms.

The largeſt river in Scotland is the Forth, which riſes in Montieth near Callendar, and paſſing by Sterling, after a number of beautiful meanders, diſcharges itſelf near Edinburgh into that arm of the German ſea to which it gives the name of Frith of Forth. Second to the Forth is the Tay, which iſſues out of Loch Tay, in Broadalbin, and running ſouth-eaſt, paſſes the town of Perth, and falls into the ſea at Dundee. The Spey, which is called the moſt rapid river in Scotland, iſſues from a lake of the ſame name in Badenoch, and running from ſouth-weſt to north-eaſt, falls into the ſea near Elgin; as do the rivers Dee and Don, which run from weſt to eaſt, and diſembogue themſelves at Aberdeen. The Tweed riſes on the borders of Lanerkſhire, and, after many beautiful ſerpentine turnings, diſcharges itſelf into the ſea at Berwick, where it ſerves as a boundary between Scotland and England, on the eaſtern ſide. The Clyde is a large river on the weſt of Scotland, has its riſe in Annandale, runs north-weſt through the valley of that name, and, after paſſing by Lanerk, Hamilton, the city of Glaſgow, Renfrew, Dunbarton, and Greenock, falls into the Frith of Clyde, oppoſite to the iſle of Bute. Beſides thoſe capital rivers, Scotland contains many of an inferior ſort, well provided with ſalmon, trout, and other fiſhes, which equally enrich and beautify the country.

Edinburgh the capital of Scotland, was built for the benefit of protection from the caſtle, and a more inconvenient ſituation for a capital can ſcarcely be conceived. In former times the town was ſurrounded by water, excepting towards the eaſt; ſo that when the French landed in Scotland, during the regency of Mary of Guiſe, they gave it the name of Liſlebourgh. Leith, which is properly the harbour of Edinburgh, is about two miles diſtant. Glaſgow, in the ſhire of Lanerk, ſituated on a gentle declivity ſloping towards the river Clyde, 44 miles weſt of Edinburgh, is, for population, commerce, and riches, the ſecond city of Scotland, and, conſidering its ſize, the firſt in Great Britain, and perhaps in Europe, as to elegance, regularity, and the beautiful materials of its buildings. Aberdeen bids fair to be the third town in Scotland for improvement and population. It is the capital of a ſhire, to which it gives its name, and contains two towns, New and Old Aberdeen. The former is the ſhire town, and evidently built for the purpoſe of commerce. It is a large well built city, and has a good quay, or tide-harbour.

Miles.		ENGLAND.	Degrees.
Length	380	lies betweeen	50 and 56 North latitude.
Breadth	300		2 Eaſt and 6-20 Weſt longitude.

It is bounded on the North, by that part of the Iſland called Scotland; on the Eaſt, by the German ocean; on the Weſt, by St. George's Channel; and on the South by the Engliſh Channel, which parts it from France, and contains 49,450 ſquare miles. The ſituation, by the ſea waſhing it on three ſides, renders England liable to a great uncertainty of weather, ſo that the inhabitants on part of the ſea-coaſts are often viſited by agues and fevers. On the other hand, it prevents the extremes of heat and cold, to which other places, lying in the ſame degree of latitude, are ſubject; and it is, on that account, friendly to the longivity of the inhabitants in general, eſpecially thoſe who live on a dry ſoil. To this ſituation likewiſe we are to aſcribe that perpetual verdure for which England is remarkable, occaſioned by refreſhing ſhowers, and the warm vapours of the ſea.

Antiquaries are divided with regard to the etymology of the word *England*. In the time of the Romans the whole iſland went by the name of *Britannia*. The word *Brit*, according to Mr. Camden,

---

† Berwick, on the North ſide of the Tweed, belonging formerly to Scotland, and gave name to a county in that kingdom; but it is now formed into a town and county of itſelf, in a political ſenſe diſtinct from England and Scotland, having its own privileges.

den, ſignified painted or ſtained; the ancient inhabitants being famous for painting their bodies; other antiquaries, however, do not agree in this etymology. The weſtern tract of England, which is almoſt ſeparated from the reſt by the rivers Severn and Dee, is called Wales, or the *land of ſtrangers*, becauſe inhabited by the Belgic Gauls, who were driven thither by the Romans, and were ſtrangers to the old natives. When the Romans provinciated England they divided it into,

1. Britannia Prima, which contained the ſouthern parts of the kingdom. 2. Britannia Secunda, containing the weſtern parts, comprehending Wales. And, 3. Maxima Cæſarienſis, which reached from the Trent as far northward as the wall of Severus, between Newcaſtle and Carliſle, and ſometimes as far as that of Adrian in Scotland, between the Forth and Clyde. When the Saxons invaded England about the year 450, and when they were eſtabliſhed in the year 582, their chief leaders appropriated to themſelves, after the manner of the other northern conquerors, the countries which each had been the moſt inſtrumental in conquering; and the whole formed an heptarchy, or political republic, conſiſting of ſeven kingdoms. But in time of war, a chief was choſen out of the ſeven kings; for which reaſon I call it a political republic, its conſtitution greatly reſembling that of ancient Greece.

Kingdoms erected by the Saxons, ſtyled the Saxon Heptarchy.

Kingdoms.	Counties.	Chief Towns.
1. Kent, founded by Hengiſt in 475, and ended in 823.	Kent —	Canterbury.
2. Sou. Saxons founded by Ella in 491, and ended in 600.	Suſſex —	Chicheſter,
	Surry —	Southwark.
3. Eaſt Angles, founded by Uffarin 575, and ended in 793.	Norfolk —	Norwich
	Suffolk —	Bury St. Edmonds,
	Cambridge —	Cambridge,
	With the Iſle of Ely	Ely.
4. We. Saxons, founded by Cerdic 512, and ended in 1060.	Cornwall —	Launceſton
	Devon —	Exeter
	Dorſet —	Dorcheſter
	Somerſet —	Bath
	Wilts —	Saliſbury
	Hants —	Wincheſter
	Berks —	Abingdon.
5. Northumberland, founded by Ida in 574, and ended in 792.	Lancaſter —	Lancaſter
	York —	York
	Durham —	Durham
	Cumberland —	Carliſle
	Weſtmoreland —	Appleby
	Northumberland, and Scotland to the Frith of Edinburgh	Newcaſtle.
6. Eaſt Saxons, founded by Erchewin in 527, and ended in 746.	Eſſex —	London.
	Middleſex, and part of Hertford —	
7. Mercia, founded by Cridda in 582, and ended in 874.	Other part of Hertf.	Hertford
	Glouceſter —	Glouceſter
	Hereford —	Hereford
	Worceſter —	Worceſter
	Warwick —	Warwick
	Leiceſter —	Leiceſter
	Rutland —	Oakham
	Northampton	Northampton
	Lincoln —	Lincoln
	Huntingdon —	Huntingdon
	Bedford —	Bedford
	Buckingham —	Ayleſbury
	Oxford —	Oxford
	Stafford —	Stafford
	Derby —	Derby
	Salop —	Shrewſbury
	Nottingham —	Nottingham
	Cheſter —	Cheſter.

Beſides the 52 counties into which England and Wales are divided, there are counties corporate, conſiſting of certain diſtricts, to which the liberties and juriſdictions peculiar to a county have been granted by royal charter. Thus the city of London is a county diſtinct from Middleſex; the cities of York, Cheſter, Briſtol, Exeter, Norwich, Worceſter, and the towns of Kingſton upon Hull, and Newcaſtle upon Tyne, are counties of themſelves, diſtinct from thoſe in which they lie. The ſame may be ſaid of Berwick upon Tweed, which lies in Scotland, and hath within its juriſdiction, a ſmall territory of two miles on the north ſide of the river. Though England is full of delightful riſing grounds, and the moſt enchanting ſlopes, yet it contains few mountains. The moſt noted are the Peak in Derbyſhire, the Endle in Lancaſhire, the Wolds in Yorkſhire, the Cheviot-hills on the borders of Scotland, the Chiltern in Bucks, Malvern in Worceſterſhire, Corſwold in Glouceſterſhire, the Wrekin in Shropſhire: with thoſe of Plinlimmon and Snowdon in Wales.

The rivers in England add greatly to its beauty, as well as its opulence. The Thames, the nobleſt perhaps in the world, riſes on the confines of Glouceſterſhire, a little S. W. of Cirenceſter, and after receiving the many tributary ſtreams of other rivers, it paſſes to Oxford, then by Abingdon, Wallingford, Reading, Marlow, and Windſor. From thence to Kingſton, where formerly it met the tide, which, ſince the building of Weſtminſter-bridge, is ſaid to flow no higher than Richmond; from whence it flows to London, and after dividing the counties of Kent and Eſſex, it widens in its progreſs, till it falls into the ſea at the Nore, from whence it is navigable for large ſhips to London bridge. The river Medway, which riſes near Tunbridge, falls into the Thames at Sheerneſs, and is navigable for the largeſt ſhips as far as Chatham. The Severn, reckoned the ſecond river for importance in England, and the firſt for rapidity, riſes at Plinlimmon-hill in North Wales; becomes navigable at Welſh-pool; runs eaſt to Shrewſbury; then turning ſouth, viſits Bridgenorth, Worceſter, and Tewkſbury, where it receives the Upper Avon; after having paſſed Glouceſter, it takes a ſouth-weſt direction: is near its mouth increaſed by the Wye and Uſtre, and diſcharges itſelf into the Briſtol Channel, near King-road; and there lie the great ſhips which cannot get up to Briſtol. The Trent riſes in the Moorlands of Staffordſhire, and running ſouth-eaſt by Newcaſtle-under-Line, divides that county into two parts; then turning north-eaſt on the confines of Derbyſhire, viſits Nottingham, running the whole length of that county to Lincolnſhire, and being joined by the Ouſe, and ſeveral other rivers towards the mouth, obtains the name of the Humber, falling into the ſea ſouth-eaſt of Hull.

The other principal rivers in England, are the Ouſe which falls into the Humber, after receiving the water of many other rivers. Another Ouſe riſes in Bucks, and falls into the ſea near Lynn in Norfolk. The Tyne runs from weſt to eaſt through Northumberland, and falls into the German ſea at Tinmouth, below Newcaſtle. The Tees run from weſt to eaſt, dividing Durham from Yorkſhire, and falls into the German ſea below Stockton. The Tweed runs from weſt to eaſt on the borders of Scotland, and falls into the German ſea at Berwick. The Eden runs from ſouth to north through Weſtmoreland and Cumberland, and paſſing by Carliſle, falls into Solway Frith below that city. The Lower Avon runs weſt through Wiltſhire to Bath, and then dividing Somerſetſhire from Glouceſterſhire, runs to Briſtol, falling into the mouth of the Severn below that city. The Derwent, which runs from eaſt to weſt through Cumberland, and paſſing by Cockermouth, falls into the Iriſh ſea a little below. The Ribble, which runs from eaſt to weſt through Lancaſhire, and paſſing by Preſton, diſcharges itſelf into the Iriſh ſea. The Merſey, which runs from the ſouth-eaſt to the north-weſt through Cheſhire, and then dividing Cheſhire from Lancaſhire, paſſes by Liverpool, and falls into the Iriſh ſea a little below that town; and the Dee riſes in Wales, and divides Flintſhire from Cheſhire, falling into the Iriſh channel below Cheſter.

LONDON—The Metropolis of the Britiſh Empire, ſituated in 51°31′ north latitude, 400 miles ſouth of Edinburgh, and 270 ſouth-eaſt of Dublin; 180 miles weſt of Amſterdam, 210 north-weſt of Paris, 500 ſouth-weſt of Copenhagen, 600 miles north-weſt of Vienna, 790 ſouth-weſt of Stockholm, 800 north-eaſt of Madrid, 820 north-weſt of Rome, 850 north-eaſt of Liſbon, 1360 north-weſt of Conſtantinople, 1414 ſouth-weſt of Moſcow. It appears to have been founded between the reigns of Julius Cæſar and Nero, but by whom is uncertain; for we are told by Tacitus, that it was a place of great trade in Nero's time, and ſoon after became the capital of the iſland. It was firſt walled about with hewn ſtones, and Britiſh bricks, by Conſtantine the Great, and the walls formed an oblong ſquare, in compaſs about three miles, with ſeven principal gates. London, in its large ſenſe, including Weſtminſter, Southwark, and part of Middleſex, is a city of a very ſurpriſing extent, of prodigious wealth, and of the moſt extenſive trade. This city, when conſidered with all its advantages, is now what ancient Rome once was; the ſeat of liberty, the encourager of arts, and the admiration of the whole world. London is the centre of trade; it has an intimate connection with all the countries in the kingdom; it is the grand mart of the nation, to which all parts ſend their commodities, from whence they are again ſent back into every town of the nation, and to every part of the world. It is ſituated on the banks of the Thames, a river which though not the largeſt, is the richeſt and moſt commodious for commerce of any in the world. The irregular form of this city makes it difficult to aſcertain its extent. However, its length from eaſt to weſt, is generally allowed to be above ſeven miles, from Hyde-park corner to Poplar, and its breadth in ſome places three, in others two; and in others again not much above half a mile. Hence the circumference of the whole is almoſt 18 miles; or according to a modern meaſurement, the extent of continued buildings, is 35 miles two furlongs and 39 roods. It is much eaſier to form an idea of the large extent of a city ſo irregularly built, by the number of its inhabitants.

N. B. The Meridian of London, is in this ſyſtem made the firſt Meridian, and of courſe has no Longitude; and the Longitudes of the ſeveral places here deſcribed are all computed from the Meridian of London. Briſtol is reckoned the ſecond city in the Britiſh dominions for trade, wealth, and the number of inhabitants. It ſtands upon the north and ſouth ſides of the river Avon, and the two parts of the city are connected by a ſtone bridge.

Part of this city is in Glouceſterſhire, and part in Somerſetſhire. York is a city of great antiquity, pleaſantly ſituated on the river Ouſe; it is very populous, and ſurrounded with a good wall, through which are four gates, and five poſterns. It is the capital of Yorkſhire, 198 miles diſtant from London. The city of Exeter was for ſome time the ſeat of the Weſt-Saxon kings; and the walls, which at this time encloſe it, were built by king Athelſtan, who encompaſſed it alſo with a ditch. It is one of the firſt cities in England, as well on account of its buildings and wealth as its extent and the number of its inhabitants. It has ſix gates, and, including its ſuburbs, is more than two miles in circumference. It is the capital city of Devonſhire, ſituate on the River Ex, 170 miles diſtant from London, in Latitude 50' 44' N. and Longitude 3°: 34½' W. being 10 miles North of the Britiſh Channel. The city of Glouceſter ſtands on a pleaſant hill, with houſes on every deſcent, and is a clean, well-built town, with the Severn on one ſide, a branch of which brings ſhips up to it. It is 104 miles diſtant from London. Litchfield ſtands in a valley, three miles ſouth of the Trent, and is divided by a ſtream which runs into that river. It is 119 miles diſtant from London. Cheſter is a large, populace, and wealthy city, with a noble bridge, that has a gate at each end, and twelve arches over the Dee, which falls into the ſea. The walls were firſt erected by Edelfleda, a Mercian lady, in the year 908, and join on the ſouth ſide of the city to the caſtle, from whence there is a pleaſant walk round the city upon the walls, except where it is intercepted by ſome of the towers over the gates: and from whence there is a proſpect of Flintſhire, and the mountains of Wales. It is the capital of Cheſhire, 182 miles diſtant from London. Warwick is the county town of Warwickſhire, and appears to have been of eminence even in the time of the Romans. It ſtands upon a rock of free-ſtone, on the banks of the Avon; and a way is cut to it through the rocks from each of the four cardinal points. The town is populous, and the ſtreets are ſpacious and regular, and all meet in the centre of the town. It is 105 miles N. W. from London. The city of Coventry is large and populous, it has a handſome town-houſe, and twelve noble gates. The City, with the Territories about it, is a county of itſelf; it is 91 miles diſtant from London.

Saliſbury is a large, neat, and well-built city, ſituated in a valley, and watered by the Upper Avon on the Weſt and ſouth, and by the Bourne on the eaſt. The ſtreets are generally ſpacious, and built at right angles. It is 80 miles diſtant from London. The city of Bath took its name from ſome natural hot baths, for the medicinal waters of which this place has been long celebrated, and much frequented. It is ſituate on the River Avon, in Somerſetſhire, 108 miles diſtant from London. Nottingham, the county of Nottinghamſhire, is pleaſantly ſituated on the aſcent of a rock, overlooking the river Trent, which runs parallel with it about a mile to the ſouth, and has been made navigable. It is one of the neateſt places in England, and has a conſiderable trade. It is 122 miles North of London. No nation in the world can ſhew ſuch dock-yards, and all conveniences for the conſtruction and repairs of the royal navy, as Portſmouth, (the moſt regular fortification in England), Plymouth (by far the beſt dock-yard), Chatham, Woolwich, and Deptford. Every town in England is noted for ſome particular production or manufacture, to which its building and appearance are generally fitted; and though England contains many excellent and commodious ſea-ports, yet all of them have an immediate connection with London, which is the common centre of national commerce.

WALES. — As the principality of Wales is peculiar in language and manners, though in a political ſenſe forming a part of England; we have therefore treated it in a ſeparate point of view.

	Miles.		Degrees.
Length	130	lies between	51 and 54 North latitude.
Breadth	96		2-41 and 4-56 Weſt longitude.

Area in ſquare miles 7011.—Wales was formerly of greater extent than it is at preſent, being bounded only by the Severn and the Dee; but after the Saxons had made themſelves maſters of all the plain country, the Welch, or ancient Britons, were ſhut up within more narrow bounds, and obliged gradually to retreat weſtward. It does not however appear, that the Saxons ever made any farther conqueſts in their country than Monmouthſhire and Herefordſhire, which are now reckoned part of England. Wales towards the north is mountainous, but contains rich vallies. This country is well ſupplied with wholeſome ſprings; and its chief rivers are the Clywd, the Wheeler, the Dee, the Severn, the Elwy, and the Alen, which furniſh Flintſhire with great quantities of fiſh.

Wales contains no cities or towns that are remarkable either for populouſneſs or magnificence. At a ſmall village called Newton, in Glamorganſhire, is a remarkable ſpring nigh the ſea, which ebbs and flows contrary to the ſea. In Flintſhire is a famous well, known by the name of St. Winifred's Well, at which, it is ſaid, miraculous cures have been performed. The ſpring boils with vaſt impetuoſity out of a rock, and is formed into a beautiful polygonal wall, covered with a rich arch ſupported by pillars, and the roof is moſt exquiſitely carved in ſtone. The ſpring is ſuppoſed to be one of the fineſt in the Britiſh dominions; and by two different trials and calculations lately made, is found to fling out about twenty-one tons of water in a minute. It never freezes, or ſcarcely varies in the quantity of water in droughts or after the greateſt rains. The ſmall town adjoining to the well, is known by the name of Holywell. Carnarvonſhire is the high mountains of Penmanmawr.

IRELAND. — The iſland of Ireland is ſituated on the weſt ſide of England, between 6 and 10 degrees weſt longitude, and between 51 and 55 degrees 20 minutes north latitude. The extent or ſuperficial content of this kingdom, is, from the neareſt computation and ſurvey, found to be in length 285 miles from Fairhead north, to Miſſenhead ſouth; and from the eaſt part of Down, to the weſt part of Mayo, its greateſt breadth 160 miles, and to contain 11,067,712 Iriſh plantation acres, which make 17,927,864 acres of Engliſh ſtatute meaſure, and is held to bear proportion to England and Wales as 18 to 30. Mr. Templeman, who makes the length 275, and the breadth 150 miles, gives it an ærea of 27,457 ſquare miles. From the eaſt part of Wexford to St. David's in Wales, it is reckoned 45 miles, but the paſſage between Donaghadee and Portpatrick in Scotland is little more than 20 miles, and the paſſage from Holyhead in North Wales about 52 miles.

More conjectures as to the Latin (Hibernia) the Iriſh (Erin) as well as the Engliſh name of this iſland have been formed than the ſubject deſerves. It probable takes its riſe from a Phœnician or Gallic term, ſignifying the fartheſt habitation weſtward. It is extraordinary, that even modern authors are not agreed as to the diviſions of Ireland; ſome dividing it into five circuits, and ſome into four provinces, thoſe of Leinſter, Ulſter, Connaught, and Munſter. I ſhall follow the laſt diviſion, as being the moſt common, and likewiſe the moſt ancient.

PROVINCE OF LESTER, 12 COUNTIES.

Kerry	Tralee	Waterford	Waterford.

The ſoil is rocky, but extremely fertile, when properly cultivated. The bogs of Ireland are very extenſive: that of Allen extends 80 miles, and is computed to contain 300,000 acres. There are others alſo which are very extenſive, and ſmaller ones ſcattered over the whole kingdom. The numerous rivers, enchanting lakes, ſpacious bays, commodious havens, harbours, and creeks, with which Ireland abounds, greatly enrich and beautify this country The Shannon iſſues from Lough Allen, in the county of Leitrim, ſerves as a boundary between Connaught and the three other provinces, and after a courſe of 150 miles, forming in its progreſs many beautiful lakes, it falls into the Atlantic Ocean, between Kerry-point and Loop-head, where it is nine miles broad. The Ban falls into the ocean near Colerain; the Boyne falls into St. George's channel at Drogheda, as does the Liffey at the bay of Dublin, and is only remarkable for watering that capital where it forms a ſpacious harbour. The Barrow, the Nore, and the Suir, water the ſouth part of the kingdom, and, after uniting their ſtreams below Roſs, they fall into the channel at Waterford haven. Dublin, the capital of Ireland, is in magnitude and the number of inhabitants, the ſecond city in the Britiſh dominions. It is ſituated 270 miles north-weſt of London, and near ſixty miles weſt from Holyhead in North Wales, the uſual ſtation of the paſſage-veſſels between Great Britain and Ireland. Dublin ſtands about ſeven miles from the ſea, at the bottom of a large and ſpacious bay, to which it gives name, upon the river Liffey, which divides it almoſt into two equal parts, and is banked in through the whole length of the city, on both ſides, which form ſpacious and noble quays, where veſſels below the bridge load and unload before the merchants doors and warehouſes.

The river Liffey, though navigable for ſea veſſels as far as the cuſtom-houſe, or centre of the city, is but ſmall, when compared with the Thames of London. Cork is deſervedly reckoned the ſecond city in Ireland, in magnitude, riches, and commerce. It lies 129 miles ſouth-weſt of Dublin. Its haven is deep, and well ſheltered from all winds; but ſmall veſſels only can come up to the city, which ſtands about ſeven miles up the river Lee. Waterford, is a city of conſiderable extent, trade, and opulence, and has one of the fineſt quays in Europe, beſides a cathedral, cuſtom-houſe, and other ſpacious buildings. Belfaſt is a large ſea-port and trading town at the mouth of the Lagen water, where it falls into Carrickfergus bay. Downpatrick has a flouriſhing linen manufacture. Carrickfergus (or Knockfergus) the capital town of the province, has a good harbour and caſtle, but little commerce. Derry (or Londonderry, as it is moſt uſually called) ſtands in Lough-Foyl, is a ſtrong little city, having linen manufactures, with ſome commerce and ſhipping. All this extreme north part of Ireland is ſituated ſo near to Scotland, that they are in ſight of each others coaſts. Donegall, the county town of the ſame name (otherwiſe called the county of Tyrconnel), is a place of ſome trade; as is likewiſe Enniſkilling.

ISLE OF MAN. — The Mona mentioned by Tacitus was the iſle of Angleſea, not this iſland. Some think it takes its name from the Saxon word *Mang* (or among), becauſe lying in St. George's Channel, it is almoſt at an equal diſtance from the kingdoms of England, Scotland, and Ireland; but Mona ſeems to have been a generical name with the ancients for any detached iſland. Its length from north to ſouth is rather more than thirty miles, its breadth from eight to fifteen; and the latitude of the middle of the iſland is fifty-four degrees ſixteen minutes north. It is ſaid, that on a clear day the three Britannic kingdoms may be ſeen from this iſland. The air here is wholeſome, and the climate, only making allowance for the ſituation, pretty much the ſame as that in the north of England, from which it does not differ much in other reſpects. The hilly parts are barren, and the champaign fruitful in wheat, barley, oats, rye, flax, hemp, roots, and pulſe. The ridge of mountains, which, as it were, divides the iſland, both protects and fertilizes the vallies, where there is good paſturage. The Iſle of Man contains ſeventeen pariſhes, and four towns on the ſea coaſts. Caſtle town is the metropolis of the iſland, and the ſeat of its goverment; Peele, which of late years begins to flouriſh; Douglas has the beſt market and beſt trade in the iſland, and is the richeſt and moſt populous town, on account of its excellent harbour, and its fine mole, extending into the ſea; Ramſey has likewiſe a conſiderable commerce, on account of its ſpacious bay, in which ſhips may ride ſafe from all winds excepting the north-eaſt.

ISLE OF WIGHT. — This iſland is ſituated oppoſite the coaſt of Hampſhire, from which it is ſeparated by a channel, varying in breadth from two to ſeven miles: it is conſidered as part of the county of Southampton, and is within the dioceſe of Wincheſter. Its greateſt length, extending from eaſt to weſt, meaſures nearly twenty-three miles; its breadth from north to ſouth above thirteen. The air is in general healthy, particularly the ſouthern parts; the ſoil is various, but ſo great is its fertility, it was many years ago computed, that more wheat was grown here in one year, than could be conſumed by the inhabitants in eight: and it is ſuppoſed that its preſent produce, under the great improvements of agriculture, and the additional quantity of land lately brought into tillage, has more than kept pace with the increaſe of population. A range of hills, which affords fine paſture for ſheep, extends from eaſt to weſt, through the middle of the iſland. The interior parts of the iſland, as well as its extremities, afford a great number of beautiful and picturеſque proſpects, not only in the paſtoral, but alſo in the great and romantic ſtyle. The iſland is divided into thirty pariſhes; the town of Newport ſtands nearly in the centre of the iſland, of which it may be conſidered as the capital. The river Medina empties itſelf into the channel at Cowes harbour, diſtant about five miles, and being navigable up to the quay, renders it commodious for trade.

SCILLY ISLES, anciently the SILURES, — Are a cluſter of dangerous rocks, to the number of 140, lying about 30 miles from the Land's End in Cornwall, of which county they were reckoned a part. By their ſituation between the Engliſh channel and St. George's channel, they have been the deſtruction of many ſhips and lives. Some of the iſlands are well inhabited, and have large and ſecure harbours.

In the Engliſh channel are four iſlands ſubject to England: theſe are Jerſey, Guernſey, Alderney, and Sark; which, though they lie much nearer to the coaſt of Normandy than to that of England, are within the dioceſe of Wincheſter. They lie in a cluſter in Mount Saint Michael's bay, between Cape la Hogue in Normandy and Cape Frebelle in Britanny. The computed diſtance between Jerſey and Sark is four leagues; between that and Guernſey, ſeven leagues; and between the ſame and Alderney, nine leagues.

JERSEY, anciently CÆSAREA, — Was known to the Romans; and lies fartheſt within the bay, in 49 degrees 7 minutes north lat. and in the 2d degree 26 minutes weſt longitude, 18 miles weſt of Normandy, and 84 miles ſouth of Portland. The north ſide is inacceſſible through lofty cliffs, the ſouth is almoſt level with the water; the higher land, in its midland part, is well planned, and abounds with orchards, and the vallies are fruitful and well cultivated. The iſland is not above twelve miles in length; but the air is ſo ſalubrious, that, in Camden's time, it was ſaid there was here no buſineſs for a phyſician.

GUERNSEY — Is thirteen miles and a half from ſouth-weſt to north-eaſt, and twelve and a half where broadeſt, eaſt and weſt; has only ten pariſhes, to which there are but eight miniſters, four of the pariſhes being united, and Alderney and Sark, which are appendages of Guernſey, having one a-piece. Though this is a much finer iſland than that of Jerſey, yet it is far leſs valuable; becauſe it is not ſo well cultivated, nor is it ſo populous. Want of firing is the greateſt inconveniency that both iſlands labour under. The only harbour here is at St. Peter le Port, which is guarded by two forts; one called the Old Caſtle, and the other Caſtle Cornet. Guernſey is likewiſe part of the ancient Norman patrimony.

ALDERNEY — Is about eight miles in compaſs, and is by much the neareſt of all theſe iſlands to Normandy, from which it is ſeparated by a narrow ſtrait, called the Race of Alderney, which is a dangerous paſſage in ſtormy weather, when the currents meet; otherwiſe it is ſafe, and has depth of water for the largeſt ſhips.

SARK — Is a ſmall iſland depending upon Guernſey; the inhabitants are long lived, and enjoy from nature all the conveniencies of life. The religion of all the four iſlands is that of the church of England.

FRANCE.

Miles. —— FRANCE. —— Degrees.
Length 600 } lies between { 5 Weſt and 8 Eaſt longitude.
Breadth 500 } lies between { 42 and 51 North latitude.

It is bounded by the Engliſh channel and the Netherlands, on the North; by Germany, Switzerland, and Italy, Eaſt; by the Mediterranean and the Pyrenean mountains, which divide it from Spain, South; and by the bay of Biſcay, Weſt.

This Kingdom is divided, and the Dimenſions of the ſeveral Parts are diſtinctly ſpecified in the following TABLE:

France	Countries Names.	Square Miles.	Length.	Breadth.	Chief Cities.
Papiſts	Orleannois	22,950	230	180	Orleans
	Guienne	12,800	216	122	Bourdeaux
	Gaſcoigne	8,800	125	90	Aux, or Augh
	Languedoc	13,175	200	115	Thoulouſe
	Lyonnois	12,500	175	130	Lyons
	Champagne	10,000	140	110	Rheims
	Bretagne	9,100	170	105	Rennes
	Normandy	8,200	155	85	Rouen
	Provence	6,800	95	92	Aix
	Burgundy	6,700	150	86	Dijon
	Dauphine	5,820	107	90	Grenoble
	Iſle of France	5,200	100	85	PARIS { N. Lat. 48-57 E. Lon. 2-25
	Franche Compte	4,000	100	60	Beſançon
	Picardy	3,650	120	87	Amiens
	Rouſſillon	1,400	50	44	Perpignan
Netherlands	Artois	990	63	32	Arras
	Hainault	800	57	22	Valenciennes
	Flanders	760	58	22	Liſle
	Luxemburg	292	48	13	Thionville
Germany	Lorrain	2,500	—	—	Metz
	Alſace	2,250	95	30	Straſburgh
	Total	138,687			

To theſe is to be added the iſland of Corſica; but the city of Avignon with the Venaiſſin, was in 1774 ceded to the Pope.

France took its name from the Francs, or *Freemen*, a German nation, reſtleſs and enterpriſing, who conquered the Gauls, the ancient inhabitants; and the Roman force not being able to repreſs them, they were permitted to ſettle in the country by treaty. By its ſituation, it is the moſt compact kingdom perhaps in the world, and well fitted for every purpoſe both of power and commerce: and ſince the beginning of the 15th century, the inhabitants have availed themſelves of many of their natural advantages. France is happy in an excellent ſoil, which produces corn, wine, oil, and almoſt every luxury of life. Some of their fruits have a higher flavour than thoſe of England; but neither the paſturage nor tillage are comparable to ours. The chief mountains in France, or its borders, are the Alps, which divide France from Italy: the Pyrenees, which divide France from Spain: Vauge, which divide Lorrain from Burgundy and Alſace; Mount Jura, which divides Franche Compté from Switzerland: the Cevenes, in the province of Languedoc; and Mount Dor in the province of Auvergne. The principal rivers in France are the Loire, the Rhone, the Garonne, and the Seine. The Loire takes its courſe north and north-weſt, being, with all its windings, from its ſource to the ſea, computed to run about 500 miles. The Rhone flows on the ſouth-weſt to Lyons, and then runs on due ſouth till it falls into the Mediterranean. The Garonne riſes in the Pyrenean mountains, takes its courſe, firſt north eaſt, and has a communication with the Mediterranean by means of a canal, the work of Lewis XIV. The Seine, ſoon after its riſe, runs to the north-weſt, viſiting Troyes, Paris, and Rouen, in its way, and falls into the Engliſh channel at Havre. To theſe we may add the Soane, which falls into the Rhone at Lyons; the Charente, which riſes near Havre de Grace, and diſcharges itſelf into the Bay of Biſcay at Rochfort. The Rhine, which riſes in Switzerland, is the eaſtern boundary between France and Germany, and receives the Moſelle and the Sarte in its paſſage. The Somme, which runs north-weſt through Picardy, and falls into the Engliſh channel below Abbeville. The Var, which riſes in the Alps, and runs ſouth, dividing France from Italy, and falling into the Mediterranean, weſt of Nice. The Adour runs from eaſt to weſt, through Gaſcoigne, and falls into the Bay of Biſcay, below Bayonne. Few lakes are found in this country. There is one at the top of a hill near Alegre, which the vulgar report to be bottomleſs, and one at La Beſſe, in which if you throw a ſtone, it cauſes a noiſe like thunder.

Cities and towns are very numerous in France; of which we ſhall mention only Paris, Liſle, and their principal ſea ports, Breſt, and Toulon. Liſle, in French Flanders, is thought to be the moſt regular and ſtrongeſt fortification in Europe, and was the maſter-piece of the famous Vauban. Moving ſouthward, we come to the Iſle of France; the capital of which, and of the whole kingdom, is Paris. This city has been ſo often deſcribed, it may appear ſuperfluous to mention it more particularly, were it not that the vanity of the French has given it a preference, which it by no means deſerves, to all the capitals in the world, in every reſpect. The city of Paris is ſaid to be fifteen miles in circumference. The ſtreets are very narrow, and the houſes very high, many of them ſeven ſtories. The houſes are built of ſtone, and are generally mean, even to wretchedneſs, owing partly to their containing a different family on every floor. The river Seine, which runs through the centre of the city, is not half ſo large as the Thames at London; it is too far diſtant from the ſea for the purpoſes of navigation, and is not furniſhed, as the Thames, with veſſels or boats of any ſort; over it are many ſtone and wooden bridges, which have nothing to recommend them.

The environs of Paris are very pleaſant, and contain a number of fine ſeats, ſmall towns, and villages; ſome of them, being ſcattered on the edges of lofty mountains riſing from the Seine, are remarkably delightful. The palace of Verſailles, ſtands twelve miles from Paris, and is magnificent and expenſive beyond conception, and adorned with all that art can furniſh. Breſt is a ſmall, but very ſtrong town; upon the Engliſh channel, with a moſt ſpacious and fine fortified road and harbour, the beſt and ſafeſt in all the kingdom: yet its entrance is difficult, by reaſon of many rocks lying under water. Lewis XIV. rendered Toulon, from a pitiful village, a ſea-port of great importance. He fortified both the town and harbour, for the reception and protection of the navy royal. Its old and its new harbour lie contiguous; and by means of a canal, ſhips paſs from the one to the other, both of them having an outlet into the ſpacious outer harbour.

NETHERLANDS. — The ſeventeen provinces, which are known by the name of the Netherlands, were formerly part of Gallia Belgica, and afterwards of the circle of Belgium or Burgundy, in the German empire. They obtained the general name of Netherlands, Pais-Bas, or Low-Countries, from their ſituation in reſpect of Germany.

Miles.		Degrees.
Length 360	lie between	49 and 54 North lat.
Breadth 260		2 and 7 Eaſt lon.

They are bounded by the German ſea on the North; by Germany, Eaſt; by Lorrain and France, South; and by the Britiſh Channel, Weſt. We ſhall, for the ſake of perſpicuity, and to avoid repetition, treat of the ſeventeen provinces under two great diviſions: firſt, the *Northern* which contains the ſeven United Provinces, uſually known by the name of HOLLAND: ſecondly, the *Southern*, containing the Auſtrian and French Netherlands. The United Provinces are, properly ſpeaking, eight, viz. Holland, Overyſſel, Zealand, Frieſland, Utretcht, Groningen, Gelderland, and Zutphen; but the two latter forming only one ſovereignty, they generally go by the name of the Seven United Provinces.

Length 150 Breadth nearly the ſame.	lie between	51 and 54 North lat. 2 and 7 Eaſt lon.

The following is the moſt ſatisfactory account we meet with of their geographical diviſion, including the Texel, and other iſlands.

	Countries Names. United Provinces.	Square Miles.	Length.	Breadth.	Chief Cities.
Calviniſts.	Overyſſel	1,900	66	50	Deventer
	Holland	1,800	84	52	AMSTERDAM
	Gelderland	986	50	40	Nimeguen
	Frieſland	810	44	34	Leuwarden
	Zutphen	644	37	33	Zutphen
	Groningen	540	45	37	Groningen
	Utrecht	450	41	22	Utrecht
	Zealand	303	29	24	Middleburg
	Texel and other iſlands	113			
		7,546			

Theſe provinces lie oppoſite to England, at the diſtance of 90 miles, upon the eaſt ſide of the Engliſh channel, and are only a narrow ſlip of low ſwampy land, lying between the mouths of ſeveral great rivers, and what the induſtry of the inhabitants have gained from the ſea by means of dykes, which they have raiſed and ſtill ſupport with incredible labour and expence. The air of the United Provinces is therefore foggy and groſs, until it is purified by the froſt in winter, when the eaſt wind uſually ſets in for about four months, and their harbours are frozen up. The rivers are an important conſideration to the United Provinces; the chief of which are the Rhine, one of the largeſt and fineſt rivers in Europe; the Maeſe, the Scheld, and the Vecht. There are many ſmall rivers that join theſe, and a prodigious number of canals; but there are few good harbours in the United Provinces; the beſt, are thoſe of Rotterdam, Helvoetſluys, and Fluſhing; that of Amſterdam, though one of the largeſt in Europe, has a bar at the entrance of it, over which large veſſels cannot paſs without being lightened. Amſterdam, which is built upon piles of wood, is thought to be, (next to London), the moſt commercial city in the world. Its conveniency for commerce, and the grandeur of its public works, are almoſt beyond deſcription. In this, and all other cities of the United Provinces, the beauty of the canals, and walks under trees planted on their borders, are admirable; but above all, we are ſtruck with the neatneſs and cleanlineſs that is every where obſerved within doors. This city, however, labours under two great diſadvantages: bad air, and the want of freſh wholeſome water, which obliges the inhabitants to preſerve the rain water, in reſervoirs. Rotterdam is the next to Amſterdam for commerce and wealth. The Hague, though but a village, is the ſeat of government in the United Provinces, and is celebrated for the magnificence and beauty of its buildings, the reſort of foreign ambaſſadors and ſtrangers of all diſtinction who live in it, the abundance and cheapneſs of its proviſions, and the politeneſs of its inhabitants: it is no place of trade, but it has been for many years noted as an emporium of pleaſure and politics. Leyden and Utrecht are fine cities, as well as famous for their univerſities. Saardam, though a wealthy trading place, is mentioned here as the workſhop where Peter the Great of Muſcovy, in perſon, ſerved his apprenticeſhip to ſhip-building, and laboured as a common handicraft. The upper part of Gelderland is ſubject to Pruſſia, and the capital city of Gelder.

AUSTRIAN AND FRENCH NETHERLANDS.

Miles.		Degrees.
Length 200	lie between	49 and 52 North latitude.
Breadth 200		2 and 7 Eaſt longitude.

PICARDY— Is bounded by the United Provinces on the North; by Germany, Eaſt; by Lorrain, Champaign, and Picardy, in France, South; and by another part of Picardy, and the Engliſh sea, Weſt. As this country belongs to three different powers, the Auſtrians, French, and Dutch, we ſhall be more particular in diſtinguiſhing the provinces and towns belonging to each ſtate.

I. PROVINCE OF BRABANT.

Subdiviſions.	Chief Towns.	Sq. M.
1. Dutch Brabant.	Boiſleduc, Breda, Bergen op-Zoom, N. Grave, N. E. Lillo, Steenbergen, N. W.	1374
2. Auſtrian Brabant.	Bruſſels, E. lon. 4 deg. 6. min. N. lat. 50-50. Louvain, Vilvorden, Landen, in the middle.	1892

II. PROVINCE OF ANTWERP. —And, III. PROVINCE OF MALINES — Are independent of Brabant, though ſurrounded by it, and ſubject to the houſe of Auſtria.

IV. PROVINCE OF LIMBURG, S. E.

Chief Towns	Limburg, E. lon. 6-5. N. lat. 50-37. ſubject to Auſtria. —	312
	Maeſtricht, Dalem, Fauquemont, or Valburgh, ſubject to the Dutch. —	300

V. PROVINCE OF LUXEMBURG.

Auſtrian Luxemburg.	Luxemburg, E. lon. 6-8. N. lat. 49-45.	2408
French Luxemburg —	Thionville Montmedy S. E.	292

VI. *Province of* NAMUR, *in the Middle, ſubject to* Auſtria.

Chief Towns	Namur, on the Sambre and Maeſe, E. lon. 4-50. N. lat. 50-30. Charleroy on the Sambre	425

VII. PROVINCE OF HAINAULT.

Auſtrian Hainault	Mons, E. lon. 3-33. N. lat. 50-30. Aeth, Enguien, in the middle —	640
French Hainault	Valenciennes, Bouchain, Conde, Landrechy, S. W. — —	800

VIII. PROVINCE OF CAMBRESIS.

Subject to France	Cambray E. of Arras, E. lon. 3-15. N. lat. 50-15. Crevecour, S. of Cambray	150

IX. PROVINCE OF ARTOIS.

Subject to France	Arras, S. W. on the Scarpe, E. lon. 2-15. N. lat. 50-20. St. Omer, E. of Boulogne, Aire, S. of St. Omer, S. Venant, E. of Aire Bethune, S. E. of Aire, Terouen, S. of St. Omer	990

X. PROVINCE OF FLANDERS.

Dutch Flanders.	Sluys, Axel, Hulſt, Sas van Ghent, N.	280
Auſtrian Flanders	Ghent on the Scheld, E. Lon. 3-36. N. lat. 51. Bruges, Oſtend, Newport, N. W. near the ſea. Oudenard on the Scheld; Courtray, Dixmud, on the Lis Ypres, N. of Liſle; Tourney on the Scheld; Menis on the Lis.	1905
French Flanders	Liſle, W. of Tournay; Dunkirk, on the coaſt E of Calais; Douay, W. of Arras; Mardike, W. of Dunkirk; St. Amand, N. of Valenciennes; Gravelin, E. of Calais —	760

The air of Brabant, and upon the coaſt of Flanders, is bad; that in the interior parts is more healthful, and the ſeaſons more ſettled, both in winter and ſummer, than they are in England. The ſoil and its produce are rich, eſpecially in corn and fruits. They have abundance of paſture; and Flanders itſelf has been reckoned the granary of France and Germany. The chief rivers are the Maeſe, Sambre, Demer, Dyle, Nethe, Geer, Saune, Ruppel, Scheld, Lis, Scarpe, Deule, and Deneer.

The walls of Ghent, formerly the capital of Flanders, and celebrated for its linen and woollen manufactures, contain the circuit of ten miles; but now unoccupied, and great part of it in a manner void. Bruges, formerly ſo noted for its trade and manufactures, and fine canals, is now dwindled to an inconſiderable place. Oſtend is a tolerably convenient harbour for traders; Ypres, is only a ſtrong garriſon town. The ſame may be ſaid of Charlcroy and Namur. Louvain, the capital of the Auſtrian Brabant, inſtead of its flouriſhing manufactures and places of trade, now only contains handſome gardens, walks, and harbours. Bruſſels retains ſomewhat of its ancient manufactures; and being the reſidence of the governor or viceroy of the Auſtrian Netherlands, it is a populous, lively place. Antwerp, once the emporium of the European continent, is now conſiderably reduced.

Miles.	—— GERMANY. ——	Degrees.	Sq. Miles.
Length 600 Breadth 520	lies between	5 and 19 Eaſt long. 45 and 55 North lat.	181,631.

The empire of Germany, properly ſo called, is bounded by the German Ocean, Denmark, and the Baltic, on the North; by Poland and Hungary, including Bohemia, on the Eaſt; by Switzerland and the Alps, which divide it from Italy, on the South; and by the dominions of France and the Low Countries, on the Weſt, from which it is ſeparated by the Rhine, Moſelle, and the Maeſe. Germany is divided into nine Grand Diſtricts, of which three are in the North, three in the middle, and three in the South.

The northern circles, — *Upper Saxony, Lower Saxony, Weſtphalia.*
The circles in the middle, — *Upper Rhine, Lower Rhine, Franconia.*
The ſouthern circles, — *Auſtria, Bavaria, Swabia.*

Marquiſate of Burgaw.		Burgaw, eaſt	—	650
Territory of Briſgaw on the Rhine		Friburg and Briſac		380

The Germans went by various names, ſuch as Allemanni, Teutones; which laſt is ſaid to have been their moſt ancient deſignation: and the Germans themſelves call their country Teutchland. The chief mountains of Germany are the Alps, which divide it from Italy, and thoſe which ſeparate Saxony, Bavaria, and Moravia, from Bohemia. Berlin, which is accounted the capital of his Pruſſian majeſty's dominions, lies on the river Spree, and, beſides a royal palace, has many other ſuperb palaces; it contains fourteen Lutheran, and eleven Calviniſt churches. We can ſay little more of Dreſden, the elector of Saxony's capital, than hath been already ſaid of all fine cities, that its fortifications, palaces, public buildings, churches, and charitable foundations, and, above all, its ſuburbs, are magnificent beyond all expreſſion; that it is beautifully ſituated on both ſides the Elbe; and that it is the ſchool of Germany for ſtatuary, painting, enamelling, and carving. The city of Leipſic in Upper Saxony, is 46 miles diſtant from Dreſden, and is ſituated in a pleaſant and fertile plain on the Pleiſſe. The city of Hanover, the capital of that electorate, ſtands on the river Leine, and is a neat, thriving, and agreeable city. The biſhoprick of Oſnaburg, lies between the rivers Weſer and Ems. The chief city, Oſnaburg, has been long famous all over Europe for the manufacture known by the name of the duchy, and for the beſt Weſtphalia hams. Breſlau, the capital of Sileſia, is a fine city lying on the river Oder. Frankfort is ſituated in a healthful, fertile, and delightful country along the Maine, by which it is divided into two parts, diſtinguiſhed by the names of Frankfort and Saxenhauſen. The former of theſe, being the largeſt, is divided into twelve wards, and the latter into two. Vienna is the capital of the circle of Auſtria, and, being the reſidence of the emperor, is ſuppoſed to be the capital of Germany. It is a noble and ſtrong city, and the princes of the houſe of Auſtria have omitted nothing that could contribute to its grandeur and riches.

KINGDOM OF PRUSSIA, FORMERLY DUCAL PRUSSIA.

This country is bounded to the North by part of Samogitia; to the South, by Poland Proper and Maſovia; to the Eaſt, by part of Lithuania; and to the Weſt, by Poliſh Pruſſia and the Baltic. Its greateſt length is about 160 miles, and breadth about 112. The name of Pruſſia is probably derived from the Boruſſi, the ancient inhabitants of the country. The air, upon the whole, is wholeſome, and the ſoil fruitful. As Pruſſia, ſince the beginning of the preſent century, has become a moſt reſpectable power upon the continent of Europe, we ſhall ſtate the whole of his Pruſſian majeſty's territories, which lie ſcattered in other diviſions of Germany; Poland, Switzerland, and the northern kingdoms, with their names; all which are in the following Table:

Proteſtants.	Countries Names.	Square Miles.	Length.	Breadth.	Chief Cities.	
Poland.	Ducal Pruſſia	9,950	160	112	KONINGSBERG	54-44N la. 21-35E lo.

	Total —	51,281				

Beſides a great part of Sileſia, which the late king of Pruſſia, under various pretences, wreſted from Auſtria; availing himſelf alſo of the internal troubles in Poland, he has, by virtue of no other right than that which a powerful army confers on every tyrant, ſeized upon Thorn, with the countries on the Viſtula, and the Neiſter, and other territories contiguous to his own dominions cloſe to the walls of Dantzic.

The kingdom of Pruſſian is divided into the German and Lithuanian departments; the former of which contains 280 pariſhes, and the latter 105. Koningſberg, the capital of the whole kingdom, ſeated on the river Pregel, over which it has ſeven bridges, is about 84 miles from Dantzic. According to Dr. Buſching, the city is ſeven miles in circumference.

Miles. — KINGDOM *of* BOHEMIA. — Degrees.

Length 478 Breadth 322	lies between	48 and 52 north latitude. 12 and 19 eaſt longitude.

Bounded by Saxony and Brandenburg, on the North; by Poland and Hungary, on the Eaſt; by Auſtria and Bavaria on the South; and by the palatinate of Bavaria, on the Weſt; formerly comprehending, 1. Bohemia Proper; 2.a Sileſi; and, 3. Moravia.

Diviſions.	Chief Towns.	Miles.	Sq.M.
1. Bohemia Proper, W. moſtly ſubject to the Houſe of Auſtria.	Prague, E. lon. 14-20. N. lat. 50. Konningſgratz, E. Glatz, E. ſubject to the king of Pruſſia. Egra, W.	Length 162 Breadth 142	12060
2. Sileſia, Eaſt, moſtly ſubject to the king of Pruſſia.	Breſlaw, E. long. 17. N. lat. 51-15. Glogaw, N. Croſſen, N. Jagendorf, S. Tropaw, & Treſchen, S. both ſubj. to the houſe of Auſtria.	Length 196 Breadth 92	10250
3. Moravia, S. entirely ſubj. to the houſe of Auſtria.	Olmuntz, E. lon. 16-45. N. lat. 49-40. Brin, middle. Igla, S. W.	Length 120 Breadth 88	5124

Prague, the capital of Bohemia, is one of the fineſt and moſt magnificent cities in Europe, and famous for its noble bridge. Its circumference is ſo large, that the grand Pruſſian army, in its laſt ſiege, never could completely inveſt it. For this reaſon it is able to make a vigorous defence in caſe of a regular ſiege.

Miles. — HUNGARY. — Degrees. Sq. Miles

Length 300 } lies between { 17 and 23 Eaſt long. } 36,060
Breadth 200 } lies between { 45 and 49 North lat. }

That part of Hungary which belongs to the houſe of Auſtria (for it formerly included Tranſylvania, Sclavonia, Croatia, Morlachia, Servia, Walachia, and other countries), is bounded by Poland, on the North; by Tranſylvania, and Walachia, Eaſt; by Sclavonia, South; and by Auſtria and Moravia, Weſt.

The Kingdom of Hungary is uſually divided into the Upper and Lower Hungary.

Upper Hungary, *North of the Danube*. — Chief Towns.

Preſburg, ſituate on the Danube, E. lon. 17-30. N. lat. 48-20. Newhauſel, N. W. Leopolſtadt, N. W. Chremnits, N. W. Schemnits, in the middle. Eſperies, N. Caſchaw, N. Tokay, N. E. Zotmar, N. E. Unguar, N. E. Mongats, N. E. Waradin, Great, E. Segedin, S. E. Agria, in the middle. Peſt, on the Danube, oppoſite to Buda.

Lower Hungary, *South of the Danube*. — Chief Towns.

Buda, on the Danube, E. lon. 19-20. N. lat. 47-40. Gran, on the Danube, above Buda. Comorra, on the Danube, in the iſland of Schut. Raab, on the Danube, oppoſite to the iſland of Schut. Atlenburg, W. oppoſite to the iſland of Schut. Weiſſenburg, or Alba Regalis, ſituated E. of the lake, called the Platten Sea. Kaniſba, S. W. of the Platten ſea. Five churches, N. of the river Drave.

To which may be added Temeſwar, which had been conſidered as diſtinct from Hungary, becauſe it was formerly governed by an independent king; and it has ſeveral times been in the poſſeſſion of the Turks; but the Auſtrians gaining poſſeſſion of it, it was incorporated into the kingdom of Hungary in 1778. The province of Temeſwar, is 94 miles long, and 67 broad, containing about 3850 ſquares miles; it has been divided into four diſtricts, Cſadar, Temeſwar, Werſchez, and Lugos. Temeſwar, the principal town, is ſituated E. lon. 22-15. N. lat. 45-54. The chief rivers are the Danube, Drave, Save, Teyeſſe, Meriſh, and the Temes. The chief mountains are the Carpathian, which divide Hungary from Poland on the north. Preſburg is a fortified town, in it the Hungarian regalia were kept, but were lately removed to Vienna.

TRANSYLVANIA, SCLAVONIA, CROATIA, AND HUNGARIAN DALMATIA.

Theſe countries are thrown under one diviſion, becauſe we have no account ſufficiently exact of their extent and boundaries. The beſt account of them is as follows: Tranſylvania belongs to the houſe of Auſtria, and is bounded on the North by the Carpathian mountains, which divide it from Poland; on the Eaſt by Moldavia, and Walachia; on the South by Walachia; and on the Weſt by Upper and Lower Hungary. It lies between 22 and 25 degrees of eaſt longitude, and 45 and 48 of north latitude. Its length is extended about 180, and its breadth 120 miles; and contains nearly 14,400 ſquare miles, but it is ſurrounded on all ſides by high mountains. The chief city is Hermanſtadt, and its interior government ſtill partakes greatly of the ancient feudal ſyſtem, being compoſed of many independent ſtates and princes. They owe not much more than a nominal ſubjection to the Auſtrians, who leave them in poſſeſſion of many of their privileges.

Sclavonia lies between the 16th and 23d degrees of eaſt longitude, and the 45th and 47th of north latitude. It is thought to be about 200 miles in length, and 60 in breadth, and contains about 10,000 ſquare miles. It is bounded by the Drave on the North, by the Danube on the Eaſt, by the Save on the South, and by Kiria in Auſtria on the Weſt. In 1746, Sclavonia was united to Hungary, and the ſtates ſend repreſentatives to the diet of Hungary.

Croatia lies between the 15th and 17th degrees of eaſt longitude, and the 45th and 47th of north latitude. It is 80 miles in length, and 70 in breadth. All the ſovereignty exerciſed over them by the Auſtrians ſeems to conſiſt in the military arrangements for bringing them occaſionally into the field.

Hungarian Dalmatia lies in the upper part of the Adriatic ſea, and conſiſts of five diſtricts, in which the moſt remarkable place is the following; Segna, which is a royal free town, fortified both by nature and art, and is ſituated near the ſea, in a bleak, mountainous, and barren ſoil.

POLAND, including LITHUANIA.

Miles. Degrees.

Length 700 } lies between { 16 and 34 eaſt longitude.
Breadth 680 } lies between { 46 and 57 north latitude.

Before the late extraordinary partition of this country, the kingdom of Poland, with the great duchy of Lithuania annexed, (anciently called Sarmacia) was bounded on the North by Livonia, Muſcovy, and the Baltic ſea; on the Eaſt by Muſcovy; on the South by Hungary, Turkey, and Little Tartary; on the Weſt by Germany; and had the form of its government been as perfect as its ſituation was compact, it might have been one of the moſt powerful kingdoms in the univerſe. Its grand diviſions were as follow,

	Poland.	Square Miles.	Length.	Breadth.	Chief Cities.	
Proteſtants.	Courland, ſubject to Ruſſia.	4,414	174	80	Mittaw	
Papiſts.	Lithuania,	64,800	333	310	Wilna	Great part of this diſtrict is now poſſeſſed by Ruſſia.

	Volhinia,	25,000	305	150	Lucko	
	Great Poland,	19,200	208	180	Gneſna	
	Red Ruſſia,	25,200	232	185	Lemburg	Now chiefly ſubject to Auſtria.
	Little Poland,	18,000	230	130	Cracow	
	Poleſia,	14,000	186	97	Breſſici	
	Maſovia,	8,400	152	90	Warsaw	E. lon. 21-5. N. lat. 52-15.
	Samogitia,	8,000	155	98	Raſiem	
	Pruſſia Royal, or Poliſh Pruſſia,	6,400	118	104	Elbing	Now ſubject to Pruſſia
	Polachia,	4,000	133	42	Bielh	
	Total —	226,414				

Dantzic, Thorn, and Elbing, in Pruſſia Royal, are ſtyled free cities, and were under the protection of Poland; the two laſt were ſeized by the late king of Pruſſia, and moſt of the privileges of the firſt.

Poland is in general a level country, and the ſoil is fertile in corn, alſo the paſtures of Poland, eſpecially in Podolia, are rich beyond expreſſion. The chief rivers of Poland are, the Viſtula or Weyſel, the Neiſter, Neiper or Boriſthenes, the Bog, and the Dwina. Dantzic is the capital of Poliſh Pruſſia. It is ſituated on the Viſtula, near five miles from the Baltic, and is a large, beautiful, populous city; its houſes generally are five ſtories high; and many of its ſtreets are planted with cheſnut-trees. It has a fine harbour, and is a moſt eminent commercial city. It is a republic, claiming a ſmall adjacent territory about forty miles round it.

Miles. — SWITZERLAND. — Degrees.

Length 260 } lies between { 6 and 11 eaſt longitude.
Breadth 100 } lies between { 45 and 48 north latitude.

It it bounded by Alſace and Swabia in Germany, on the North; by the lake of Conſtance, Tirol, and Trent, on the Eaſt; by Italy, on the South; and by France, on the Weſt. Switzerland is divided into thirteen cantons, which ſtand in point of precedency as follows: 1. Zurich; 2. Berne; 3. Lucerne; 4. Uri; 5. Schweitz; 6. Underwalden; 7. Zug; 8. Glaris; 9. Baſil; 10. Fribourg; 11. Soleure; 12. Schaffhauſen; 13. Appenzel.

The beſt account we have of the dimenſions and principal towns of each canton, is as follows:

					Mulhauſen, in Alſace, is alſo united to them.
	Total	12,884			

This is a mountainous country, lying upon the Alps, (which form an amphitheatre of more than 100 miles) the hills are covered with ſnow ſometimes all the year long. On one ſide of thoſe mountains the inhabitants are often reaping, while they are ſowing on another. The vallies are warm and fruitful, and well cultivated, and nothing can be more delightful than the ſummer months in this charming country. The chief rivers are the Rhine, which riſes in the chain of mountains bordering on St. Gothard, the Aar, the Reuſs, the Teſin, the Oglio, and the Rhone. The moſt conſiderable city is Bern, ſtanding on the river Aar. All the other cities in Switzerland are excellently well provided with arſenals, bridges, and public edifices. Baſil is accounted by ſome the capital of all Switzerland. It is ſituated in a fertile and delightful country, on the banks of the Rhine, and the confines of Alſace and the empire. The ſituation of Baſil is pleaſing; the Rhine divides it into the upper and lower town, and it is conſidered as one of the keys of Switzerland. Baden is ſamous for its antiquity and baths. Zurich is far leſs conſiderable than Bern. The city of Geneva, which is an aſſociate of Switzerland, and is under the protection of the Helvetic body, but within itſelf is an independent ſtate, and republic. The city is well built, and well fortified, ſituated upon the afflux of the Rhone, from the large fine lake of Geneva. Neufchater, ſince the year 1707, hath been under the dominion of the king of Pruſſia, but the inhabitants are free to ſerve any prince whatever, and by no means bound to take an active part in his wars.

Miles. —— SPAIN. —— Degrees.

Length 700 } lies between { 10 and 3 eaſt longitude.
Breadth 500 } lies between { 36 and 44 north latitude.

It is bounded on the Weſt by Portugal and the Atlantic Ocean; by the Mediterranean, on the Eaſt; by the Bay of Biſcay and the Pyrenean mountains, which ſeparate it from France, on the North; and by the ſtrait of the ſea of Gibraltar, on the South. It is now divided into fourteen diſtricts, beſides iſlands of the Mediterranean.

The town and fortreſs of Gibraltar, ſubject to Great Britain.

Spain formerly included Portugal, and was known to the ancients by the name of Iberia, and Heſperia, as well as Hiſpania. It was, about the time of the Punic wars, divided into Citerior and Ulterior: the Citerior contained the provinces lying north of the river Ebro: and the Ulterior, which was the largeſt part, comprehended all that lay beyond that river. Innumerable are the changes that it afterwards underwent; but there is no country of whoſe ancient hiſtory, at leaſt the interior part of it, we know leſs than that of Spain.

The mountains in Spain are numerous, the chief, and the higheſt, are the Pyrenees, near 200 miles in length, which extend from the Bay of Biſcay to the Mediterranean, and divide Spain from France. The Cantabrian mountains (as they are called) are a kind of continuation of the Pyrenees, and reach to the Atlantic Ocean, ſouth of Cape Finiſterre. No Engliſhman ought to be unacquainted with Mount Calpe, now called the hill of Gibraltar, and in former times, one of the pillars of Hercules; the other, Mount Abyla, lying oppoſite to it in Africa. The mountain Montſerrat is one of the moſt ſingular in the world, for ſituation, ſhape, and compoſition. It ſtands in a vaſt plain, about thirty miles from Barcelona, and nearly in the centre of the principality of Catalonia. It is ſo broken and divided, and ſo crowned with an infinite number of ſpiring cones, or pine heads, that it has the appearance, at a diſtant view, to be the work of man, but upon a nearer approach, to be evidently the production of the God of nature; each cone appearing of itſelf a mountain; and the whole compoſing an enormous maſs about 14 miles in circumference; and the Spaniards compute it to be two leagues in height.

The chief rivers are the Duero, formerly Durius, which falls into the Atlantic Ocean below Oporto in Portugal; the Tajo or Tagus, which falls into the Atlantic Ocean below Liſbon; the Guadiana falls into the ſame ocean near Cape Finiſterre; as does the Guadalquiver, now Turio, at St. Lucar: and the Ebro, the ancient Iberus, falls into the Mediterranean ſea below Tortoſa. The river Tinto, the qualities of which are very extraordinary, riſes in Sierra Morena, and empties itſelf into the Mediterranean near Huelva, having the name of Tinto given it from the tinge of its waters, which are as yellow as the topaz, hardening the ſand, and petrifying it in a moſt ſurpriſing manner. The chief bays are thoſe of Biſcay, Ferrol, Corunna, (commonly called the Groyne,) Vigo, Cadiz, Gibraltar, Carthagena, Alicant, Altea, Valencia, Roſes, Majorca in that iſland, and the harbour of Port-Mahon in the iſland of Minorca. The ſtrait of Gibraltar divides Europe from Africa. In blowing up the rock of Gibraltar, many pieces of bones and teeth have been found incorporated with the ſtone, ſome of which have been brought to England.

Madrid, though unfortified, is the capital of Spain; it is ſurrounded with very lofty mountains, whoſe ſummits are frequently covered with ſnow. It is well paved and lighted, and ſome of the ſtreets are ſpacious and handſome. Cadiz is the great emporium of Spaniſh commerce. It ſtands on an iſland ſeparated from the continent of Andaluſia, without the ſtraits of Gibraltar, by a very narrow arm of the ſea, over which a fortified bridge is thrown, and joins it to the main land. Seville, the Julia of the Romans, is next to Madrid, the largeſt city in Spain, but is greatly decayed, both in riches and population. The ſhape is circular, and the walls ſeem of Mooriſh conſtruction; its circumference is five miles and a half. The ſuburb of Triana is as large as many towns, and remarkable for its gloomy Gothic caſtle. Barcelona, formerly Barcino, ſaid to be founded by Hamilcar Barcas, is a large circular trading city, ſituated on the Mediterranean facing Minorca, and is ſaid to be the handſomeſt place in Spain; the houſes are lofty and plain, and the ſtreets well lighted, and paved. The citadel is ſtrong, and the place and inhabitants famous for the ſiege they ſuſtained in 1714 againſt a formidable army, when deſerted both by Engand and the emperor, for whom they had taken up arms. Valencia is a large and almoſt circular city, with lofty walls. The ſtreets are crooked and narrow, and not paved, the houſes alſo are ill built. Carthagena is a large city, but has very few good ſtreets, and fewer remarkable buildings. The port however is very complete. Granada ſtands on two hills, and the ancient palace of the Alhambra, crowns the double ſummit between two rivers, the Douro, and the Xenil. Bilboa is ſituated on the banks of the river Ybaizabel, and is about two leagues from the ſea. The houſes are ſolid and lofty, and the ſtreets well paved and level; and the water is ſo conveyed into the ſtreets, that they may be waſhed at pleaſure. Malaga is an ancient city, large and populous, and of a circular form, ſurrounded with a double wall, ſtrengthened by ſtately towers, and has nine gates. A Mooriſh caſtle on the point of a rock commands every part of it.

The city of Salamanca is of a circular form, but on three hills and two vallies, and on every ſide ſurrounded with proſpects of fine houſes, noble ſeats, gardens, orchards, fields, and diſtant villages; and is ancient, large, rich, and populous. Toledo is one of the moſt ancient cities in Spain, and during ſeveral centuries it held the rank of its metropolis. It is now exceedingly ill-built, poor and mean, and the ſtreets very ſteep. Burgos was the ancient capital of the kingdom of Caſtile, but now in obſcurity. Gibraltar, once a celebrated town and fortreſs of Andaluſia, is at preſent in poſſeſſion of Great Britain. It is a commodious port, and formed naturally for commanding the paſſage of the Straits, or, in other words, the entrance into the Mediterranean and Levant ſeas. But the road is neither ſafe againſt an enemy nor ſtorms: the bay is about twenty leagues in circumference. The Straits are 24 miles long, and 15 broad; through which ſets a current from the Atlantic ocean into the Mediterranean, and for the ſtemming of it a briſk gale is required. There is not a town in Spain but what has a large ſquare for the purpoſe of exhibiting bull-fights: and it is ſaid that even the pooreſt inhabitants of the ſmalleſt villages will often club together in order to procure a cow or an ox, and fight them, riding upon aſſes for want of horſes. The chief iſlands belonging to Spain in Europe, are thoſe of Majorca and Yvica. Minorca alſo is now become a Spaniſh iſland.

Miles. —— PORTUGAL. —— Degrees.

Length 300 } lies between { 37 and 42 North lat.
Breadth 100 } lies between { 7 and 10 Weſt lon.

It is bounded by Spain on the North and Eaſt, and on the South and Weſt by the Atlantic Ocean, being the moſt Weſterly kingdom on the continent of Europe. This kingdom was, in the time of the Romans, called Luſitania. The etymology of the modern name is uncertain. It moſt probably is derived from ſome noted harbour or port, to which the Galls (for ſo ſtrangers are called in the Celtic) reſorted. By the form of the country, it is naturally divided into three parts, the north, middle, and ſouth Provinces.

	Provinces.	Chief Towns	Sq M.
The North Diviſion contains	Entre Minho	Braga	6814
	Duro and	Oporto and Viana	
	Tralos Montes	Miranda and Villa Real	
The Middle Diviſion contains	Beira	Coimbra	12640
		Guarda Caſtel Rodrigo	
		LISBON { 38-42N.la. 8 53W.lo	
	Eſtramadura	St. Ubes, and Leira.	
The South Diviſion contains	Entre Tago	Ebora, or Evora	8397
	Guardiana	Portalegre, Elvas, Beja	
	Alentejo	Legos	
	Algarva	Faro, Tavora, & Silves	

The face of Portugal is mountainous, or rather rocky, for their mountains are generally barren: the chief are thoſe which divide Algarva from Alentejo; thoſe of Tralos Montes, and the rock of Liſbon, at the mouth of the Tajo. Though every brook in Portugal is reckoned a river, yet the chief Portugueſe rivers are mentioned in Spain, all of them falling into the Atlantic ocean. The Tagus, or Tajo, was celebrated for its golden ſand. The dormontories or capes of Portugal are Cape Mondego, near the mouth of the river Mondego; Cape Roca, at the north entrance of the river Tajo; Cape Eſpithel, at the ſouth entrance of the river Tajo; and Cape St. Vincent, on the ſouth weſt point of Algarva. The bays are thoſe of Cadoan, or St. Ubes, ſouth of Liſbon, and Lagos bay in Algarva. Liſbon is the capital of Portugal. Great part of it was ruined by an earthquake, which alſo ſet the remainder on fire, upon All-Saints day, 1755. Its ſituation (riſing from the Tagus in the form of a creſcent) renders its appearance at once delightful and ſuperb, and it is deſervedly accounted the greateſt port in Europe, next to London and Amſterpam. The harbour is ſpacious and ſecure, and the city itſelf is guarded from any ſudden attack towards the ſea by forts. All that part of the city that was demoliſhed by the earthquake, is planned out in the moſt regular and commodious form. The ſecond city in this kingdom is Oporto.

Miles. —— ITALY. —— Degrees.

Length 600 } lies between { 38 and 47 north latitude.
Breadth 400 } { 7 and 19 eaſt longitude.

Nature has fixed the boundaries of Italy; for towards the Eaſt it is bounded by the Gulf of Venice, or Adriatic ſea; on the South and Weſt by the Mediterranean ſea; and on the North, by the lofty mountains of the Alps, which divide it from France and Switzerland.

The whole of the Italian dominions, comprehending Corſica, Sardinia, the Venetian and other iſlands, are divided and exhibited in the following table.

Italy.	Countries Names.	Square Miles.	Length.	Breadth.	Chief Cities.

The Alps and Appennines are the chief mountains of Italy. The famous volcano of Mount Veſuvius lies in the neighbourhood of Naples. The rivers of Italy are the Po, the Var, the Adige, the Trebia, the Arno, and the Tiber, which runs through the city of Rome. The famous Rubicon forms the ſouthern boundary between Italy and the ancient Ciſalpine Gaul. The lakes of Italy are, the Maggiore, Lugano, Como, Iſco, and Garda in the North; the Perugia or Thraſimene, Bracciana, Terni, and Celano, in the middle. Rome is the chief city in the Pope's Territories, and was formerly the capital of the world. It is ſituate on the River Tiber, in lat. 41° 54′ N. and long. 12° 29′ E. being 140 miles N. W. of Naples, 140 S. of Florence, and 16 miles N. E. of the Tuſcan Sea. The walls ſurrounding the city make a circumference of about 12 miles, but not a third part of the ground is built upon. It is, however, a magnificent city, the ſtreets, in general, being ſpacious and adorned with a vaſt number of elegant buildings, ſuch as churches, palaces, convents, triumphal arches, pillars, obeliſks, ſtatues, &c. Alſo the various fountains are no ſmall addition to its beauty. Florence the capital of Tuſcany, ſituated on the River Arno, is one of the moſt elegant towns in Italy; of a round figure, and about 61 miles in circumference. It lies 58 miles S. of Bologna, 140. N. of Rome, and 45 E. of Leghorn and the Tuſcan Sea. Its lat. is 43° 46½′ N. and long. 11° 2′ E. Naples, the capital of the kingdom of Naples, is an elegant built town, ſtanding on an eminence which riſes gradually from the Sea. On the eaſt is a large plain, beyond which is Mount Veſuvius. It is about 7 miles in circumference, and 140 S. E. of Rome, in lat. 40° 50′ N. and long. 14° 13′ E.

Milan, the capital of the Milaneſe, is an elegant built town, having many ſpacious ſtreets and ſquares. It is ſituated on the Rivers Olana and Lombro, 250 miles N. W. of Rome, and 100 miles N. E. of Turin; lat. 45° 28′ N. and long. 6° 10′ E. Turin the capital of Piedmont, is a neat city, adorned with many lofty and magnificent buildings, and a beautiful royal palace. It is of a ſquare figure, about 3 miles in circumference, ſituated at the confluence of the river Po, and Doria being 100 miles S. W. of Milan, and 100 N. W. of Genoa, in lat. 45° 5′ N. and long. 7° 40′ E. Genoa, the capital of the republic of Genoa, ſtands near the ſea and has an excellent harbour, the city is about 6 miles in circumference, in lat. 44° 25′ N. and long. 8° 36′ E. Venice, the capital of the Duchy of Venice, is ſituated 220 miles N. of Rome, 150 E. of Milan, and 250 E. of Turin, ſtanding upon a vaſt number of little iſlands in the ſea. It is ſo happily ſituated that no army can approach it by land, nor any hoſtile fleet by ſea. The circumference of the city is about 6 miles. To any part of the city one may go by water, and there are no leſs than 450 bridges over the canals. It is in lat. 45. 26. N. and long. 12° 4½′ E. The reſt of the towns in Italy are in general agreeably built; and the country itſelf is ſo remarkably pleaſant and fertile, that it has been deemed the garden of the world.

tal of this great empire, is ſituated on the European ſide of the Boſphorus; and is at this day one of the fineſt cities in the world, by its ſituation and its port. The proſpect from it is noble. The moſt regular part is the Beſeſtin, incloſed with walls and gates, where the merchants have their ſhops excellently ranged. The city is built in a triangular form, with the Ottoman palace ſtanding on a point of one of the angles, from whence there is a proſpect of the delightful coaſt of the Leſſer Aſia, which is not to be equalled.

ISLANDS BELONGING TO TURKEY IN EUROPE, BEING PART OF ANCIENT GREECE.

Negropont, the ancient Euboea, ſtretches from the ſouth-eaſt to the north-weſt, and on the eaſtern coaſt of Achaia, or Levadia. It is 90 miles long, and 25 broad, and contains about 1300 ſquare miles. The iſland is very fertile, and all kinds of proviſions are extremely cheap. The chief towns in the iſland are, Negropont called by the Greeks Egripos, ſituated on the ſouth-weſt coaſt of the iſland, on the narroweſt part of the ſtrait; and Caſtel Roſſo, the ancient Caryſtus. Lemnos, or Stalimene, lies on the north part of the Egean ſea or Archipelago, and is almoſt a ſquare of 25 miles in length and breadth. Tenedos lies oppoſite to old Troy, and is mentioned by Virgil as the place to which the Greeks retired, and left the Trojans in a fatal ſecurity. Scyros is about 60 miles in circumference, and contains many remains of antiquity. Leſbos, or Mytelene, is about 60 miles long, and is famous for the number of philoſophers and poets it produced. Scio, or Chios, lies about 80 miles weſt of Smyrna, and is about 100 miles in circumference. It is inhabited by Greeks, Turks, and Latins. Samos lies oppoſite to Epheſus, on the coaſt of the Leſſer Aſia, about ſeven miles from the continent. It is 30 miles long, and 15 broad. This iſland gave birth to Pythagoras. To the ſouth of Samos lies Patmos, about 20 miles in circumference, but ſo barren, and dreary, that it may be called a rock rather than an iſland. It has, however, a convenient haven; and the few Greek monks who are upon the iſland ſhew a cave where St. John is ſuppoſed to have written the Apocalypſe. The Cyclades iſlands lie like a circle round Delos, the chief of them, which is ſouth of the iſlands of Mycone and Tirſe, and almoſt midway between the continents of Aſia and Europe. Delos is about ſix miles in circumference, and is almoſt deſtitute of inhabitants. Paros lies between the iſlands of Luxia and Melos. Like all the other Greek iſlands, it contains ſtriking and magnificent ruins of antiquity. Cerigo, or Cytherea, lies ſouth-eaſt of the Morea, and is about 50 miles in circumference, but is rocky and mountainous. Santoria is one of the moſt ſouthern iſlands in the Archipelago, and was formerly called Caliſta, and afterwards Thera. Near this iſland another aroſe of the ſame name, from the bottom of the ſea, in 1707. It is about 200 feet above the ſea; and at the time of its firſt emerging, it was about a mile broad, and five miles in circumference, but it has ſince increaſed. Several other iſlands of the Archipelago appear to have had the like original, but the ſea in their neighbourhood is ſo deep as not to be fathomed. The famous iſland of Rhodes is ſituated in the 28th degree of eaſt longitude, and 36 degrees 10 minutes north latitude, about 20 miles ſouth-weſt of the continent of Leſſer Aſia, being about 60 miles long, and 25 broad. This is a healthful and pleaſant iſland. The chief town, of the ſame name, ſtands on the ſide of a hill fronting the ſea, and is three miles in circumference. Candia, the ancient Crete, is ſtill renowned for its hundred cities. It lies between 35 and 36 degrees of north latitude, being 200 miles long, and 60 broad, almoſt equally diſtant from Europe, Aſia, and Africa, and contains 3220 ſquare miles. The famous Mount Ida ſtands in the middle of the iſland, and is no better than a barren rock; and Lethe, the river of oblivion, is a torpid ſtream.

Cyprus lies in the Levant ſea, about 20 miles diſtant from the coaſts of Syria and Paleſtine. It is 150 miles long, and 70 broad, and lies at almoſt an equal diſtance from Europe and Africa. The iſlands in the Ionian ſea are, Sapienza, Stivali, Zante, Cephalonia, Santamaura, Corfu, Fannu, and others of ſmaller note, particularly Iſola del Compare, the birth-place and kingdom of Ulyſſes. Zante has a populous capital of the ſame name, and is a place of conſiderable trade, the citadel is erected on the top of a large hill, ſtrong by nature, but now little better than a heap of ruins.

ASIA.

As Aſia exceeds Europe and Africa in the extent of its territories, it is alſo ſuperior to them in the ſerenity of its air, the fertility of its ſoil, the deliciouſneſs of its fruits, the fragrancy and balſamic qualities of its plants, ſpices, and gums; the ſalubrity of its drugs; the quantity, variety, beauty, and value of its gems, the richneſs of its metals, and the fineneſs of its ſilks and cottons. The continent of Aſia is ſituated between 25 and 180 degrees of eaſt longitude, and between the equator and 80 degrees of north latitude. It is about 4740 miles in length, from the Dardanelles on the weſt, to the eaſtern ſhore of Tartary; and about 4380 miles in breadth, from the moſt ſouthern part of Malacca, to the moſt northern cape of Nova Zembla. It is bounded by the Frozen ocean on the north; on the Weſt it is ſeparated from Africa by the Red Sea, and from Europe by the Levant or Mediterranean, the Archipelago, the Helleſpont, the ſea of Marmora, the Boſphorus, the Black Sea, the river Don, and a line drawn from it to the river Tobol, and from thence to the river Oby, which falls into the Frozen Ocean. On the Eaſt, it is bounded by the Pacific Ocean, or the South Sea, which ſeparates it from America; and on the South by the Indian Ocean; ſo that it is almoſt ſurrounded by the ſea. The principal regions which divide this country are as follow:

	Nations.	Length	Breadt.	Square Miles.	Chief Cities.	Diſt. and bearing fm. Lond.	Diff. of time from London.	Religions
Tartary.	Ruſſian	The bounds of theſe parts are unlimited, each power puſhing on his conqueſts as far as he can.		3,050,000	Tobolſk	2160 N.E.	4 10 bef	Ch & Pag

Eaſt of the Levant Sea.	Syria, with Paleſtine, or the Holy Land.	Aleppo, Antioch, Damaſcus, Tyre, Sidon, Tripoli, Scanderoon, & Jeruſalem

In Turkey and Aſia are the following mountains; famous in ſacred as well as profane writings.—Olympus; Taurus and Antitaurus; Caucaſus and Ararat; Lebanon; and Hermon: and the rivers of like note are the Euphrates; Tigris; Orontes; Meander; Sarabat; Kara; and Jordan.

Balbec is ſituated on a riſing plain, between Tripoli in Syria, and Damaſcus, at the foot of mount Libanus, and is the Heliopolis of Cælo Syria. *Palmyra*, or, as it was called by the ancients, Tadmor in the Deſert, is ſituated in the wilds of Arabia Petræa, about 33 deg. N. lat. and 200 miles to the ſouth-eaſt of Aleppo. It is approached through a narrow plain, lined with the remains or ruins of the moſt elegant ſtructures found in the world.

Mecca and *Medina* are much revered by the Mahometans, but their buildings are mean, and even the temple of Mecca, in point of architecture, makes but a ſorry appearance, though erected on a ſpot where the great prophet is ſaid to have been born. The ſame may be ſaid of the moſque at Medina, where that impoſtor was buried. The neighbourhood of Smyrna (now called Iſmir), contains many valuable antiquities. The ſame may be ſaid of Aleppo, and a number of other places celebrated in antiquity, and now known only by geographical obſervations. The ſeat of Old Troy cannot be diſtinguiſhed by the ſmalleſt veſtige, and is known only by its being oppoſite to the iſle of Tenedos, and the name of a brook which the poets magnified into a wonderful river. Scanderoon ſtands upon the ſite of Old Alexandria, but it is now almoſt depopulated. Aleppo preſerves a reſpectable rank among the cities of the Aſiatic Turkey. It is ſtill the capital of Syria, and is ſuperior in its buildings and conveniencies to moſt of the Turkiſh cities. Aleppo and its ſuburbs are ſeven miles in compaſs, ſtanding on eight ſmall hills, on the higheſt of which the citadel or caſtle is erected, but of no great ſtrength.

Bagdad, built upon the Tigris, not far it is ſuppoſed from the ſite of ancient Babylon, is the capital of the ancient Chaldea, and was the metropolis of the Caliphate, under the Saracens, in the twelfth century. This city retains but few marks of its ancient grandeur. It is in the form of an irregular ſquare, and rudely fortified, but the conveniency of its ſituation renders it one of the ſeats of the Turkiſh government, and it has ſtill a conſiderable trade, being annually viſited by the Smyrna, Aleppo, and weſtern caravans. Ancient Aſſyria is now called the Turkiſh Curdiſtan, though part of it is ſubject to the Perſians. The capital is Curdiſtan, the ancient Nineveh being now a heap of ruins. Georgia, or Gurgiſtan, now no longer ſubject to the Turks, is chiefly peopled by Chriſtians. Their capital Teflis, is a handſome city, and makes a fine appearance. It is ſituated at the foot of a mountain, by the ſide of the river Kur, and is ſurrounded by ſtrong walls, except on the ſide of the river. It has a large fortreſs on the declivity of the mountain. The ancient cities of Damaſcus, Tyre, and Sidon, ſtill retain part of their former trade. Damaſcus is called Sham, and the approach to it by Sidon, now Said, which likewiſe lies within the ancient Phœnicia, has ſtill ſome trade, and a tolerable harbour. Tyre, now called Sur, about 20 miles diſtant from Sidon, is now inhabited by few miſerable fiſhermen, who live in the ruins of its ancient grandeur. The circumference of the place is not more than a mile and a half, and ſome of the ruins of ancient Tyre are ſtill viſible. Natolia, or Aſia Minor, comprehending the ancient provinces of Lydia, Pamphylia, Piſidia, Lycaonia, Cilicia, Cappadocia, and Pontus, or Amaſia; all of them territories celebrated in the Greek and Roman hiſtory, are now, through the Turkiſh indolence and tyranny, either forſaken, or a theatre of ruins.

TARTARY IN ASIA.

Miles.		Degrees.
Length 4000	lies between	50 and 150 eaſt longitude.
Breadth 2400		30 and 72 north latitude.

It would be deceiving the reader to deſire him to depend upon the accounts given us by geographers, of the extent, limit, and ſituation of theſe vaſt regions. Even the empreſs of Ruſſia and her miniſtry are ignorant of her preciſe limits with the Chineſe, and the Perſians, and other nations. Tartary, taken in its fulleſt extent, is bounded by the Frozen Ocean on the North, by the Pacific Ocean on the Eaſt, by China, India, Perſia, and the Caſpian Sea, on the South; and by Muſcovy, on the Weſt.

Grand diviſions.	Subdiviſions.	Chief towns.	Sq. M.

Middle diviſion	Siberia	Tobolſk	
	Kalmuc Tartary	Bokharia	850,000
	Uſbeck Tartary	Samarcand	339,840

Kamtſchatka is a great peninſula, which extends from North to South about ſeven degrees thirty minutes. It is divided into four diſtricts, Bolchereſk, Tigilſkaia Krepoſt, Verchnei or Upper Kamtſchatkoi Oſtrog, and Neſhnei or Lower Kamtſchatkoi Oſtrog. The principal mountains are Caucaſus in Circaſſia, and the mountains of Taurus and Ararat, ſo contiguous to it, that they appear like a continuation of the ſame mountains, which croſſes all Aſia from Mongalia to the Indies; and the mountains of Stolpt, in the North. The Seas are the Frozen Ocean, the Pacific Ocean, and the Caſpian Sea. The principal rivers are, the Wolga, which runs a courſe of two thouſand miles; the Obey, which divides Aſia from Europe; the Tabol, Irtis, Geneſa or Jenſka; the Burrumpooter; the Lena, and the Argum, which divide the Ruſſian and the Chineſe empire. We know little of the cities and towns but the names; and that they are in general no better than fixed hordes. They may be ſaid to be places of abode rather than towns or cities, for we do not find that they are under any regular government. Tobolſk and Aſtrachan are ranked as conſiderable cities.

THE EMPIRE OF CHINA.

Miles.		Degrees.	Sq. Miles.
Length 1450	lies between	20 and 42 north lat.	1,105,000
Breadth 1260		98 and 123 eaſt lon.	

CHINESE TARTARY. —— Sq. M. 644,000.

It is bounded by Tartary and an amazing ſtone wall on the North; by the Pacific ocean which divides it from North-America, on the Eaſt; by the Chineſian ſea, South; and by Tonquin, and the Tartarian countries and mountains of Thibet and Ruſſia, on the Weſt. The great diviſion of this empire, according to the authors of the Univerſal Hiſtory, is into fifteen provinces (excluſive of that of Lyau-tong, which is ſituated without the Great Wall, though under the ſame dominion); each of which might, for their largeneſs, fertility, populouſneſs, and opulence, paſs for ſo many diſtinct kingdoms. China, excepting to the north, is a plain country, and contains no remarkable mountains. The chief rivers are the Yamour and the Argum, which are the boundary between the Ruſſian and Chineſe Tartary; the Crocceus, or Whamboo, or the Yellow River; the Kiam, or the Blue River, and the Tay. Common water in China is very indifferent, and is in ſome places boiled to make it fit for uſe. The empire is ſaid to contain 4400 walled cities; the chief of which are Peking, Nanking, and Canton. Peking, the capital of the whole empire of China, and the ordinary reſidence of the emperors, is ſituated in a very fertile plain, 20 leagues diſtant from the Great Wall. It is an oblong ſquare, and is divided into two cities: that which contains the emperor's palace, is the Tartar city. The invention of gunpowder is juſtly claimed by the Chineſe, who made uſe of it againſt Zinzis Khan and Tamerlane.

INDIA IN GENERAL.

This vaſt country is ſituated between the 66th and 109th degrees of Eaſt longitude, and between 1 and 40 of North latitude. It is bounded, on the North, by the countries of Uſbec Tartary and Thibet; on the South, by the Indian Ocean; on the Eaſt, by China and the Chineſe ſea; and on the Weſt, by Perſia and the Indian ſea. India at large is divided into three parts; firſt, the Peninſula of India beyond the Ganges, called the Farther Peninſula; ſecondly, the main land, or the Mogul's empire; thirdly, the Peninſula within or on this ſide the Ganges; all of them vaſt, populous, and extended empires.

THE PENINSULA OF INDIA BEYOND THE GANGES, CALLED THE FARTHER PENINSULA.

Miles.		Degrees.
Length 2000	lies between	1 and 30 north lat.
Breadth 1000		92 and 109 eaſt long.

This Peninſula is bounded by Thibet and China, on the north; by China and the Chineſe ſea, on the Eaſt; by the ſame ſea and the ſtraits of Malacca, on the South: and by the bay of Bengal and the Hither India, on the Weſt. The ſpace between Bengal and China, is now called the province of Mecklus, and other diſtricts ſubject to the king of Ava or Burmah.

Gr. diviſi.	Subdiviſi.	Chief towns.	Sq. M.
On the north-weſt.	Acham	Chamdara	180,000

	Cambodia	Cambodia	60,200
	Chiampa	Padram	

The name of India is taken from the River Indus, which of all others was the beſt known to the Perſians. There are mountains from North to South almoſt the whole length of the country; but the lands near the ſea are low, and annually overflowed in the rainy ſeaſon. The chief rivers are Senpoo or Burrumpooter, Domea, Mecon, Menan, and Ava, or the great river *Nou Kian*.

In this peninſula are many kingdoms, but they are little known. The few accounts that have been given of them are not to be depended on, and of courſe they are not worth enumerating here.

INDIA *within the* Ganges, *or the Empire of the* Great Mogul.

Situation *and* Extent, *including the Peninſula weſt of the* Ganges.

Miles.		Degrees.
Length 2000	lies between	7 and 40 north latitude.
Breadth 1500		66 and 92 eaſt longitude.

This empire is bounded by Uſbec Tartary, and Thibet on the North; by Thibet and the Bay of Bengal, on the Eaſt; by the Indian Ocean, on the South; by the ſame and Perſia, on the Weſt. The main land being the Mogul empire, or Indoſtan properly ſo called.

The Britiſh nation poſſeſs in full ſovereignty, the whole ſoubah of Bengal, and the greateſt part of Bahar. In Oriſſa or Orixa, only the diſtricts of Midnapour. The whole poſſeſſions contain about 150,000 ſquare miles. With their allies and tributaries, they now occupy the whole navigable courſe of the Ganges from its entry on the plains to the ſea, which by its winding courſe is more than 1350 miles. The moſt remarkable mountains are thoſe of Caucaſus and Naugracut, which divide India from Perſia, Uſbec Tartary, and Thibet; and are inhabited by Matattas, Afghans, or Patans, and other people more warlike than the Gentoos. As to the mountains of Balegant which run almoſt the whole length of India, from north to ſouth, they are ſo high as to ſtop the weſtern monſoon; the rains beginning ſooner on the Malabar, than they do on the Coromandel coaſt. The chief rivers are the Indus called by the natives Sinda and Sindeh, and the Ganges, both of them known to the ancients. Beſides thoſe rivers, many others water this country.

The ſeas, bays, and capes, are the Indian ocean; the bay of Bengal; the gulf of Cambaya: the ſtraits of Ramanakoel; Cape Comorin and Diu. The province of Adgra is the largeſt in all Indoſtan, containing 40 large towns and 340 villages. The city of Delhi, which is the capital of that province, is likewiſe the capital of Indoſtan. It is a fine city, and containing the imperial palace, which is adorned with the uſual magnificence of the Eaſt. Its ſtables formerly contained 12,000 horſes, brought from Arabia, Perſia, and Tartary; and 500 elephants. When the forage is burnt up by the heats of the ſeaſon, as is often the caſe, theſe horſes are ſaid to be fed in the morning with bread, butter, and ſugar, and in the evening with rice-milk properly prepared. Tarta, the capital of Sindia, is alſo a large city; the province of Moultan is not very fruitful, but it yields excellent iron and canes. The province of Caſſimere, is ſurrounded with mountains, and is difficult of acceſs, but when entered, it appears to be the paradiſe of the Indies. It is ſaid to contain 100,000 villages.

The province and city of Lahor formerly made a great figure in the Indian hiſtory, and is ſtill one of the largeſt and fineſt provinces in the Indies. Its capital was once about nine miles long, but is now much decayed: the provinces of Ayud, Varad, Bekar, and Hallabas, are inhabited by a hardy race of men, who ſeem never to have been conquered. Bengal, is eſteemed the ſtorehouſe of the Eaſt Indies. Its fertility exceeds that of Egypt, after being overflowed by the Nile. The country is interſected by canals cut out of the Ganges, for the benefit of commerce; and extends near 100 leagues on both ſides the Ganges, full of cities, towns, caſtles, and villages. The capital of Bengal, where the nabob keeps his court, is Patna or Moorſhedabad. Chandenagore is the principal place poſſeſſed by the French in Bengal; it lies higher up the river than Calcutta. Hugley, which lies fifty miles to the north of Calcutta upon the Ganges, is a place of prodigious trade for the richeſt of all Indian commodities. Dacca is ſaid to be the largeſt city of Bengal, and the tide comes up to its walls. The other chief towns are Caſſumbazar, Chinchura, Barnagua, and Maldo: beſides a number of other places of leſs note, but all of them rich in the Indian manufactures. We know little concerning the province or ſubah of Malva, which lies to the weſt of Bengal, but that it is as fertile as the other provinces, and that its chief cities are Ratiſpor, Ougein, and Indoor. The province of Candiſh includes that of Berar and part of Orixa, and its capital is Brampur, or Burhampoor, a flouriſhing city.

The rivers are, The Cattack or Mahanada, the Soane and Nerbudda, the Pudder, and the famous Kiſtna. This peninſula is rather to be divided into great governments, or ſoubahſhips, than into provinces. One ſoubah often engroſſes ſeveral provinces, and fixes the ſeat of his government according to his own conveniency. I ſhall ſpeak of thoſe provinces as belonging to the Malabar, or Coromandel coaſt, the two great objects of Engliſh commerce in that country; and firſt, of the eaſtern, or Coromandel coaſt. Madura begins at Cape Comorin, the ſouthernmoſt point of the peninſula. It is about the extent of the kingdom of Portugal. Tanjour is a little kingdom, lying on the eaſt of Madura. The ſoil is fertile, within it lies the Daniſh Eaſt India ſettlement of Tranquebar, and the fortreſs of Negapatam, which was taken from the Dutch the laſt war, and confirmed to the Engliſh by the late treaty of peace; the capital city is Tanjour. The Carnatic, as it is now called, is well known to the Engliſh. It is bounded on the eaſt by the bay of Bengal; on the north by the river Kiſtna, which divides it from Golconda; on the weſt by Viſiapour; and on the ſouth by the kingdoms of Meſſaur and Tanjour; being in length, from ſouth to north, about 345 miles, and 276 in breadth from eaſt to weſt. The capital of the Carnatic is Biſnagar, and of our ally, the nabob of Arcot. The country in general is eſteemed healthful, fertile, and populous. Within this country, upon the Coromandel coaſt, lies fort St. David's, or Cuddalore, belonging to the Engliſh, with a diſtrict round it. Five leagues to the north lies Pondicherry, once the emporium of the French in the Eaſt Indies, but which hath been repeatedly taken by the Engliſh, and as often reſtored by the treaties of peace.

Fort St. George, better known by the name of Madras, is the capital of the Engliſh Eaſt India Company's dominions in that part of the Eaſt Indies, and is diſtant eaſtward from London, about 4800 miles. Golconda is ſubject to a prince, called the Nizam, or Soubah of the Deccan. The capital of his dominions is Bagnagur, or Hyderabad, but the kingdom takes its name from the city of Golconda. Eaſt-ſouth-eaſt of Golconda lies Maſulipatan, where the Engliſh and Dutch have factories. The Engliſh have alſo factories at Ganjam and Vizigapatan, on this coaſt; and the Dutch at Narſipore. The province of Orixa, lies to the north of Golconda, extending in length from eaſt to weſt about 550 miles, and in breadth about 240. It is governed chiefly by Moodajee Booſlah, and his brother, allies to the Marattas.

The country of Decan comprehends ſeveral large provinces, and ſome kingdoms; particularly thoſe of Baglana, Balagate, Telenga, and the kingdom of Viſiapour. Modern geographers are not agreed upon their ſituation and extent, but we are told that the principal towns are Aurengabad, and Doltabad or Dowletabad; and the latter is the ſtrongeſt place in all Indoſtan. Near it lies the famous pagod of Flora, in a plain about two leagues ſquare. Telanga lies on the eaſt of Golconda; and its capital is Beder. Baglana lies to the weſt of Telenga, and forms the ſmalleſt province of the empire; its capital is Mouler. The Portugueſe territory begins here at the port of Daman, twenty-one leagues ſouth of Surat, and extends almoſt twenty leagues to the north of Goa. Viſiapour is a large province, the weſtern part is called Konkan. The principal places on this coaſt are, Daman, Baſſaim Trapor or Tarapor, Chawl, Dandi-Rajahhpur, Dabul-Rajupur, Ghiria, and Vingurla. Guzerat is a maritime province on the gulf of Cambaya, and one of the fineſt in India, but inhabited by a fierce rapacious people. It is ſaid to contain 35 cities. Amed-Abad is the capital of the province. About 43 French leagues diſtant lies Surat, where the Engliſh have a flouriſhing factory.

Among the iſlands lying upon the ſame coaſt is that of Bombay, belonging to the Engliſh Eaſt India company. The iſland itſelf is about ſeven miles in length, and twenty in circumference; but its ſituation and harbour are its chief recommendations, being deſtitute

ſtitute of almoſt all the conveniences of life. The town is about a mile long, and poorly built. Near Bombay are ſeveral other iſlands not worth enumerating. The iſland and city of Goa, the capital of the Portugueſe ſettlements in the Eaſt Indies, lie about thirty miles ſouth of Vingurla. The iſland is about twenty-ſeven miles in compaſs. It is one of the fineſt and beſt fortified ports in the Indies. Sunda lies ſouth of the Portugueſe territories, and is governed by a rajah, tributary to the Mogul. The Engliſh factory of Corwar, is one of the moſt pleaſant and healthy of any upon the Malabar coaſt. Kanora lies about forty miles to the ſouth of Goa, and reaches to Calicut. Though Malabar gives name to the old ſouth-weſt coaſt of the peninſula, yet it is confined at preſent to the country ſo called, lying on the weſt of Cape Comorin, and called the dominions of the Samorin. The country itſelf is rich and fertile, but peſtered with green adders, whoſe poiſon is incurable. The moſt remarkable places in Malabar are Kannamore, containing a Dutch factory and fort; Tellicherry, where the Engliſh have a ſmall ſettlement. Calicut, where the French and Portugueſe have ſmall factories, beſides various other diſtinct territories and cities. Cape Comorin is the ſouthernmoſt part of this peninſula, and extends about three leagues.

Modern Perſia is bounded by the mountains of Ararat, or Daghiſtan, which divide it from Circaſſian Tartary, on the North-Weſt; by the Caſpian ſea, which divides it from Ruſſia, on the North; by the river Oxus, which divides it from Uſbec Tartary, on the North-Eaſt; by India, on the Eaſt; and by the Indian ocean, and the gulfs of Perſia and Ormus, on the South; and by Arabia and Turkey, on the Weſt. This kingdom is divided into the following provinces: on the frontiers of India are Coraſan, part of the ancient Hyrcania, including Herat and Eſterabad; Sableuſtan, including the ancient Bactriana and Candahor; and Sigiſtan, the ancient Drangiana. The ſouthern diviſion contains Makeran, Kerman, the ancient Gedroſlia, and Farſiſtan, the ancient Perſia. The ſouth-weſt diviſion, on the frontiers of Turkey, contains the provinces of Chuſiſtan, the ancient Suſiana, and Irac-Agem, the ancient Parthia. The North-weſt diviſion, lying between the Caſpian ſea and the frontiers of Turkey in Aſia, contains the provinces of Aderbeitzen, the ancient Media; Gangea, and Daghiſtan, part of the ancient Iberia and Colchis; Chilan, part of the ancient Hyrcania; Shirvan, and Mazanderan.

Perſia, according to the poets, derived its name from Perſeus, the ſon of Jupiter and Danae. Leſs fabulous authors ſuppoſe it derived from Paras, which ſignifies a horſeman; the Perſians or Parthians, being always celebrated for their ſkill in horſemanſhip. Here are the mountains of Caucaſus and Ararat, which are called the mountains of Daghiſtan: alſo the vaſt collection of mountains called Taurus, and their diviſions, run through the middle of the country from Natolia to India. The moſt conſiderable rivers are thoſe of Kur, anciently Cyrus; and Aras, anciently Araxes, which riſe in or near the mountains of Ararat, and, joining their ſtreams, fall into the Caſpian ſea. The Oxus can ſcarcely be called a Perſian river, though it divides Perſia from Uſbec Tartary. Perſia has the river Indus on the eaſt, and the Euphrates and Tigris on the weſt. Iſpahan or Spahawn, the capital of Perſia, is ſeated on a fine plain within a mile of the river Zenderhend, which ſupplies it with water. It is ſaid to be twelve miles in circumference. Sciras lies about 200 miles to the ſouth of Aſtrachan. It is an open town, and its neighbourhood is inexpreſſibly rich and beautiful. This town is the capital of Pars, the ancient Perſia. The cities of Ormus and Gombroon, on the narrow part of the Perſian Gulf, were formerly places of great commerce and importance

It is remarkable that this country has always preſerved its ancient name. The word *Arab*, it is generally ſaid, ſignifies a robber, or freebooter. The word *Saracen*, by which one tribe is called, is ſaid to ſignify both a thief and an inhabitant of the deſert. They belong to the Arabians, for they ſeldom let any merchandiſe paſs through the country without extorting ſomething from the owners, if they do not rob them. The mountains of Sinai and Horeb, lying in Arabia Petræa, eaſt of the Red Sea, and thoſe called Gabel el Ared, in Arabia Felix, are the moſt noted. There are few mountains, ſprings, or rivers in this country, except the Euphrates, which waſhes the north eaſt limits of it. It is almoſt ſurrounded with ſeas; as the Indian Ocean, the Red ſea, the gulfs of Perſia and Ormus. The chief capes or promontories are thoſe of Roſalgate and Muſledon.

What is called the Deſert of Sinai, is a beautiful plain near nine miles long, and about three in breadth; it lies open to the north-eaſt, but to the ſouthward is cloſed by ſome of the lower eminences of Mount Sinai, and other parts of that mountain makes ſuch encroachments upon the plain as to divide it in two, each ſo capacious as to be ſufficient to receive the whole camp of the Iſraelites. From Mount Sinai may be ſeen Mount Horeb, where Moſes kept the flocks of Jethro, his father-in-law, when he ſaw the burning buſh. The chief cities in Arabia are Mocha, Aden, Muſcat, Suez, and Judah, where moſt of the trade of this country is carried on. Mocha is well built, the houſes very lofty, and are with the walls and forts covered with a chinam or ſtucco, that gives a dazzling whiteneſs to them. The harbour is ſemicircular, the circuit of the walls is two miles, and there are ſeveral handſome moſques in the city. Suez, the Arſinoe of the ancients, is ſurrounded by the Deſert, and but a ſhabby ill-built place. Judah is the place of the greateſt trade in the Red Sea, for there the commerce between Arabia and Europe meets.

At Mecca, the birth place of Mahomet, is a moſque ſo ſuperb, that it is generally counted the moſt magnificent of any temple in the Turkiſh dominions: its lofty roof being raiſed in faſhion of a dome, and covered with gold, with two beautiful towers at the end, of extraordinary height and architecture, make a delightful appearance, and are conſpicuous at a great diſtance. The moſque hath a hundred gates, with a window over each; and the whole building within is decorated with the fineſt gildings and tapeſtry.

The INDIAN *and* ORIENTAL ISLANDS.

The Japan Iſlands form together what has been called the empire of Japan, and are governed by a moſt deſpotic prince, who is ſometimes called emperor, and ſometimes king. They are ſituated about 150 miles eaſt of China, and extend from the 30th to the 41ſt degree of north latitude, and from the 130th to the 147th of eaſt longitude. The chief town is Jeddo, in the 141ſt degree of eaſt longitude, and the 36th of north latitude. The iſlands are very inacceſſible, through their high rocks and tempeſtuous ſeas; they are ſubject to earthquakes, and have ſome volcanoes.

The LADRONE ISLANDS, of which the chief town is ſaid to be Guam, eaſt longitude 140, north latitude 14: they are about twelve in number.

FORMOSA is likewiſe an oriental iſland. It is ſituated to the eaſt of China, near the province of Fo-kien, and is divided into two parts by a chain of mountains, which runs through the middle, beginning at the ſouth coaſt, and ending at the north. This is a very fine iſland, and abounds with all the neceſſaries of life. That part of the iſland which lies to the weſt of the mountains belongs to the Chineſe. The Chineſe have likewiſe made themſelves maſters of ſeveral other iſlands in theſe ſeas, of which we ſcarcely know the names; that of Ainan is between ſixty and ſeventy leagues long, and between fifty and ſixty in breadth, and but twelve miles from the province of Canton.

The PHILIPPINES, of which there are 1100 in number, lying in the Chineſe ſea (part of the Pacific Ocean) 300 miles ſouth-eaſt of China, of which Manilla, or Luconia, the chief, is 400 miles long and 200 broad. The inhabitants conſiſt of Chineſe, Ethiopians, Malays, Spaniards, Portugueſe, Pintados, or painted people, and Meſtes, a mixture of all theſe. The property of the iſlands belongs to the king of Spain.

The MOLUCCAS, commonly called the SPICE or CLOVE ISLANDS. Theſe are not out of ſight of each other, and lie all within the compaſs of twenty-five leagues to the ſouth of the Philippines, in 125 degrees of eaſt longitude, and between one degree ſouth, and two north latitude. They are in number five, viz. Bachian, Machian, Motyr, Ternate, and Tydor. Theſe iſlands after being ſubject to various powers, are now governed by three kings, ſubordinate to the Dutch. Ternate is the largeſt of them though no more than thirty miles in circumference.

The BANDA, or NUTMEG ISLANDS, are ſituated between 127 and 128 degrees eaſt longitude, and between four and five ſouth latitude, comprehending the iſlands of Lantor, the chief towns of which are Lantor, Poleron, Roſinging, Pooloway, and Gonapi. The chief forts belonging to the Dutch on theſe iſlands are thoſe of Revenge and Naſſau.

AMBOYNA. This iſland, taken in a large ſenſe, is one and the moſt conſiderable of the Moluccas, which, in fact, it commands. It is ſituated in the Archipelago of St. Lazarus, between the third and fourth degree of ſouth latitude, and 120 leagues to the eaſtward of Batavia. It is about ſeventy miles in circumference.

The iſland of CELEBES, or MACASSAR, is ſituated under the equator, between the iſland of Borneo and the Spice iſlands, at the

diſtance

diſtance of 160 leagues from Batavia, and is 500 miles long and 200 broad.

The SUNDA ISLANDS. These are ſituated in the Indian Ocean, between 93 and 120 degrees of eaſt longitude, and between eight degrees north and eight degrees ſouth latitude, comprehending the iſlands of Borneo, Sumatra, Java, Bally, Lamboe, Banca, &c.

BORNEO is ſaid to be 800 miles long, and 700 broad, and is therefore thought to be the largeſt iſland in the world except New Holland. The inland part of the country is marſhy and unhealthy; and the inhabitants live in towns built upon floats in the middle of the rivers.

SUMATRA has Malacca on the north, Borneo on the eaſt, and Java on the ſouth-eaſt, from which it is ſeparated by the ſtraits of Sunda; it is divided into two equal parts by the equator, extending five degrees, and upwards, north-weſt of it, and five on the ſouth-eaſt; and is 1000 miles long, and 100 broad. The iſland produces ſo much gold, that it is thought by ſome, to be the Ophir mentioned in the ſcriptures. There is alſo a mountain in the iſland which is called Ophir by the Europeans, whoſe ſummit above the level of the ſea is 13,842 feet, exceeding in height the peak of Teneriff by 577 feet.

The ANDAMAN and NICOBAR iſlands are inconſiderable, and lie at the entrance of the bay of Bengal.

CEYLON. This iſland, though not the largeſt, is thought to be by nature the richeſt and fineſt iſland in the world. It is ſituated in the Indian Ocean, near Cape Comorin: the ſouthern extremity of the Hither Peninſula of India, being ſeparated from the coaſt of Coromandel by a narrow ſtrait, and is 250 miles long, and 200 broad. The natives call it, the terreſtrial paradiſe.

The MALDIVES. Theſe are a vaſt cluſter of ſmall iſlands or little rocks juſt above the water, lying between the equator and eight degrees north latitude, near Cape Comorin. The ſea which ſeparates the ſouthern point of the peninſula of Kamtſchatka from Japan, contains a number of iſlands in a poſition from north-north-eaſt to ſouth-ſouth-weſt, which are called the KURILE ISLANDS. They are upwards of twenty in number, are all mountainous, and in ſeveral of them are volcanos and hot ſprings. The principal of theſe iſlands are inhabited; but ſome of the little ones are entirely deſert and unpeopled.

AFRICA.

Africa, the third grand diviſion of the globe, is generally repreſented as bearing ſome reſemblance to the form of a pyramid, the baſe being the northern part of it, which runs along the ſhores of the Mediterranean, and the point or top of the pyramid, the Cape of Good Hope. Africa is a peninſula of a prodigious extent, joined to Aſia only by a neck of land, about ſixty miles over, between the Red Sea and the Mediterranean, uſually called the Iſthmus of Suez, and its utmoſt length from north to ſouth, from Cape Bona in the Mediterranean, in 37 degrees north, to the Cape of Good Hope in 34-7 ſouth latitude, is 4300 miles; and the broadeſt part from Cape Verd, in 17-20 to Cape Guardafui, near the ſtraits of Babel-Mandel, in 51-20 eaſt longitude, is 3500 miles from eaſt to weſt. It is bounded on the north by the Mediterranean ſea, which ſeparates it from Europe; on the eaſt by the Iſthmus of Suez, the Red Sea, and the Indian Ocean, which divides it from Aſia; on the ſouth by the ſouthern ocean; and on the weſt by the great Atlantic ocean, which ſeparates it from America. As the equator divides this extenſive country almoſt in the middle, and the far greateſt part of it is within the tropics, the heat is in many places almoſt inſupportable to an European; it being there increaſed by the rays of the ſun from vaſt deſerts of burning ſands. The coaſts, however, and banks of rivers, ſuch as the Nile, are generally fertile; and moſt parts of this region are inhabited, though it is far from being ſo populous as Europe or Aſia.

The moſt conſiderable rivers in Africa, are, the Niger, which falls into the Atlantic or weſtern ocean at Senegal, after a courſe of 2800 miles. It increaſes and decreaſes as the Nile, fertiliſes the country, and has grains of gold in many parts of it. The Gambia and Senegal are only branches of this river. The Niel, which dividing Egypt into two parts, diſcharges itſelf into the Mediterranean, after a prodigious courſe from its ſource in Abyſſinia. The moſt conſiderable mountains in Africa are the Atlas, a ridge extending from the weſtern ocean, to which it gives the name of Atlantic Ocean as far as Egypt. The Mountains of the Moon, extending themſelves between Abyſſinia and Monomotapa, and are ſtill higher than thoſe of Atlas. Thoſe of Sierra Leona, or the mountain of the Lions, which divide Nigritia from Guinea, and extend as far as Ethiopia. Theſe were ſtyled by the ancients the Mountains of God, on account of their being ſubject to thunder and lightning. The Peak of Teneriffe, which the Dutch make their firſt meridian, is ſaid to be about three miles high in the form of a ſugar-loaf, and is ſituated on an iſland of the ſame name near the coaſt. The moſt noted capes, or promontories, in this country, are Cape Verd, ſo called, becauſe the land is always covered with green trees and moſſy ground. It is the moſt weſterly point of the continent of Africa. The Cape of Good Hope, is the ſouth extremity of Africa, the country of the Hottentots; and at preſent in the poſſeſſion of the Dutch; there is but one ſtrait in Africa, which is called Babel-Mandel, and joins the Red Sea, with the Indian Ocean.

Africa is divided according to the following Table:

	Nations.	Length	Bread.	Square Miles.	Chief Cities.	Diſt. & bear fr. London	Diff. of time fr. Lond.	Religions

Madeiras, ditto — —	1,500	Santa Cruz, Funchal	Portugueſe
Azores, or Weſtern Iſles, ditto	2,000	Angra, St. Michael	Ditto

Having given the reader ſome idea of Africa in general, with the principal kingdoms, and their ſuppoſed dimenſions, we ſhall now conſider it under the three grand diviſions: firſt, Egypt; ſecondly, the ſtates of Barbary, ſtretching along the coaſt of the Mediterranean, from Egypt in the eaſt, to the Atlantic Ocean weſt; and laſtly, that part of Africa, between the tropic of Cancer and the Cape of Good Hope.

Miles.	— EGYPT. —	Degrees.	Sq. Miles
Length 600 Breadth 250	lies between	20 and 32 North lat. 28 and 36 Eaſt lon.	140,700

It is bounded by the Mediterranean Sea, North; by the Red Sea, Eaſt; by Abyſſinia, or the Upper Ethiopia, on the South; and by the deſert of Barca, and the unknown parts of Africa, Weſt.

Diviſions.	Subdiviſions.	Chief Towns.
Northern diviſion contains	Lower Egypt	GRAND CAIRO, E. lon. 32. N. lat. 30. Bulac, Alexandria Roſetto, Damietta
So. diviſion contains	Upper Egypt	Sayd or Thebes, Coſſiar

Alexandria, which lies on the Levant coaſt, was once the emporium of all the world. It owes its name to the founder, Alexandria the Great. It ſtands forty miles weſt from the Nile, and a hundred and twenty north weſt of Cairo. Roſetta, or Raſchid, ſtands twenty five miles to the north weſt of Alexandria, and is recommended for its beautiful ſituation, and delightful proſpects, which command the iſland of Delta, formed by the Nile, near its mouth. Cairo, the preſent capital of Egypt, is a large and populous, but a diſagreeable reſidence, on account of its peſtilential air, and its narrow ſtreets. It is divided into two towns, the Old and the New, and defended by an old caſtle, the works of which are ſaid to be three miles in circumference. The other towns of note in Egypt are Damietta, ſuppoſed to be the ancient Peluſium; Bulac; Seyd, on the weſt banks of the Nile, 200 miles ſouth of Cairo, ſaid to be the ancient Egyptian Thebes. In April and May the air is hot, and often infectious; and the inhabitants are almoſt blinded with drifts of ſand. Theſe evils are remedied by the riſing and overflowing of the Nile. Whoever is in the leaſt acquainted with literature, knows that the vaſt fertility of Egypt is not owing to rain (little falling in that country), but to the annual overflowing of the Nile. It begins to riſe when the ſun is vertical in Ethiopia, and the annual rains fall there, viz. from the latter end of May to September, and ſometimes October. At the height of its flood in the Lower Egypt, nothing is to be ſeen in the plains, but the tops of foreſts and fruit trees, their towns and villages being built upon eminences either natural or artificial. When the river is at its proper height, the inhabitants celebrate a kind of jubilee, with all ſorts of feſtivities.

The States of BARBARY.

Under this head I ſhall rank the countries of Morocco and Fez; Algiers; Tunis; Tripoli and Barca. The empire of Morocco, including Fez, is bounded on the North by the Mediterranean ſea; on the South, by Tafilet: and on the Eaſt, by Segelmeſſa and the kingdom of Algiers; being 500 miles in length, and 480 in breadth. Fez, which is now united to Morocco, is about 125 miles in length and much the ſame in breadth. It lies between the kingdom of Algiers to the Eaſt, and Morocco on the South, and is ſurrounded in other parts by the ſea. Algiers, formerly a kingdom, is bounded on the Eaſt by the kingdom of Tunis, on the North by the Mediterranean, on the South by Mount Atlas, and on the Weſt by the kingdom of Morocco and Tafilet. According to Dr. Shaw, this country extends in length 480 miles along the coaſt of the Mediterranean, and is between 40 and 100 miles in breadth. Tunis is bounded by the Mediterranean on the North and Eaſt; by the kingdom of Algiers on the Weſt; and by Tripoli with part of Biledulgerid, on the South; being 220 miles in length from North to South, and 170 in breadth from Eaſt to Weſt. Tripoli, including Barca, is bounded on the North by the Mediterranean ſea; on the South by the country of the Beriberies; on the Weſt by the kingdom of Tunis, Biledulgerid, and a territory of the Gadamis; and on the Eaſt by Egypt; extending about 1100 miles along the ſea-coaſt; and the breadth is from 1 to 300 miles. Each capital bears the name of the ſtate or kingdom to which it belongs. Morocco is the capital of the kingdom of Morocco, but now almoſt in ruins, the court having removed to Mequinez, a city of Fez.

The city of Algiers is not above a mile and a half in circuit. The proſpect of the country and ſea from Algiers is very beautiful, being built on the declivity of a mountain; but the city, though for ſeveral ages it has braved ſome of the greateſt powers in Chriſtendom, could make but a faint defence againſt a regular ſiege. The mole of the harbour is 500 paces in length, extending from the continent to a ſmall iſland where there is a caſtle and large battery. The kingdom of Tunis, which is naturally the fineſt of all theſe ſtates, contains the remains of many noble cities, ſome of them ſtill in good condition. The town itſelf has fortifications, and is about three miles in circumference; but like Algiers, is diſtreſſed for want of freſh water. The city of Tripoli conſiſts of an old and new town, the latter being the moſt flouriſhing: but great inconviences attend its ſituation, particularly the want of ſweet water: the city of Oran, lying upon this coaſt, is about a mile in circumference, and is fortified both by art and nature. It was a place of conſiderable trade, and the object of many bloody diſputes between the Spaniards and the Moors. Conſtantina was the ancient Cirta, and one of the ſtrongeſt cities of Numidia, being inacceſſible on all ſides, excepting the ſouth-weſt.

Beſides the above towns and cities, many others, formerly of great renown, lie ſcattered up and down this immenſe tract of country. The city of Fez, at preſent is the capital of the kingdom ſo called. Mequinez is eſteemed the great emporium of all Barbary. Sallee was formerly famous for the piracies of its inhabitants. Tangier is ſituated about two miles within the ſtraits of Gibraltar. It was formerly one of the fineſt cities of Africa, but is now little better than a fiſhing town. Ceuta, upon the ſame ſtrait, almoſt oppoſite to Gibraltar, is in the hands of the Spaniards. Tetuan, which lies within twenty miles of Ceuta, is now but an ordinary town, though the inhabitants are ſaid to be rich, and tolerably civilized in their manners. The provinces of Suz, and Geſula, form no part of the ſtates of Barbary, though the king of Morocco pretends to be their ſovereign.

Of AFRICA, from the Tropic of Cancer to the Cape of Good-Hope.

This immenſe territory is little known; no modern traveller having penetrated into the interior parts; ſo that we are ignorant not only of the bounds, but even of the names of ſeveral inland countries. The countries of Mandingo, Ethiopia, Congo, Angola, Batua, Truticui, Monomotapa, Caſatia, and Mehenemugi, are extremely rich in gold and ſilver. On the Guinea or weſtern coaſt, the Engliſh trade to James Fort, and other ſettlements near the river Gambia, where they exchange their woollen and linen manufactures, their hard ware and ſpirituous liquors, for the perſons of the natives. Among the Negroes, a man's wealth conſiſts in the number of his family, whom he ſells like ſo many cattle, and often at an inferior price. The Portugueſe are in poſſeſſion of the eaſt and weſt coaſt of Africa, from the Tropic of Capricon to the Equator; which immenſe tract they became maſters of by their ſucceſſive attempts and happy diſcovery and navigation of the Cape of Good Hope. The Dutch have ſettlements towards the ſouthern parts of the continent, in the country called Caffraria, or the land of the Hottentots, where their ſhips bound for India uſually put in.

AFRICAN ISLANDS.

Of the African iſlands, ſome lie in the Eaſtern or Indian Ocean, and ſome in the Weſtern, or Atlantic. We ſhall begin with thoſe in the Indian Ocean, the chief of which are Zocotra, Babelmandel, Madagaſcar, the Comora Iſlands, Bourbon, and Mauritius.

ZOCOTRA. This iſland is ſituated in eaſt lon. 53. north lat. 12. 30 leagues eaſt of Cape Guardafui, on the continent of Africa; it is 80 miles long, and 54 broad, and has two good harbours, where the European ſhips uſed formerly to put in when they loſt their paſſage to India. It is a populous plentiful country. The inhabitants are Mahometans, of Arab extraction, and are under the government of a prince who is probably tributary to the Porte.

BABELMANDEL. The iſland of Babelmandel gives name to the ſtraits at the entrance of the Red Sea, where it is ſituated in eaſt lon 44-30. north lat. 12. about four miles both from the Arabian and Abyſſinian ſhores. The iſland is of little value, being a barren ſandy ſpot of earth not five miles round.

COMORA. Theſe iſlands are five, Joanna, Mayotta, Mohilla, Angazeia, and Comora, ſituated between 41 and 46 eaſt long. and between 10 and 14 ſouth lat. at an equal diſtance from Madagaſcar and the continent of Africa. Joanna, the chief, and which exacts tribute from the others, is about 30 miles long and 15 broad, Eaſt India ſhips, bound to Bombay, uſually touch here for refreſhments.

MADAGASCAR. This is the largeſt of the African iſlands, and is ſituated between 43 and 51 deg. eaſt long. and between 10 and 26 ſouth lat. 300 miles ſouth eaſt of the continent of Africa; it being near 1000 miles in length from north to ſouth; and generally between 2 and 300 miles broad.

MAURITIUS, or Maurice, was ſo called by the Dutch, who firſt touched here in 1598, in honour of prince Maurice their ſtadtholder. It is ſituated in eaſt long. 56, ſouth lat. 20, about 400 miles eaſt of Madagaſcar. It is of an oval form, about 150 miles in circumference, with a fine harbour.

BOURBON. The iſle of Bourbon is ſituated in eaſt long. 54, ſouth lat. 21, about 300 miles eaſt of Madagaſcar, and is about 90 miles round. On the ſouthern extremity of the coaſt is a volcano, which continually throws out flames, ſmoke, and ſulphur, with a hideous roaring noiſe. There are conſiderable towns in the iſland, with a governor. There are many more ſmall iſlands about Madagaſcar, and on the eaſtern coaſt of Africa, laid down in maps, but no where deſcribed. Leaving therefore the eaſtern world and the Indies, we now turn round the Cape of Good Hope, which opens to our view the Atlantic, an immenſe ocean lying between the two grand diviſions of the globe, having Europe, Aſia, and Africa, on the eaſt; and America, on the weſt: towards which diviſions we now ſteer our courſe, touching in our way at the following iſlands upon the African coaſt, that have not yet been deſcribed, viz. St. Helena, Aſcenſion, St. Matthew, St. Thomas, &c. Goree, Cape Verd, the Canary and Madeira iſlands.

St. HELENA. The firſt iſland on this ſide the Cape is St. Helena, ſituated in weſt lon. 6-4, ſouth lat. 16, being 1200 miles weſt of the continent of Africa, and 1800 eaſt of South America. The iſland is a rock about 21 miles in circumference, very high and very ſteep, and only acceſſible at the landing place, in a ſmall valley at the eaſt ſide of it.

ASCENSION. This iſland is ſituated in 7 deg. 40 min. ſouth lat. 600 miles north-weſt of St. Helena: it received its name from its being diſcovered by the Portugueſe on Aſcenſion day; and is a mountainous barren iſland, about 20 miles round, and uninhabited.

St. MATTHEW. This is a ſmall iſland, lying in 6-1 weſt lon. and 1-30 ſouth lat. 300 miles on the north eaſt of Aſcenſion. This iſland remains uninhabited. The four following iſlands, viz. St. THOMAS, ANABOA, PRINCES ISLAND, and FERNANDO PO, are ſituated in the gulf of Guinea, between Congo and Benin; all of them are in the poſſeſſion of the Portugueſe.

CAPE VERD ISLANDS. Theſe iſlands are ſo called from a cape of that name on the African coaſt, near the river Gambia, over againſt which they lie, at the diſtance of 300 miles, between 21 and 26 deg. weſt lon. and 14 and 18 deg. north lat. They are about 20 in number; but ſome of them being only barren uninhabited rocks, are not worth notice. St. Jago, Bravo, Fogo, Mayo, Bonaviſta, Sal, St. Nicholas, St. Lucia, St. Vincent, Santa Cruz, and St. Antonio, are the moſt conſiderable, and are ſubject to the Portugueſe.

GOREE is ſituated within cannon-ſhot of Cape Verd. N. lat. 14-43, W. long. 17-20, and was ſo called by the Dutch from an iſland and town of the ſame name in Holland.

CANARIES. The Canaries, anciently called the Fortunate Iſlands, are ſeven in number, and ſituated between 12 and 19 deg. weſt long. and between 27 and 29 deg. north lat. about 150 miles ſouth-weſt of Morocco. Their particular names are Palma, Hiero, Gomera, Teneriffe, Grand Canaria, Fuerteventura, and Langarote. Grand Canary, which communicates its name to the whole, is about 150 miles in circumference, and ſo extremely fertile

Long. East from London

London
I C A
London

tile as to produce two harveſts in a year. Teneriffe, the next largeſt iſland is about 120 miles round: it is pretty much encumbered with mountains, particularly the Peak, which in clear weather may be eaſily diſcerned at 120 miles diſtance, and in ſailing from it at 150. The Peak is an aſcent in the form of a ſugar-loaf, about 15 miles in circumference, and ſaid to be three miles perpendicular. This mountain is a volcano.

MADEIRAS. The three iſlands called the Madeiras, are ſituated in 32-27 north lat. and from 18-30 to 19-30 weſt long. about 100 miles north of the Canaries, and as many weſt of Sallee, in Morocco. The largeſt, from which the reſt derive the general name of Madeiras, or rather Mattera, on account of its being formerly almoſt covered with wood, is about 75 miles long, 60 broad, and 180 in circumference. It is compoſed of one continued hill, of a conſiderable height, extending from eaſt to weſt. There is but one conſiderable town in the whole iſland, which is named Funchal, ſeated on the ſouth part of the iſland, at the bottom of a large bay. The Portugueſe are almoſt the only people who inhabit it.

The AZORES, or, as they are called, the Weſtern Iſlands, are ſituated between 25 and 32 deg. weſt long. and between 37 and 40 north lat. 900 miles weſt of Portugal, and as many eaſt of Newfoundland, lying almoſt in the mid-way between Europe and America. They are nine in number, and are named Santa Maria, St. Miguel or St. Michael, Tercera, St. George, Gracioſa, Fayal, Pico, Flores, and Corvo. It is ſaid that no poiſonous or noxious animal breeds on the Azores, and that if carried thither they will expire in a few hours.

AMERICA IN GENERAL.

This great weſtern continent, frequently denominated the NEW WORLD, extends, from the 80th degree North, to the 56th degree South latitude; and where its breadth is known, from the 55th to the 136th degree of weſt longitude from London; ſtretching between 8 and 9000 miles in length, and in its greateſt breadth 3690. It ſees both hemiſpheres, has two ſummers, and a double winter, and enjoys all the variety of climates which the earth affords. It is waſhed by the two great oceans. To the eaſtward it has the Atlantic, which divides it from Europe and Africa. To the weſt it has the Pacific, or great South Sea, by which it is ſeparated from Aſia. By theſe ſeas it may, and does, carry on a direct commerce with the other three parts of the world. It is compoſed of two great continents, one on the North, the other on the South, which are joined by the kingdom of Mexico, which forms a ſort of iſthmus 1500 miles long, and in one part, at Darien, ſo extremely narrow, as to make the communication between the two oceans, by no means difficult, being only 60 miles over. In the great gulf, which is formed between the iſthmus and the northern and ſouthern continents, lie a multitude of iſlands, many of them large, and moſt of them fertile, and denominated the Weſt Indies, in contradiſtinction to the countries and iſlands of Aſia, beyond the Cape of Good Hope, which are called the Eaſt Indies.

Though America in general be not a mountainous country, it has the greateſt mountains in the world. In South America, the Andes, or Cordelleras, run from north to ſouth along the coaſt of the Pacific Ocean. They exceed in length any chain of mountains in the other parts of the globe; extending from the iſthmus of Darien to the ſtraits of Magellan, they divide the whole ſouthern parts of America, and run a length of 4300 miles. Their height is as remarkable as their length, for though in part within the torrid zone, they are conſtantly covered with ſnow. Chimborazo, the higheſt of the Andes, is 20,633 feet: of this about 2400 feet from the ſummit are always covered with ſnow. Carazon was aſcended by the French aſtronomers, and is ſaid to be 15,800 feet high. In North America, which is chiefly compoſed of gentle aſcents, or level plains, we know of no conſiderable mountains, except thoſe towards the pole, and that long ridge which lies on the back of the American States, ſeparating them from Canada and Louiſiana, which we call the Apalachian or Alligany mountains. In North America, ſuch is the wiſdom and goodneſs of the Creator of the univerſe, thoſe vaſt tracts of country, ſituated beyond the Apalachian mountains, at an immenſe and unknown diſtance from the ocean, are watered by inland ſeas, called the Lakes of Canada, which not only communicate with each other, but give riſe to ſeveral great rivers, particularly the Miſſiſſippi, running from North to South, till it falls into the gulf of Mexico, after a courſe, including its turnings, of 4500 miles, and receiving in its progreſs the vaſt tribute of the Illinois, the Maſaures, the Ohio, and other great rivers, ſcarcely inferior to the Rhine, or the Danube; and on the North, the river St. Laurence, running a contrary courſe from the Miſſiſſippi, till it empties itſelf into the ocean near Newfoundland; all of them being almoſt navigable to their heads, lay open the inmoſt receſſes of this great continent, and afford a great inlet for commerce. The eaſtern ſide of North America, beſides the noble rivers Hudſon, Delawar, Suſquehana, and Potowmack, ſupplies the ſeveral others of great depth, length, and commodious navigation. South America ſupplies much the two largeſt rivers in the world, the river of Amazons, and the Rio de la Plata, or Plate river. The firſt riſing in Peru, not far from the South Sea, paſſes from Weſt to Eaſt, and falls into the ocean between Brazil and Guiana, after a courſe of more than 3000 miles, in which it receives a prodigious number of great and navigable rivers. The Rio de la Plato riſes in the heart of the country, and having its ſtrength gradually augmented, by an acceſſion of many powerful ſtreams, diſcharges itſelf with ſuch vehemence into the ſea, as to make it taſte freſh for many leagues from land. Beſides theſe there are other rivers in South America, of which the Oronoko is the moſt conſiderable. The multitude of iſlands, which lie between the two continents of North and South America, are divided amongſt the Spaniards, Engliſh, and French. The Dutch indeed poſſeſs three or four ſmall iſlands, which in any other hands would be of no conſequence: and the Danes have one or two, but they hardly deſerve to be named among the proprietors of America. We ſhall now proceed to the particular provinces, beginning with the North; but as Labrador, or New Britain, and the country round Hudſon's Bay, with thoſe vaſt regions towards the pole, are little known, we can only include within the following Table, the colonies that have been formed into regular governments which bring us to the 50th degree of north lat.

The Grand Diviſions of NORTH AMERICA.

BRITISH AMERICA.

NEW BRITAIN, or the country lying round Hudſon's Bay, and commonly called the country of the Eſquimaux, comprehending Labrador, now North and South Wales, is bounded by unknown lands, and frozen ſeas, about the pole, on the North; by the Atlantic ocean, on the Eaſt; by the bay and river of St. Lawrence and Canada, on the South; and by unknown lands on the Weſt. Its length is computed at 850 miles, and 750 broad.

CANADA, or the Province of QUEBEC.

Miles.		Degrees.	Sq. Miles.
Length 600	lies between	61 and 81 weſt long.	100,000
Breadth 200		45 and 52 north lat.	

Bounded by New Britain and Hudſon's Bay, on the North and Eaſt; by Nova Scotia, New England and New York, on the South; and by unknown lands on the Weſt. The principal rivers are, the Outtauais, St. John's, Seguinai, Deſprairies, and Trois Rivers, but they are all ſwallowed up by the river St. Lawrence. This river iſſues from the lake Ontario, and taking its courſe north-eaſt, waſhes Montreal, where it receives the Outtauais, and forms many fertile iſlands. It continues the ſame courſe, and meets the tide upwards of 400 miles from the ſea. After receiving in its progreſs innumerable ſtreams, this great river falls into the ocean at Cape Roſiers, where it is 90 miles broad, and where the cold is intenſe, and the ſea boiſterous. In its progreſs it forms a variety of bays, harbours, and iſlands, many of them fruitful and extremely pleaſant. Here are alſo five lakes, the ſmalleſt of which is a piece of ſweet water, greater than any in the other parts of the world; this is the lake Ontario, which is not leſs than 200 leagues in circumference; Erie, or Oſwego, longer, but not ſo broad, is about the ſame extent. That of the Huron ſpreads greatly in width, and is in circumference not leſs than 300, as is that of Michigan, though, like lake Erie, it is rather long and comparatively narrow. But the lake Superior, which contains ſeveral large iſlands, is 500 leagues in the circuit. All of theſe are navigable by any veſſels, and they all communicate with one another, except that the paſſage between Erie and Ontario is interrupted by a ſtupendous fall or cataract, which is called the Falls of Niagara. The town called Trois Rivieres, or the Three Rivers, is about half way between Quebec and Montreal, and has its name from the three rivers which join their currents here, and fall into the river St. Laurence. Montreal ſtands on an iſland in the river St. Laurence, which is ten leagues in length and four in breadth, at the foot of a mountain which gives name to it, about half a league from the ſouth ſhore, and 170 miles from Quebec.

Miles. — NOVA SCOTIA. — Degrees. Sq. M.

Miles.		Degrees.	Sq. M.
Length 350	lies between	43 and 49 North lat.	57,000
Breadth 250		60 and 67 Eaſt long.	

Bounded by the river St. Laurence on the North; by the gulf of St. Laurence, and the Atlantic ocean, Eaſt; by the ſame ocean, South; and by Canada and New England, Weſt. In the year 1784, this province was divided into *two governments*; the province and government, now ſtyled NEW BRUNSWICK, is bounded on the weſtward of the river St. Croix, by the ſaid river to its ſource, and by a line drawn due north from thence to the ſouthern boundary of the province of Quebec; to the northward by the ſame boundary as far as the weſtern extremity of the Bay de Chaleurs; to the eaſtward by the ſaid bay to the gulf of St. Laurence to the bay called Bay Verte; to the ſouth by a line in the centre of the Bay of Fundy, from the river St. Croix, aforeſaid, to the mouth of the Muſquat River; by the ſaid river to its ſource, and from thence by a due eaſt line acroſs the iſthmus into the Bay Verte, to join the eaſtern lot above deſcribed, including all iſlands with ſix leagues of the coaſt.

The rivers Riſgouche and Nipiſiguit run from Weſt to Eaſt, and fall into the bay of St. Laurence. The rivers of St. John, Paſſamagnadi, Penobſcot, and St. Croix, which run from North to South, fall into Fundy Bay, or the ſea a little to the eaſtward of it. The ſeas adjoining to it are, the Atlantic ocean, Fundy Bay, and the gulf of St. Laurence. The leſſer bays are Chenigto and Green Bay upon the iſthmus, which joins the north part of Nova Scotia to the ſouth; and the bay of Chaleurs on the north-eaſt; the bay of Chedibucto on the ſouth-eaſt; the bay of the iſlands, the ports of Bart, Chebucto, Proſper, St. Margaret, La Heve, port Maltois, port Ryſignol, port Vert, and port Joly, on the ſouth; port la Tour, on the ſouth-eaſt; port St. Mary, Annapolis, and Minas, on the ſouth ſide of Fundy Bay, and port Roſeway, now the moſt populous of all.

UNITED STATES OF AMERICA.

Miles. — NEW ENGLAND. — Degrees. Sq. Miles.

Miles.		Degrees.	Sq. Miles.
Length 550	lies between	41 and 49 north lat.	87,000
Breadth 200		67 and 74 weſt lon.	

Bounded on the North-eaſt by Nova Scotia; on the Weſt by Canada; on the South by New York; and on the Eaſt by the Atlantic.

Diviſions.	Provinces.	Chief Towns.
The N. diviſion, or government.	New Hampſhire.	Portſmouth.
The middle diviſion	Maſſachuſett's Colony	BOSTON, N. lat. 42-25 W. Lon. 70-37.
The ſouth diviſion.	Rhode Iſland, &c.	Newport.
The weſt diviſion.	Connecticut.	New London. Hertford.

Their rivers are, the Connecticut; Thames; Patuxent; Merimac; Piſcataway; Saco; Cuſco; Kennebeque; and Ponobſcot, or Pentagonet. The moſt remarkable bays and harbours are thoſe formed by Plymouth, Rhode Iſland, and Providence plantations; Monument-Bay, Weſt-Harbour, formed by the bending of Cape-Cod; Boſton-Harbour; Piſcataway, and Caſco-Bay. Boſton, the capital of New England, ſtands on a peninſula at the bottom of Maſſachuſett's Bay, about nine miles from its mouth. At the entrance of this bay are ſeveral rocks, which appear above water, and upwards of a dozen ſmall iſlands, ſome of which are inhabited. There is but one ſafe channel to approach the harbour, and that ſo narrow, that two ſhips can ſcarcely ſail through abreaſt. On one of the iſlands of the bay, ſtands Fort William, the moſt regular fortreſs in all the plantations. The greateſt part of the town lies round the harbour, in the ſhape of a half moon; the country beyond it riſing gradually, and affording a delightful proſpect from the ſea. The other towns in New England, are generally neat, well built, and commodiouſly ſituated upon fine rivers, with capacious harbours. Cambridge, in the ſame province, is four miles from Boſton, and has an univerſity, containing two ſpacious colleges, with a well furniſhed library.

Miles. — NEW YORK. — Degrees. — Sq. Miles.

Miles.		Degrees.	Sq. Miles.
Length 300	lies between	40 and 46 north lat.	24,000
Breadth 150		72 and 76 weſt lon.	

New York is bounded on the South and South-weſt by Hudſon's and Delaware rivers, which divide it from New Jerſey and Pennſylvania; on the Eaſt and North-eaſt by New England and the Atlantic Ocean; and on the North-weſt by Canada.

This province, including the iſland of New York, Long Iſland, and Staten Iſland, is divided into the ten following counties:

COUNTIES.—New York, Albany, Ulſter, Ducheſs, Orange, Weſt Cheſter, King's, Queen's, Suffolk, Richmond. CHIEF TOWNS.—New York, Albany, Orange, Weſt Cheſter, Jamaica, Southampton, and Richmond.

NEW JERSEY.

SITUATION AND EXTENT.

Miles.		Degrees.	Sq. Miles.
Length 160	lies between	39 and 43 north lat.	10,000
Breadth 60		74 and 76 weſt long.	

New Jerſey is bounded on the Weſt and South-weſt, by Delaware river and Bay; on the South-eaſt and Eaſt, by the Atlantic Ocean; and by the Sound which ſeparates Staten Iſland from the continent, and Hudſon's river, on the North.

Diviſions.	Counties.	Chief Towns.	
Eaſt Diviſion contains	Middleſex	Perth-Amboy & New-Brunſwick	
	Monmouth	None	
	Eſſex	Elizabeth and Newark	
	Somerſet	None	
	Bergen	Bergen	
Weſt Diviſion contains	Burlington	Burlington	40-8 N. lat. 75-0 W. long.
	Glouceſter	Glouceſter	
	Salem	Salem	
	Cumberland	Hopewell	
	Cape May	None	
	Hunderton	Trenton	
	Morris	Morris	
	Suſſex	None	

The Rivers are the Delaware, Raritan, and Paſſaick, on the latter of which is a remarkable cataract; the height of the rock from which the water falls is ſaid to be about 70 feet perpendicular.

Miles. — PENNSYLVANIA. — Degrees. Sq. Miles.

Miles.		Degrees.	Sq. Miles.
Length 300	lies between	74 and 81 weſt long.	15,000
Breadth 240		39 and 44 north lat.	

Bounded by the country of the Iroquois, or Five Nations, on the North; by Delaware river, which divides it from the Jerſeys, on the Eaſt; and by Maryland, on the South and Weſt; and contains the following counties:

COUNTIES. — Philadelphia, Cheſter, Bucks, Berks, Northampton, Lancaſter, York, Cumberland. CHIEF TOWNS. Philadelphia, Cheſter, Newton, Reading, Eaſton, Lancaſter, York, Carliſle.

Bedford, a county weſtward of the mountains upon Ohio, purchaſed from the Indians in 1761, by Mr. Penn, and eſtabliſhed in 1771.

Beſides the above, there are the three following:

Counties.		Chief Towns.
Newcaſtle	on the Delaware	Newcaſtle
Kent and		Dover
Suſſex		Lewes

which form a diſtinct government, and are now called "the Delaware State," having a preſident, council of nine perſons, and houſe of aſſembly of twenty-one repreſentatives: the judges and other officers of ſtate, civil and military, are choſen by the preſident and general aſſembly. The rivers are, Delaware, the Suſquehanna and Schylkill. This province contains many very conſiderable towns, ſuch as German-Town, Cheſter, Oxford, Radnor, but the city of Philadelphia, which is beautiful beyond any city in America, and in regularity unequalled by any in Europe, totally eclipſes the reſt. It is ſituated 100 miles from the ſea, between two navigable rivers, the Delaware, where it is above a mile in breadth on the north, and the Schuylkill, on the ſouth, which it unites as it were, by running in a line of two miles between them.

MARYLAND.

Miles.		Degrees.	Sq. Miles.
Length 140 Breadth 135	lies between	75 and 80 weſt long. 37 and 40 north lat.	12,000

Bounded by Pennſylvania, on the North; by another part of Pennſylvania, and the Atlantic Ocean, on the Eaſt; by Virginia, on the South; and by the Apalachian mountains on the Weſt. Maryland is divided into two parts by the bay of Cheſapeak, viz. 1. The eaſtern; and 2. The weſtern diviſion.

Diviſions.	Counties.	Chief Towns.
The Eaſt diviſion contains the counties of	Worceſter —	Princeſs Anne
	Somerſet —	Snow Hill
	Dorſet —	Dorſet, or Dorcheſter
	Talbot —	Oxford
	Cecil —	
	Queen Anne's —	Queen's town
	Kent —	Cheſter
The Weſt diviſion contains	St. Mary's county	St. Mary
	Charles	Briſtol
	Prince George	Maſterkout
	Calvert	Abington
	Arundel	Annapolis
	Baltimore county	Baltimore
	Frederic county	

This country is indented with a vaſt number of navigable creeks and rivers; the chief are Patowmac, Pocomoac, Patuxent, Cheptonk, Severn, and Saſſafras.

VIRGINIA.

Miles		Degrees	Sq. M.
Length 750 Breadth 140	lies between	75 and 90 weſt lon. 36 and 40 north lat.	80,000

Bounded by the river Potowmac, which divides it from Maryland, on the North-eaſt; by the Atlantic ocean, on the Eaſt; by Carolina, on the South; and the river Miſſiſſippi, on the Weſt. It may be divided into four parts viz. the North, the Middle, the South, and the Eaſtern diviſion.

Diviſions.	Counties.	Pariſhes.
The north diviſion contains	1. Northumberland	Wincomoca
	2. Lancaſhire —	Chriſt Church
	3. Weſtmoreland	
	4. Richmond —	
	5. Stafford —	St. Paul's
The middle diviſion contains	6. Eſſex —	Farnham
	7. Middleſex —	Chriſt Church
	8. Glouceſter —	Abingdon
	9. King & Queen co	Stratton
	10. King Williamco	St. John's
	11. New Kent	St. Peter's
	12. Elizabeth —	Elizabeth
	13. Warwick —	Denby
	14. York —	York
	15. Princeſs Anne	Lynhaven
The South diviſion contains	16. Norfolk —	Elizabeth
	17. Nanſamund	Chutakuk
	18. Iſle of Wight	Newport
	19. Surry —	Southwark
	20. Prince George	Wayanoke
	21. Charles —	Weſtover
	22. Henrico —	Briſtol
	23. James —	James Town
		WILLIAMSBURG.
Eaſtern diviſion.	24. Acomac county	Acomac

In ſailing to Virginia or Maryland, you paſs a ſtrait between two points of land, called the Capes of Virginia, which opens a paſſage into the bay of Cheſapeak, one of the largeſt and ſafeſt in the whole world; for it enters the country near 300 miles from the ſouth to the north, is about 18 miles broad for a conſiderable way, and ſeven where it is the narroweſt, the waters in moſt places being nine fathoms deep.

NORTH AND SOUTH CAROLINA, WITH GEORGIA.

Miles.		Degrees.	Sq. Miles.
Length 700 Breadth 380	lies between	76 and 91 weſt longitude. 30 and 37 north latitude.	110,000

Bounded by Virginia on the North; by the Atlantic Ocean, on the Eaſt; by the river St. John, which ſeparates Georgia from Florida, on the South; and by the Miſſiſſippi, on the Weſt.

Diviſions.	Counties.	Towns.
North Carolina, contains the counties of	Albemarle —	Edenton
	Bath and Clarendon	Wilmington
The middle diviſion, or South Carolina, contains the counties of	Clarendon in part	St. James
	Craven	Chriſt-Church
	Berkley	
	Colleton	CHARLES-TOWN
	Granville	Port Royal
The South Diviſion contains only	Georgia —	SAVANNAH
		Frederica
		Puriſburgh

The rivers are the Roanoke, or Albemarle river; Pamtico; Neus; Cape Fear, or Clarendon river; Pedee; Santee; Savannah; Alatamaha, or George River; and St. Mary's which divide Georgia from Florida: all which riſe in the Apalachian mountains, and, running eaſt, fall into the Atlantic ocean. The only town in either of the Carolinas worthy of notice is Charles-Town, the metropolis of South Carolina, which for ſize, beauty, and trade, may be conſidered as one of the firſt in North America. It is admirably ſituated at the confluence of two navigable rivers, one of which is navigable for ſhips 20 miles above the town, and for boats and large canoes near 40. The harbour is good in every reſpect, but that of a bar, which hinders veſſels of more than 200 tuns burthen, loaded from entering.

WEST INDIES.

Such of the Weſt India iſlands as are worth cultivating belong to five European powers, viz. Great Britain, Spain, France, Holland and Denmark. The iſlands of the Weſt Indies lie in the form of a bow, or ſemicircle, ſtretching almoſt from the coaſt of Florida north, to the river Oronoque, in the main continent of South America. Some call them the Caribbees, from the firſt inhabitants; though this is a term that moſt geographers confine to the Leeward Iſlands, bnt geographical tables and maps diſtinguiſh them into the Great and Little Antilles. The firſt that we come to belonging to Great Britain, is Jamaica, which lies between the 75th and 79th degrees of weſt longitude from London, and between 17 and 18 north latitude. From the eaſt and weſt it is in length about 140 miles, and in the middle about 60 in breadth, growing leſs towards each end, in the form of an egg. It lies near 4500 miles ſouth-weſt of England. Port Royal was formerly the capital of Jamaica. It ſtood upon the point of a narrow neck of land, which, towards the ſea, formed part of the border of a very fine harbour of its own name; but Kingſton a handſome built town is now the capital. Not far from Kingſton, ſtands St. Jago de la Vega, or Spaniſh town, which, though at preſent inferior to Kingſton, was once the capital of Jamaica, and is ſtill the ſeat of government, and the place where the courts of juſtice are held. As for Savannah it is a ſmall ſea-port.

BARBADOES. This iſland the moſt eaſterly of all the Caribbees, is ſituated in 59 degrees weſt long. and 13 degrees north lat. It is 21 miles in length, and in breadth 14. The capital is Bridgetown, where the governor reſides.

ST. CHRISTOPHER's. This iſland, commonly called by the ſailors St. Kitt's, is ſituated in 62 degrees weſt long. and 17 degrees north lat. about 14 leagues from Antigua, and is twenty miles long and ſeven broad. It has its name from the famous Chriſtopher Columbus, who diſcovered it for the Spaniards.

ANTIGUA. Situated in 61 deg. W. lon. and 17 deg. N. lat. is of a circular form, near 20 miles over every way.

NEVIS AND MONTSERRAT. Two ſmall iſlands, lying between St. Chriſtopher's and Antigua, neither of them exceeding 18 miles in circumference. Both were taken by the French in the year 1782, but reſtored at the peace.

BARBUDA. Situated in 18 deg. N. lat. 35 miles north of Antigua, is 20 miles in length, and 12 in breadth.

ANGUILLA. Situated in 19 deg. N. lat. 60 miles north-weſt of St. Chriſtopher's is about 30 miles long and 10 broed. This iſland is perfectly level.

DOMINICA. Situated in 16 deg. N. lat. and in 62 W. lon. lies about half way between Guadaloupe, and Martinico. It is near 28 miles in length and 13 in breadth: it got its name from being diſcovered by Columbus on a Sunday. It was taken by the French in 1778; but was reſtored again to Great Britain by the late peace.

ST. VINCENT. Situated in 13 deg. N. lat. and 61 deg. W. long. 50 miles north-weſt of Barbadoes, 30 miles ſouth of St. Lucia, is about 24 miles in length, and 18 in breadth. The French got poſſeſſion of it in 1789; but it was reſtored to Great Britain by the late treaty of peace.

GRANADA AND THE GRANADINES. Granada is ſituated in 12 deg. north lat. and 62 deg. weſt long. about 30 leagues ſouth-weſt of Barbadoes, and almoſt the ſame diſtance north of New Andaluſia, or the Spaniſh main. This iſland is ſaid to be 30 miles in length, and 15 in breadth. In July, 1779, the French again made themſelves maſters of this iſland, though it was reſtored to Great Britain by the late treaty of peace.

NEWFOUNDLAND is ſituated to the eaſt of the gulf of St. Lawrence, between 46 and 52 deg. north lat. and between 53 and 59 deg. weſt long. ſeparated from Labrador or New Britain by the Straits of Belleiſle, and from Canada by the bay of St. Lawrence, being 350 miles long, and 200 broad. The chief towns in Newfoundland are Placentia, Bonaviſta, and St. John.

CAPE BRETON. This iſland, ſeated between Newfoundland and Nova Scotia, is in length 110 miles, it has good harbours, particularly that of Louiſburgh, which is near four leagues in circumference; it was ceded to the crown of Great Britain by the peace of 1763, ſince which the fortifications have been blown up, and the town of Louiſburgh diſmantled.

ST. JOHN's. Situated in the Gulf of St. Lawrence, is about 60 miles in length, and 30 or 40 broad, and has many fine rivers; and though lying near Cape Breton and Nova Scotia, has greatly the advantage of both in pleaſantneſs and fertility of ſoil.

BERMUDAS, or SUMMER ISLANDS, are ſituated at a vaſt diſtance from any continent, in 32 deg. north lat. and in 65 degrees weſt long. Their diſtance from the Land's End is computed to be near 1500 leagues, from the Madeiras about 1200, and from Carolina 300. The Bermudas are but ſmall, not containing in all above 20,000 acres; and are very difficult of acceſs, being, as Waller, the poet, expreſſes it, "walled with rocks." The town of St. George, which is the capital, is ſeated at the bottom of a haven in the iſland of the ſame name.

LUCAY's, OR BAHAMIA ISLANDS. The Bahamas are ſituated to the South of Carolina, between 12 and 27 degrees north lat. and 73 and 81 degrees weſt lon. They extend along the coaſt of Florida quite down to the iſle of Cuba; and are ſaid to be 500 in number, ſome of them only mere rocks; but 12 of them are large and fertile: they are, however, almoſt uninhabited, except Providence, which is 200 miles eaſt of the Floridas; though ſome others are larger and more fertile, on which the Engliſh have plantations. Between them and the continent of Florida is the gulf of Bahama, or Florida. The Spaniards captured theſe iſlands during the laſt war, but they were retaken by a detachment from St. Auguſtine, April 7th, 1783.

FALKLAND ISLANDS. Leaving the Bahama and Weſt India iſlands, we ſhall now proceed along the ſouth-eaſt coaſt of America, as far as the 52 deg. of ſouth lat. where the reader, by looking into the Map, will perceive the Falkland Iſlands ſituated near the Straits of Magellan, at the utmoſt extremity of South America.

SPANISH DOMINIONS IN NORTH AMERICA.

EAST AND WEST FLORIDA.

Miles.		Degrees.
Length 500	lies between	80 and 91 weſt longitude.
Breadth 440		25 and 32 north latitude.

This country, which was ceded by Great Britain to Spain by the late treaty of peace, is bounded by Georgia on the North; by the Miſſiſſippi on the Weſt; by the Gulf of Mexico on the South; and by the Bahama Straits on the Eaſt.

The chief river is the Miſſiſſippi, which is one of the fineſt in the world, as well as the largeſt; for, including its turnings and windings, it is ſuppoſed to run a courſe of 4500 miles. The chief bays are St. Bernard's Aſcenſion, Mobille, Penſacola, Dauphin, Joſeph, Apalaxy, Spiritu, Sancto, and Charles Bay. The capes are, Cape Blanco, Samblas, Anclote, and Cape Florida, at the extremity of the peninſula. The chief town in Weſt Florida is Penſacola, N. lat. 30-22 W. long. 87-20, which is ſituated within the bay of the ſame name, on a ſandy ſhore that can only be approached by ſmall veſſels. St. Auguſtine, the capital of Eaſt Florida, N. lat. 29-45 W. long. 81-12, runs along the ſhore, and is of an oblong form. The town is fortified with baſtions, and encloſed with a ditch.

NEW MEXICO, INCLUDING CALIFORNIA.

Miles		Degrees.
Length 2000	lies between	94 and 126 weſt longitude.
Breadth 1600		23 and 43 north latitude

Bounded by unknown lands on the north; by Louiſiana, on the Eaſt; by Old Mexico, and the Pacific Ocean, on the South; and by the ſame ocean on the Weſt.

Diviſions.	Subdiviſions.	Chief Towns.
North-eaſt diviſion	New Mexico Proper	SANTA FE.
South-eaſt diviſion	Apacheira ——	St. Antonio.
South diviſion	Sonora ——	Tuape.
Weſt diviſion	California, a peninſula	St. Juan.

OLD MEXICO, OR NEW SPAIN.

Miles		Degrees.
Length 2000	lying between	83 and 110 Weſt longitude.
Breadth 600		8 and 30 north latitude.

Bounded by New Mexico, or Granada, on the north; by the gulf of Mexico, on the North-eaſt; by Terra Firma, on the South-eaſt; and by the Pacific Ocean, on the South Weſt; containing three audiences, viz.

Audiences.	Chief Towns.
1. Galicia or Guadalajarra. ——	Guadalajarra.
2. Mexico Proper ——	MEXICO, Acapulco, Vera Cruz.
3. Guatimala —— ——	Guatimala

On the north ſea are the gulfs or bays of Mexico, Campeachy, Vera Cruz, and Hondurus; in the Pacific Ocean or South Sea, are the bays Micoya and Amapalla, Acapulco and Salinas.

SPANISH DOMINIONS IN SOUTH AMERICA,

TERRA FIRMA, OR CASTILE DEL ORO.

Miles.		Degrees.
Length 1400	lies between	60 and 82 weſt longitude.
Breadth 700		the equator, and 12 north latitude.

Bounded by the North Sea (part of the Atlantic Ocean), on the North; by the ſame ſea and Surinam, on the Eaſt; by the country of the Amazons and Peru, on the South; and by the Pacific Ocean and New Spain, on the Weſt.

Diviſions.	Subdiviſions.	Chief Towns.
The north diviſion contains the provinces of	1. Terra Firma Proper, or Darien	Porto Bello PANAMA
	2. Carthagena	Carthagena
	3. St. Martha	St. Martha
	4. Rio de la Hacha	Rio de la Hacha
	4. Venezuela	Venezuela
	6. Comana	Comana
	7. New Andaluſia	St. Thomas
The ſouth diviſion contains the provinces of	1. New Granada	Santa Fé de Bagota
	2. Popayan	Popayan.

The iſthmus of Darien, or Terra Firma Proper, joins North and South America. A line drawn from Porto Bello in the North to Panama in the South Sea, or rather a little weſt of theſe two towns, is the proper limit between North and South America, and here the iſthmus or neck of land is only 60 miles over. The principal bays in Terra Firma are, the bay of Panama, and the bay of St. Michael's, in the South Sea; the bay of Porto Bello, the gulf of Darien, Sino bay, Carthagena bay and harbour, the gulf of Venezuela, the bay of Maracaibo, the gulf of Trieſto, the bay of Guaira, the bay of Curiaco, and the gulf of Paria, or Andaluſia, in the North Sea.

PERU.

Miles.		Degrees.
Length 1800	lies between	the equator and 23 ſouth lat.
Breadth 500		60 and 81 weſt long.

Bounded by Terra Firma, on the North; by the mountains, or Cordeleiras des Andes, Eaſt; by Chili, South; and by the Pacific Ocean, Weſt.

Diviſions.	Provinces.	Chief Towns.
The north diviſion	Quito	Quito Payta
The middle diviſion	Lima, or Los Reyes	LIMA, Cuſco, and Callao.
The ſouth diviſion	Los Charcos	Potoſi, Porco.

The only ſea which borders on Peru is the Pacific Ocean, or South Sea. The principal bays and harbours are Payta, Malabrigo, Cuanchaco, Coſma, Vermeio, Guara, Callao the port-town to Lima, Ylo, and Arica. There is a river whoſe waters are as red as blood. The rivers Granada or Cagdalena, Oronoque, Amazon, and Plate, riſe in the Andes, and fall into the Pacific Ocean, between the equator and eight deg. S. lat. The city of Lima is the capital of Peru, and of the whole Spaniſh empire: its ſituation in the middle of a ſpacious and delightful valley, was fixed upon by the famous Pizarro, as the moſt proper for a city, which he expected would preſerve his memory. In the year 1747, a moſt tremendous earthquake laid three-fourths of this city level with the ground, and entirely demoliſhed Callao, the port-town belonging to it. Cuſco, the ancient capital of the Peruvian empire, lies in a mountainous country, and at a diſtance from the ſea, and has been long on the decline.

CHILI.

Miles.		Degrees.
Length 1200	lies between	25 and 45 ſouth latitude.
Breadth 500		65 and 85 weſt longitude.

Bounded by Peru, on the north; by La Plata, on the Eaſt; by Patagonia, on the ſouth; and by the Pacific Ocean, on the Weſt.

Diviſions.	Provinces.	Chief Towns.
On the weſt ſide of the Andes.	Chili Proper.	St. Jago, Baldivia
On the eaſt ſide of the Andes.	Cuyo, or Cutio.	St. John d'Frontiera

The principal lakes are thoſe of Tagatagua near St. Jago, and that of Paren. Beſides which they have ſeveral ſalt-water lakes, that have a communication with the ſea, part of the year.

PARAGUAY, OR LA PLATA.

Miles.		Degrees.
Length 1500	lies between	12 and 37 ſouth latitude.
Breadth 1000		50 and 75 weſt longitude.

Bounded by Amazonia, on the north; by Brazil, Eaſt; by Patagonia, on the ſouth; and by Peru and Chili, Weſt.

Diviſions.	Provinces.	Chief Towns.
Eaſt diviſion contains	Paraguay	Aſſumption
	Parana	St. Anne
	Guaira	Civadad Real
	Uragua	Los Reyes
South diviſion	Tucuman	St. Jago
	Rio de la Plata	BUENOS AYRES.

The principal bay is that at the mouth of the river La Plata, on which ſtands the capital city of Buenos Ayres; and Cape St. Antonio, at the entrance of that bay, is the only promontory. This country abounds with lakes, one of which is 100 miles long. This country, beſides an infinite number of ſmall rivers, is watered by three principal ones, which, united near the ſea, form the famous Rio de la Plato, or Plate River, and which annually overflow their banks: and, on their receſs, leave them enriched with a ſlime, that produces the greateſt plenty of whatever is committed to it. The Spaniards firſt diſcovered this country, by ſailing up the river la Plata in 1515, and founded the town of Buenos Ayres, ſo called on account of the excellence of the air, on the ſouth ſide of the river, fifty leagues within the mouth of it, where the river is ſeven leagues broad. This is one of the moſt conſiderable towns in South America.

SPANISH ISLANDS IN AMERICA.

CUBA. The iſland of Cuba is ſituated between 19 and 23 degrees north lat. and between 74 and 87 degrees weſt lon. 100 miles to the ſouth of Cape Florida, and 75 north of Jamaica, and is near 700 miles in length, and generally about 70 miles in breadth. A chain of hills runs through the middle of the iſland from eaſt to weſt; but the land near the ſea is in general level and flooded in the rainy ſeaſon when the ſun is vertical.

HISPANIOLA, or St. DOMINGO. This iſland was at firſt poſſeſſed by the Spaniards alone; but by far the moſt conſiderable part is now in the hands of the French. However, as the Spaniards were the original poſſeſſors, and ſtill continue to have a ſhare in it, Hiſpaniola is commonly regarded as a Spaniſh iſland. It is ſituated between the 17th and 21ſt degrees north lat. and the 67th and 74th of weſt lon. lying in the middle between Cuba and Porto-Rico, and is 450 miles long, and 150 broad. The moſt ancient town in this iſland, and in all the New World, built by Europeans, is St. Domingo. It was founded by Bartholomew Columbus, brother to the admiral, in 1504, who gave it that name in honour of his father Dominic, and by which the whole iſland is ſometimes named, eſpecially by the French. It is ſituated on a ſpacious harbour, and is a large well-built city.

The French towns are Cape St. Francois the capital, Leogane, Petit Guaves, and Port Louis.

PORTO RICO. Situated between 64 and 67 degrees weſt lon. and in 18 degrees north lat. lying between Hiſpaniola and St. Chriſtopher's, is 100 miles long, and 40 broad. Porto Rico, the capital town, ſtands in a little iſland on the north ſide of the main iſland, forming a capacious harbour, and joined to the chief iſland by a cauſey, and defended by forts and batteries, which render the town almoſt inacceſſible.

VIRGIN ISLANDS. Situated at the eaſt end of Porto Rico, are extremely ſmall.

TRINIDAD. Situated between 59 and 62 degrees weſt lon. and in 10 degrees north lat. lies between the iſland of Tobago and the Spaniſh Main; from which it is ſeparated by the ſtreights of Paria. It is about 90 miles long, and 60 broad; and is an unhealthful ſoil.

MARGARETTA. Situated in 64 degrees weſt lon. and 11-30 north lat. ſeparated from the northern coaſt of New Andaluſia, in Terra Firma, by a ſtrait of 24 miles, is about forty miles in length, and 24 in breadth; and being always verdant, affords a moſt agreeable proſpect.

JUAN FERNANDES. Lying in 83 degrees weſt lon. and 33 ſouth lat. 300 miles weſt of Chili. This iſland is uninhabited: but is famous for having given riſe to the celebrated romance of Robinſon Cruſoe.

PORTUGUESE AMERICA. — CONTAINING BRAZIL.

Miles		Degrees.
Length 2500	lies between	the equator and 35 ſouth latitude
Breadth 700		35 and 60 weſt longitude.

Bounded by the mouth of the river Amazon, and the Atlantic Ocean, on the north; by the ſame ocean on the eaſt; by the mouth of the river Plata ſouth; and by a chain of mountains, which divide it from Paraguay and the country of Amazons on the weſt. On the coaſt are three ſmall iſlands, where ſhips touch for proviſions in their voyage to the South Seas, viz. Fernando, St. Barbara, and St. Catherine's. The Atlantic Ocean waſhes the coaſt of Brazil on the north-eaſt and eaſt, upwards of 3000 miles, forming ſeveral fine bays and harbours: as the harbours of Panambuco, All Saints, Porto Seguro, the port and harbour of Rio Janeiro, the port of St. Vincent, the harbour of St. Gabriel, and the port of St. Salvador, on the north ſhore of the river la Plata. St. Salvador, or the city of Bahia, the capital, commands a noble, ſpacious, and commodious harbour. It is built upon a high and ſteep rock, having the ſea upon one ſide, and a lake, forming a creſcent, inveſting it almoſt wholly ſo as nearly to join the ſea, on the other. The ſituation makes it in a manner impregnable by nature; and they have beſides added to it very ſtrong fortifications.

FRENCH ISLANDS IN AMERICA.

MARTINICO. Which is ſituated between 14 and 15 deg. of north lat. and in 61 degrees weſt lon. lying about 40 leagues north-weſt of Barbadoes, is about 60 miles in length, and half as much in breadth. The inland part of it is hilly, from which flow upon every ſide, a number of agreeable and uſeful rivers, which adorn and enrich this iſland in a high degree.

GUADALOUPE. So called by Columbus, from the reſemblance of its mountains to thoſe of that name in Spain, is ſituated in 16 degrees north lat. and in 62 weſt lon. about 30 leagues north of Martinico, and almoſt as much ſouth of Antigua; being 45 miles long, and 38 broad. It is divided into two parts by a ſmall arm of the ſea, or rather a narrow channel, through which no ſhips can venture; but the inhabitants paſs it in a ferry-boat.

St. LUCIA. Situated in 14 deg. north lat. and in 61 deg. weſt lon. 80 miles north-weſt of Barbadoes, is 23 miles in length and 12 in breadth.

TOBAGO. This iſland is ſituated in 11 degrees odd min. north lat. 120 miles ſouth of Barbadoes, and about the ſame diſtance from the Spaniſh Main. It is about 32 miles in length, and nine in breadth.

St. BARTHOLOMEW, DESEADA AND MARIGALANTE, are three ſmall iſlands lying in the neighbourhood of Antigua, and St. Chriſtopher's, and are of no great conſequence to the French, except in time of war, when they give ſhelter to an incredible number of privateers, which greatly annoy our Weſt India trade.

DUTCH AMERICA.

Containing SURINAM, on the Continent of SOUTH AMERICA.

Dutch Guiana is ſituated between five and ſeven degrees north lat. extending 100 miles along the coaſt from the mouth of the river Oronoque, north, to the river Maroni, or French Guiana, ſouth. The climate of this country is generally reckoned unwholeſome; and a conſiderable part of the coaſt is low, and covered with water. The chief ſettlement is at Surinam, a town built on a river of the ſame name. Connected with Surinam, we ſhall mention the two Dutch Colonies of Demerary and Iſſequibo on the Spaniſh Main, which ſurrendered to the Engliſh in the year 1781.

DUTCH ISLANDS IN AMERICA.

St. EUSTATIUS. Situated in 17° 29′ N. lat. 63° 10′ W. long. and three leagues north-weſt of St. Chriſtopher's, is only a mountain about 29 miles in compaſs, riſing out of the ſea like a pyramid, and almoſt round. The ſides of the mountain, are laid out in very pretty ſettlements; but they have neither ſprings nor rivers.

CURASSOU. Situated in 12 degrees north lat. 9 or 10 leagues from the continent of Terra Firma, is 30 miles long, and 10 broad. All kinds of labour are here performed by engines: ſome of them ſo well contrived, that ſhips are at once lifted into the dock. The other iſlands, Bonaire and Aruba, are inconſiderable in themſelves, and ſhould be regarded as appendages to Curaſſou. The ſmall iſlands of Saba and St. Martin's, ſituated at no great diſtance from St. Euſtatia, hardly deſerve to be mentioned; they were both captured by admiral Rodney and General Vaughan, at the time when St. Euſtatia ſurrendered to the arms of Great Britain; but were afterwards retaken by the French.

DANISH ISLANDS IN AMERICA.

St. THOMAS. An inconſiderable member of the Caribbees, ſituated in 64 degrees weſt lon. and 18 north lat. about 15 miles in circumference, and has a ſafe and commodious harbour.

St. CROIX, or SANTA CRUZ. Another ſmall and unhealthy iſland, lying about five leagues eaſt of St. Thomas, ten or twelve leagues in length, and three or four where it is broadeſt.

TERRA-INCOGNITA, or unknown Countries.

Notwithſtanding the amazing diſcoveries of navigators, and the progreſs made in geography, ſince the firſt voyage of Columbus, anno 1492, there ſtill remain ſome countries, either abſolutely unknown, or very ſuperficially ſurveyed.

IN AFRICA. — Of this quarter of the globe the moderns are acquainted with the ſea-coaſts only, and theſe very imperfectly; the internal parts being little known to us, nor have we any ſatisfactory accounts of their inhabitants, their productions, or their trade. It is well known, however, that the rivers of Africa bring down large quantities of gold, and it is equally certain, that the ancients drew prodigious riches from a country bleſſed with a variety of climates, ſome of them the fineſt in the world.

IN AMERICA. — In North America, towards the Pole, are Labrador, or New Britain, New North, and South Wales, New Denmark, &c. very little known. All that vaſt tract on the back of the Britiſh ſettlements, from Canada and the lakes to the Pacific Ocean, which waſhes America on the weſt, is perfectly unknown to us, no European having ever travelled thither. In South America, the country of Guiana, extending from the equator to the eighth degree of north latitude, and bounded by the river Oronoque on the north, and the Amazons on the ſouth, is unknown, except a ſlip along the coaſt, where the French at Cayenne, and the Dutch at Surinam, have made ſome ſettlements; which from the unhealthfulneſs of the climate, almoſt under the equator, and other cauſes, can hardly be extended any conſiderable way back. The country of Amazonia, ſo called from the great river of that name, has never been thoroughly diſcovered, though it is ſituated near the European colonies of Peru and Braſil, and every where navigable by means of that great river and its branches. Patagonia, at the ſouthern extremity of America, is ſometimes deſcribed as part of Chili: but as neither the Spaniards, nor any other European nation, have any colonies here, it is almoſt unknown, and is generally repreſented as a barren, inhoſpitable country. And here in 52½ degrees ſouth lat. we fall in with the Straits of Magellan, having Patagonia on the north, and the iſlands of Terra del Fuego on the ſouth. Theſe Straits extend from eaſt to weſt 110 leagues, but the breadth in ſome places falls ſhort of one.

Our knowledge of the globe has been conſiderably augmented by the late diſcoveries of the Ruſſians, in the northern Archipelago, and ſtill more by thoſe that have been made Britiſh navigators in the preſent reign, which have been numerous and important; of theſe diſcoveries we ſhall therefore give a compendious account.

NORTHERN ARCHIPELAGO.

This conſiſts of ſeveral groups of iſlands, which are ſituated between the eaſtern coaſt of Kamtſchatka and the weſtern coaſt of the continent of America. Mr. Muller divides theſe iſlands into four principal groups, the two firſt of which are ſtyled the Aleutian iſlands. The firſt group, which is called by ſome of the iſlanders

Saſignan, comprehends, Beering's iſland; Copper Iſland; Otma; Samyra, or Shemvia; Anakta. The ſecond group is called Kaho, and comprizes eight iſlands, viz. Immak; Kiſka; Tchetchia; Ava; Kavia; Tſchangulak; Ulagama; Amtſchidga. The third general name is Neglio, and comprehends the iſlands known to the Ruſſians under the name of Andleanoffski Oſtrova; ſixteen of which are mentioned under the following names: Amatkinak; Ulak; Unalga; Navotſha; Uliga; Anagin; Kagulak; Illaſk, or Illak; Takavanga, upon which is a volcano; Kanaga, which has alſo a volcano; Leg; Sketſhuna; Tagaloon; Gorleoi; Otchu; Amla. The fourth group is called Kavalang, and comprehends ſixteen iſlands; which are called by the Ruſſians Lyſſic Oſtrova, or the *Fox Iſlands*; and which are named, Amuchta; Tſchigama; Tſchegula; Uniſtra; Ulaga; Tauagulana; Kagamin; Kigalga; Skelmaga; Umnak; Agun-Alaſhka; Unimma; Uligan; Auturo Leiſſume; Semidit; Senagak.

NEW DISCOVERIES.

In conſequence of an order of his preſent majeſty, for making diſcoveries in the ſouthern hemiſphere, voyages were undertaken, and ſucceſſively performed, by Commodore Byron, Captain Wallis, Captain Carteret, and Captain Cook; the latter of whom accompliſhed a very important purpoſe, in aſcertaining that immenſe tract, in the ſouthern clime, called New Holland, to be an iſland, which had ever before been ſuppoſed continental.

OTAHEITE, or KING GEORGE'S ISLAND.

This iſland was diſcovered by captain Wallis, in the Dolphin, on the 19th of June, 1767. It is ſituated between the 17th degree 28 min. and the 17th degree 53 min. ſouth latitude; and between the 149th degree 11 min. and the 149th degree 39 minutes weſt long. It conſiſts of two peninſulas, of a ſomewhat circular form. joined by an iſthmus, and is ſurrounded by a reef of coral rocks, which form ſeveral excellent bays and harbours, where there is room and depth of water for almoſt any number of the largeſt ſhips; it is known by the general name *Otaheite*, forms two diſtinct kingdoms, which are united by a narrow neck of land. The largeſt of theſe kingdoms is called by the natives *Tiarrabou*, or *Otaheite-nue*; the ſmaller *Opoureonu*, or *Otaheite-Ete*. It is ſurrounded by a reef of coral rocks, forming ſeveral bays, among which the principal is Port Royal, called by the natives Matavai. The country affords a beautiful proſpect. It riſes in ridges, forming mountains in the middle of the iſland that may be ſeen at the diſtance of ſixty miles. Towards the ſea it is level, and covered with fruit trees of divers kinds, but particularly the cocoa-nut. In this part are the houſes of the inhabitants, which do not form villages, being ranged along the whole border at about fifty yards diſtance from each other. The ſoil, which is of a blackiſh colour, being watered by a number of rivulets, is rich, and of courſe luxuriant in its products. On the borders of the valley through which the river flows there are ſeveral houſes with walled gardens, and plenty of fowls and hogs. Channels are cut in many places to conduct the water from the hills to the plantations. Streams meander through various windings, and ſtupendous mountains overhang the vallies. Towards the ſea the view is delightful, the ſides of the hills being covered with trees, and the vallies with graſs. No underwood was found beneath the trees, neither on the ſides or bottoms of the hills, but there was plenty of good graſs. Many fine ſprings guſh from the borders of the mountains, all of which are covered with wood on the ſides, and fern on the ſummits. Sugar cane grows without cultivation on the high land, as do alſo turmeric and ginger.

This iſland is not only one of the moſt delightful but healthy ſpots in the world. The heat is tempered by the pureſt air. It is not ſubject conſtantly to the bleak winds from the eaſt, but generally under the milder breezes from eaſt to ſouth-ſouth-eaſt. From theſe ſingular endowments of nature, this charming ſpot is juſtly denominated "The Queen of Tropical Iſlands." The vegetable productions of this iſland are as various as numerous in their reſpective ſpecies. There are bread fruit, cocoa nuts, bananas of many ſorts, ſweet potatoes, plantains, yams, a delicious fruit known here by the name of *jambu*, ſugar cane, the paper mulberry, ginger termeric, and ſeveral ſorts of figs, all of which the ſoil produces ſpontaneouſly, or with very little culture.

THE SOCIETY ISLANDS. Theſe iſlands, which were diſcovered and ſo called by Captain Cook in the year 1769, compoſe a group of ſix in number, under the following names, by which they are called by the natives, viz. Huaheine, Ulietea, or Raietea, Bolabola, Otaha, Tubai and Mawrua, or Moroua. They lie contiguous between the latitude of 16 deg. 10 min. and 16 deg. 55 min. ſouth, and between the longitude of 150 deg. 57 min. and 152 deg. weſt. The luxuriant productions of theſe iſlands, and benevolent diſpoſition of the natives, are highly celebrated by different voyagers. The country is richly endowed by nature, and the people, as poſſeſſing an extreme liberality of mind, evinced in a more particular manner by their chearfully contributing to ſupply the wants of ſuch navigators whom chance or deſign might direct to this hoſpitable ſpot. Nor are they leſs friendly than munificent, as appeared from the very condeſcending aſſiduities ſhewn to their European viſitors. In a word, their hoſpitality upon every occaſion appeared ſo diſtinguiſhed, that it is mentioned as a virtue worthy not only of the warmeſt commendation, but preciſe imitation of the moſt civilized parts of the globe. The propriety, therefore, of the appellation given them by Captain Cook is clearly evident.

The iſland of Huaheine is the principal, it was diſcovered by Captain Cook two days after his departure from Otaheite, in 1769, lies in latitude 16 deg. 43 min. ſouth, and longitude 150 deg. 52 min. weſt. It is about 30 leagues diſtant from Otaheite, and about 20 miles in circumference, having a commodious harbour on the weſt ſide. It is divided into two peninſulas, joined by an iſthmus, which at high water is overflowed; it ſeems to have been diſturbed by volcanoes; and the face of the country reſembles that of Otaheite. The level part of this iſland is very fertile, and abounds with bread-fruit and cocoa-nut trees, yams, plantains; and its productions are more forwardthan thoſe at Otaheite; they have alſo hogs, and fowls.

FRIENDLY ISLANDS are thoſe under which we muſt include not only Tongataboo, Eaoo, and Annamooka, which were ſo named by Capt. Cook, in 1773, on account of the friendſhip that ſubſiſted among the inhabitants, and their courteous behaviour towards ſtrangers; but alſo the group at Hapaee, viſited by him in 1777, and all the iſlands that have been diſcovered, nearly under the ſame meridian, from Pilſtart, diſcovered by Taſman, in lat. 22-26. S. down to Boſcawen's and Keppel's iſles, diſcovered by Wallis, in lat. 15-53. and thence weſtward to Taſman's Prince William's iſlands, in long. 179 W. Within theſe limits the Archipelago will be found to be very extenſive. Above 150 iſlands are reckoned up by the natives, who aſſign its proper name to each. Fifteen of them are ſaid to be high: 35 larger than Annamooka, and the reſt ſmall; many of them, perhaps, mere ſpots without inhabitants. Sixty-one of theſe iſlands are laid down in Capt. Cook's chart of the Friendly Iſlands. The three firſt mentioned were diſcovered by Taſman in 1642, and by him called Amſterdam, Middleburgh, and Rotterdam. They were twice viſited by Capt. Cook in 1773, and 1774; and in 1777, Hapaee was added to the number. Theſe extend from north to ſouth, between the lat. of 19-39. and 21-30. S. and between the long. 174-15. and 175-18. W. They are interſperſed with many ſmaller iſlands. The general appearance of theſe iſlands conveys an idea of the moſt exuberant fertility; the ſurface, at a diſtance, ſeems entirely clothed with trees of various ſizes, ſome of which are very large, particularly the tall cocoa-palm, and a ſpecies of fig with narrow-pointed leaves. On cloſer examination, it is almoſt wholly laid out in plantations, in which are planted ſome of the richeſt productions of nature; ſuch as bread-fruit, cocoa-nut trees, plantains, bananas, ſhadocks, yams, and ſome other roots, ſugar-cane, and a fruit like a nectarine. In ſhort, here are moſt of the articles which the Society Iſlands produce, and ſome alſo which they have not. Their ſtock of quadrupeds is as ſcanty as that of the Society Iſlands; but they received from Capt. Cook the ſame valuable additions, both to the animal and vegetable kingdom. Their domeſtic fowls are as large and as good as thoſe of Europe. Among the birds are parrots and parroquets of various ſorts, which furniſh the red feathers ſo much eſteemed at the Society Iſles. The ſea abounds with fiſh, and the numerous reefs and ſhoals afford ſhelter for an endleſs variety of ſhell-fiſh. Agriculture, architecture, boat-building, and fiſhing, are the employments of the men; the province of the women is far leſs laborious, for to their care is confined the manufacture of their cloth.

It was natural to ſuppoſe, on a review of theſe iſlands, and the remote diſtance at which ſome of them are ſituated from the ſeat of government, that many efforts would have been made to throw of the yoke of ſubjection. But ſuch a circumſtance never happens. One reaſon of their not being thus embroiled in domeſtic commotions may be this, that all the principal chiefs take up their reſidence at Tongataboo. They alſo ſecure the dependance of the other iſles, by the deciſive celerity of their operations; for if a ſeditious and popular man ſhould ſtart up in any of them, the commander is immediately diſpatched thither to put him to death, by which means they extinguiſh an inſurrection while it is yet in embryo. The tides are more conſiderable at the Friendly Iſlands than at any other of Captain Cook's diſcoveries, in this ocean, that are ſituate within either of the tropics. At Annamooka the tide riſes and falls about ſix feet upon a perpendicular. At Tongataboo it riſes and falls four feet and three quarters on the full and change days, and three feet and an half at the quadratures.

THE NEW HEBRIDES. This name was given by captain Cook to a cluſter of iſlands, the moſt northerly of which was ſeen by Quiros, the Spaniſh navigator, in 1606, and by him named Tierra del Eſpiritu Santo. From that time till captain Cook's voyage in the Endeavour, in 1769, this land was ſuppoſed to be part of a great ſouthern continent, called *Terra Auſtralis incognita*. But when captain Cook had ſailed round New Zealand, and along the eaſtern coaſt of New Holland, this opinion was fully confuted. The Hebrides are ſituated between the latitudes of 14 deg. 29 min. and 20 deg. 4 min. ſouth; and between 66 deg. 41 min. and 170 deg. 21 min. eaſt longitude. They conſiſt of the following iſlands, ſome of which have received names from the different European navigators, and others retain the names which they bear among the natives, viz. Tierra del Eſpiritu Santo, Mallicollo, St. Bartholomew, Iſle of Lepers, Aurora, Whitſuntide, Ambrym, Immer, Appee, Three Hills, Sandwich, Montagu, Hinchinbrook, Shepherd, Eorromanga, Irronan, Annatom, and Tanna. Captain Cook, beſides aſcertaining the extent and ſituation of theſe iſlands, added the knowledge of ſeveral in this groupe that were before unknown. He explored the whole cluſter, and thence claiming a right to affix to them a general appellation, named them THE NEW HEBRIDES.

During captain Cook's continuance at Tanna, a volcano emitted, at different times, vaſt quantities of fire and ſmoke, accompanied with an exploſion about once in five minutes. Some of theſe exploſions reſembled violent claps of thunder. The whole air was filled with ſmoaky particles and aſhes, which occaſioned much pain when they fell into the eye. At one time great ſtones were thrown up into the air, ſome of which were at leaſt as large as the hull of a ſhip's long boat. It firſt preſented a moſt magnificent ſight. The ſmoke, which rolled up, from time to time, in thick and heavy volumes, was coloured with all the various hues of yellow, orange, crimſon, and purple, which died away into a reddiſh grey and brown. As often as a new exploſion happened, the whole country, with its ſhaggy foreſts, were tinged with the ſame orange and purple, according to its diſtance, or particular expoſure to volcanic light. It ſometimes continued quite ſilent for five or ſix days together. It was remarked, that the exploſions of the volcanos recommenced after a ſhower of rain; ſo that it ſhould ſeem that rain excites them, by promoting or increaſing the fermentation of various mineral ſubſtances in the mountain. The black aſhes, with which the whole country was ſtrewed, were found to be long, needle like, and ſemi-tranſparent, and to contribute greatly to that luxuriance of vegetation, which is remarkable on this iſland; many plants here attaining twice the height which they reach in other countries. Their leaves are broader, their flowers larger, and more richly ſcented. Theſe iſlands in general are high and mountainous, abounding with wood and water, and the uſual productions of the tropical iſlands. The bread fruit, cocoa-nuts and plantains are not ſo good, nor ſo plentiful as at Otaheite; on the other hand, ſugar-canes and yams are not only in greater plenty, but of ſuperior quality, and much larger; ſome of the latter weighing fifty ſix pounds.

NEW CALEDONIA. — This iſland was called New Caledonia, by Captain Cook, in conſequence of his having diſcovered it in 1774, after many fruitleſs endeavours to learn from the natives the Indian name. Indeed, it is probable that it was not known by one general name, as it has been repreſented as the largeſt iſland that has been diſcovered in the Southern Pacific Ocean, New Zealand and New Holland excepted; extending from 19 deg. 37 min. to 22 deg. 30 min. ſouth latitude; and from 163 deg. 37 min. to 167 deg. 14 min. eaſt long. In length it is computed to be 87 leagues, in the direction of north-weſt and ſouth-eaſt; but its breadth no where exceeds 10. It is ſituated about 12 deg. diſtant from New Holland. The country is deſcribed as a ſpot diverſified by hills and vallies of various extent. From the hills iſſue many fine ſtreams, which render the vallies both fertile and pleaſant; and, but for which, the whole ſpot might be called a dreary waſte; nature having been leſs bountiful to New Caledonia than to the other tropical iſlands in the South Seas. The mountains, and other high parts, are, in general, incapable of cultivation, conſiſting chiefly of barren rocks. The whole coaſt appeared ſurrounded by reefs or ſhoals, which render the acceſs to it very dangerous. The inhabitants ſubſiſt chiefly on roots and fiſh. Plantains and ſugar canes are not plenty; bread fruit is very ſcarce, and the cocoa-nut trees are but thinly planted; but their yams and taras are in great abundance. Theſe people are of a pacific diſpoſition, and their women are far more chaſte than thoſe of the more eaſtern iſlands.

NEW ZEALAND. This country was firſt diſcovered by Taſman, the Dutch navigator, in the year 1642, who gave it the name of Staten Land, though it has been generally diſtinguiſhed, in our maps and charts, by the name of New Zealand, and was ſuppoſed to be part of a ſouthern continent; but it is now known, from the late diſcoveries of captain Cook, who ſailed round it in 1770, and found it to conſiſt of two large iſlands, divided by a paſſage (now called Cook's Straits) about four or five leagues broad, and lying nearly north and ſouth of each other, between the latitudes of 34 deg. 22 min. and 47 deg. 25 min. ſouth; and between the longitude of 166 and 180 deg. eaſt from Greenwich. The ſame navigator viſited it again in 1773; and, for the third time, in 1774. The two iſlands are nearly of the ſame extent, and, taken together, as large as Great Britain, having many ſmall iſlands about them. The northernmoſt is called, by the natives, Eahei-nomarve; and the ſouthernmoſt, Tovy, or Tovai-Poenammoo. The latter is moſtly hilly, and, to appearance, barren, and thinly inhabited: but the former, though very mountainous, is tolerably fertile, and can boaſt of a rivulet running through every valley. Though theſe vallies do not abound with wood, yet, from the apparent nature of the ſoil, it was the opinion of our ingenious and ſpeculative countryman, that every kind of European grain would flouriſh here; and that, through the exertion of induſtry in cultivation, not only the neceſſaries, but luxuries of life, might be obtained in rich variety. The climate, upon the whole, is ſaid to be more temperate than that of England, from the vegetables that were found growing there in the winter ſeaſon.

From the lateſt account it appears, that the vegetable productions of this country ſufficiently indicate the quality of the ſoil: indeed, the ſtrength in vegetation muſt be greatly aſſiſted by the temperature of the climate. The hills, except a few towards the ſea, are one continued foreſt of lofty trees, which flouriſh with uncommon vigour: and it was remarked, that no country abounded, upon the whole, ſo much with trees and plants, that were entirely unknown to the naturaliſts of Europe, as New Zealand. The ſize, growth, and durability of the timber, render it fit for any kind of building.

The only quadrupeds here are dogs and rats, both of which are eaten by the natives. Birds are very plentiful, and a perſon by remaining in one place, may ſhoot as many in a day as will ſerve for a meal for ſix. The country has been much enriched by Captain Cook, who introduced a variety of plants and European poultry, which he had the ſatisfaction on a reviſit to find greatly encreaſed. They have ſweet potatoes and yams, but nothing is raiſed by cultivation. The inhabitants are ſcattered along the coaſts in ſingle families or in larger tribes, and each in a ſtate of perpetual hoſtility with all the reſt. The unhappy ſubjects of conqueſt in theſe continental wars, fall victims to the ſavage rapacity of the conquerors, who glut themſelves with the inhuman banqueſt of the fleſh of their fellow creatures. Nor can this practice be wondered at among ſavages, as hunger amongſt civilized nations will abſorb every feeling; and he who has once learned to eat what he kills, will eaſily be induced to kill when he wants to eat. See the article CANNIBAL in the Alphabet.

NEW GUINEA, lies to the northward of New Holland, from which it is ſeparated by Endeavour Strait. The length of this ſtrait, from north-eaſt to ſouth-weſt, is ten leagues, and its breadth about five, except at the north-eaſt entrance, where it is contracted to ſomewhat leſs than two miles, by a congeries of iſlands, called Prince of Wales's Iſlands. Except this ſtrait, and the land of Cape Deliverance, the whole coaſt, and the circumjacent iſlands, ſeem to have been minutely examined both by the Dutch and Spaniards. Some traces of a paſſage, between New Holland and New Guinea, are alſo to be found in the accounts of former voyages; but Capt. Cook, in 1770, had the merit of eſtabliſhing the fact beyond diſpute. New Guinea was thus found to be a long narrow iſland, extending ſouth-eaſt from the equator to 12 S. lat. and from 131 to 153 E. lon. The land in general is very low, but covered with ſuch luxuriance of wood and herbage, as can ſcarcely be conceived. The nut-meg, cocoa-nut, bread fruit, and plantain-trees, beſides moſt of the trees, ſhrubs, and plants, that are common to the South-ſea iſlands, are found here in the greateſt perfection. The inhabitants make much the ſame appearance as the New Hollanders, and like them go naked.

NEW BRITAIN, is ſituated in the 4th degree of ſouth latitude, and 152 deg. 19 min. eaſt longitude from Greenwich. It was ſuppoſed to be part of an imaginary continent till captain Dampier found it to be an iſland, and ſailed through a ſtrait which divides it from New Guinea.

NEW IRELAND extends in length, from the north eaſt to the ſouth eaſt, about two hundred and ſeventy miles, but is in general very narrow. It abounds with a variety of trees and plants, and with many pigeons, parrots, rooks, and other birds. North weſtward of New Ireland a cluſter of iſlands was ſeen by captain Carteret, lying very near each other, and ſuppoſed to conſiſt of twenty or thirty in number. One of theſe, which is of very conſiderable extent, was named NEW HANOVER; but the reſt of the cluſter received the name of the ADMIRALTY ISLANDS.

EASTER ISLAND lies in the South Sea, and is of a triangular ſhape; it is about 10 or 12 leagues in circuit, has a hilly and ſtony ſurface, and an iron bound ſhore. The hills are of ſuch a height, as to be ſeen 15 or 16 leagues. No nation need contend for the honour of this diſcovery; for it affords neither ſafe anchorage, freſh water, nor wood for fuel. It is, however, the ſame that was ſeen by Davis in 1686; it was next viſited by Roggewein in 1722, and again by Capt. Cook in 1774. The country is naturally barren, and without wood; what little it yields muſt be raiſed by cultivation. Rats are the only quadrupeds, and birds there are but few. The ears of theſe people are long beyond proportion, and their bodies are ſcarcely any thing of the human figure. Lon. 109-46. W. lat. 27-5. S.

SANDWICH ISLANDS. — Theſe iſlands were diſcovered by Captain Cook in 1778, during the courſe of his laſt voyage to the Pacific Ocean, in order to ſearch for a north weſt paſſage, between the continents of Aſia and America. They form a magnificent groupe, and were among the laſt diſcoveries of Capt. Cook, who ſo named them in honour of the Earl of Sandwich, under whoſe adminiſtration theſe diſcoveries were made. They conſiſt of eleven iſlands, extending in latitude from 18-54. to 160 24 W. They are called by the natives, Owhyhee, Mowee, Ranai, Morotoi, Tahoorowa, Woahoo, Atooi, Neeheeheow, Oreehoua, Morotinne, and Tahoora, all inhabited except the two laſt. The climate of theſe iſlands differs very little from that of the Weſt Indies in the ſame latitude, though perhaps more temperate; and there are no traces of thoſe violent winds and hurricanes, which render the ſtormy months in the Weſt Indies ſo dreadful. There is alſo more rain at the Sandwich iſles, where the mountainous parts being generally enveloped in a cloud, ſucceſſive ſhowers fall in the inland parts, with fine weather, and a clear ſky, on the ſea-ſhore. Hence it is, that few of thoſe inconveniences, to which many tropical countries are ſubject, either from heat or moiſture, are experienced here. The winds, in the winter months, are generally from E. S. E. to N. E. The vegetable productions are nearly the ſame as thoſe of the other iſlands in this ocean; but the taro root is here of a ſuperior quality. The bread-fruit trees thrive not in ſuch abundance as in the rich plains of Otaheite, but produce double the quantity of fruit. The ſugar-canes are of a very unuſual ſize, ſome of them meaſuring eleven inches and a quarter in circumference, and having fourteen feet eatable. There is alſo a root of a brown colour, ſhaped like a yam, and from ſix to ten pounds in weight, the juice of which is very ſweet, of a pleaſant taſte, and is an excellent ſubſtitute for ſugar. The quadrupeds are confined to the three uſual ſorts, hogs, dogs, and rats. The fowls are alſo of the common ſort; and the birds are beautiful and numerous, though not various. Goats, pigs, and European ſeeds, were left by Capt. Cook; but the poſſeſſion of the goats ſoon gave riſe to a conteſt between two diſtricts, in which the breed was entirely deſtroyed. The food of the lower claſs conſiſts principally of fiſh and vegetables, to which the people of higher rank add the fleſh of dogs and hogs. Their idle hours are filled up with various amuſements, ſuch as dancing, boxing, wreſtling, &c. As the iſlands are not united under one ſovereign, wars are frequent among them, which, no doubt, contribute greatly to reduce the number of inhabitants, which, according to the proportion aſſigned to each iſland, does not exceed 400,000. The ſame ſyſtem of ſubordination prevails here as at the other iſlands, the ſame abſolute authority on the part of the chiefs and the ſame unreſiſting ſubmiſſion on the part of the people. The government is likewiſe monarchical and hereditary. At Owhyee there is a regular ſociety of prieſts living by themſelves, and diſtinct in all reſpects from the reſt of the people. Human ſacrifices are here frequent; not only at the commencement of a war, or any ſignal enterprize, but the death of every conſiderable chief, calls for a repetition of theſe horrid rites, which are nearly the ſame as thoſe practiſed at Otaheite, and other iſlands in the South Seas. For a particular deſcription of this barbarous ceremony, ſee the article EATOOA, in the Alphabetical Arrangement.

Notwithſtanding the irreparable loſs in the death of Capt. Cook, who was here murdered through ſudden reſentment and violence, they are acknowledged to be of the moſt mild and affectionate diſpoſition. They live in the utmoſt harmony and friendſhip with each other; and in hoſpitality to ſtrangers they are not exceeded even by the inhabitants of the Friendly Iſlands. Their natural capacity ſeems, in no reſpect, below the common ſtandard of mankind; and their improvements in agriculture, and the perfection of their manufactures, are certainly adequate to the circumſtances of their ſituation, and the natural advantages which they enjoy.

KING GEORGE's SOUND, an iſland ſo named by Capt. Cook; but by the natives it is called Nootka. Upon the ſea-coaſt, the land is tolerably high and level; but, within the Sound, it riſes into ſteep hills, which have an uniform appearance. The trees, of which the woods are compoſed, are the Canadian pine, white cypreſs, and two or three other ſorts of pine. In general, the trees grow here with great vigour, and are of a large ſize. About the rocks and borders of the woods, were ſeen ſome ſtrawberry plants and raſberry, currant, and gooſeberry buſhes, and in a flouriſhing ſtate. The principal animals ſeen here were racoons, martins, and ſquirrels. Birds are far from being numerous. Their bodies are always covered with red paint, but their faces are ornamented with variety of colours, a black, a bright red, or a white colour; the laſt of which gives them a ghaſtly and horrible appearance. They appear to be docile, courteous, and good-natured; but they are quick in reſenting injuries, and, like moſt other paſſionate people, as quickly forgetting them. A rattle and a ſmall whiſtle are the only inſtruments of muſic that were ſeen among them. Their houſes conſiſt of very long broad planks, reſting upon the edges of each other, tied, in different parts, with wiſhes of pine-bark. The furniture of their houſes conſiſts principally of cheſts and boxes of various ſizes, piled upon each other, at the ſides or ends of their houſes, in which are depoſited their garments, and whatever they deem valuable. They have alſo ſquare and oblong pails, bowls to eat their food out of, &c. The irregularity and confuſion of their houſes is far exceeded by their naſtineſs and ſtench. They not only dry their fiſh within doors, but they alſo gut them there; which, together with their bones and fragments, thrown upon the ground at meals, occaſions ſeveral heaps of filth, which are never removed, till it becomes troubleſome, from their bulk, to paſs over them. Every thing about the houſe ſtinks of train-oil, fiſh, and ſmoke; and every part of it is as filthy as can be imagined. Lon. 233·12. E. lat. 49·33. N.

PRINCE WILLIAM's SOUND. This inlet on the coaſt, diſtinguiſhed by Captain Cook under the name of Prince William's Sound, is ſituated to the northward of King George's Sound, in long. 215·21 E. lat. 59·33 N. The perſons and dreſs of the natives much reſemble thoſe of King George's Sound, but they are by no means ſo filthy in their cuſtoms and manners; the productions are nearly the ſame kind, excepting that they abound more in animals which produce furs, ſuch as bears, common and pine martins, ſea otters, ſeals, racoons, ſmall ermines, foxes, and the whiteſt cats, or lynx, and a variety of others. In conſequence of the abundance of furs this place produced, a trade has been eſtabliſhed by the ſome of the Britiſh merchants; who ſend trinkets and utenſils to this place, exchange them for furs, and convey them to China, where they have a quick and profitable ſale for them. An extenſive river flows here, and runs many miles up the country. Captain Cook called it after his own name.

NORTON's SOUND. This inlet to which Captain Cook gave the name of Norton's Sound, in honour of Sir Fletcher Norton, afterwards Lord Grantley, lies between the lat. of 64° and 65° north. It was the opinion of Captain Cook, that this peninſula had been an iſland at ſome diſtant, for there were marks of the ſea, having formerly flowed over the iſthmus; and even at preſent it appeared to be kept out by a bank of ſand, ſtones, and wood, which the waves had thrown up.

He alſo diſcovered Sandwich Sound, proceeded and ſtill continued to trace the American Coaſt, till he diſcovered the ſtrait which ſeparates it from the continent of Aſia. They paſſed the ſtrait, and arrived on the 20th of Auguſt 1778, in lat. 70 deg. 54 min. long. 194 deg. 55 min. where they found themſelves almoſt ſurrounded with ice, and the farther they proceeded to the eaſtward, the cloſer the ice became compacted. They continued labouring among the ice till the 25th, when a ſtorm came on, which made it dangerous for them to proceed; and a conſultation was therefore held on board the Reſolution, as ſoon as the violence of the gale abated, when it was reſolved, that as this paſſage was impracticable for any uſeful purpoſe of navigation, which was the great object of the voyage, it ſhould be proſecuted no farther; and eſpecially on account of the condition the ſhips were in, the approach of winter, and their great diſtance from any known place of refreſhment. The voyage indeed afforded ſufficient evidence, that no practicable paſſage exiſts between the Atlantic and Pacific Oceans towards the north; and this voyage alſo aſcertained the weſtern boundaries of the great continent of America.

Captain Cook thought it now high time to quit theſe northerly regions, and retire to ſome place for the winter, where he might obtain proviſions and refreſhments. He did not conſider Petropaulowſka, or the harbour of St. Peter and St. Paul, in Kamtſchatka, as likely to furniſh a ſufficient ſupply. He had likewiſe other reaſons for not going thither at preſent; the principal of which was his great unwillingneſs to remain inactive for ſix or ſeven months, which would have been the conſequence of paſſing the winter in any of theſe northern countries. He at length concluded that no ſituation was ſo convenient as the Sandwich Iſlands. To them, therefore, he formed a reſolution of repairing. But a ſupply of water being neceſſary before he could execute that deſign, he determined, with a view of procuring this eſſential article, to ſearch the coaſt of America for a harbour, by proceeding along it to the ſouthward.

When he arrived at the Sandwich iſlands and anchored in Karakakooa Bay, to his great diſappointment, inſtead of meeting with that hoſpitable reception he had before experienced, he found the natives diſpoſed to hoſtility, and unwilling to furniſh thoſe ſupplies they had ſo liberally contributed on his firſt viſit. The cauſe of this ſudden change of behaviour in the natives is not accounted for in any of the narratives of the voyage; but we are credibly informed that it originated from ſome of the common ſailors, having diſturbed the Morais, or places of burial, which they hold of the moſt ſacred nature. After a variety of ſkirmiſhes between our people and the natives, one of the ſhip's boats was ſtolen, Captain Cook was therefore determined on its reſtitution; to effect which, according to his uſual practice, he endeavoured to get the king on board, in order to detain him as an hoſtage till the boat was returned. The king was willing to go on board, but the natives, from an attachment of zeal and loyalty, would not permit him to depart. This occaſioned ſeveral affrays, in one of which a chief was ſlain; at length, in purſuing the attempt, Capt. Cook, with many of the crew, fell victims to the fury of the natives. This dreadful cataſtrophe did not go unrevenged; the natives, through the ſuperior force of arms, were brought to ſubjection, and ſued for peace, which was granted upon condition of bringing back the body of Capt. Cook; the mangled remains of which being produced, together with a number of preſents and many conceſſions, peace was reſtored previous to the departure of our people from the iſland.

Thus ended the life of the greateſt navigator that this or any other nation ever could boaſt, after having ſucceſsfully led his crews of gallant Britiſh ſeamen thrice round the world. We ſhall now turn from this calamitous ſcene, and endeavour to pay a juſt tribute to the memory of our celebrated navigator, in a ſhort ſketch of his character.

Captain James Cook raiſed himſelf ſolely by his merit from a very obſcure birth to the rank of Poſt Captain in the Royal Navy. He poſſeſſed, in an eminent degree, all the qualifications requiſite for his profeſſion and great undertakings. Deliberate in judging; ſagacious in determining; active in executing; unſubdued by labour, difficulties and diſappointments; fertile in expedients, never wanting preſence of mind, but ever poſſeſſing the full uſe of a ſound underſtanding. In diſcipline, though mild and juſt, he was exact: he was a father to his people, who were attached to him from affection, and obedient from confidence. That ſpirit of humanity and juſtice with which he treated the ſavages wherever he found them, when oppoſed to the ferocious and inhuman conduct of the firſt conquerors in the New World, does honour to his age and country, and will hand him down with reverence to poſterity.

We cannot conclude without remarking that no ſcience ever received greater additions from the labours of a ſingle man, than Geography has done from thoſe of Captain Cook. In his firſt voyage to the South Seas, he diſcovered the Society Iſlands; determined the inſularity of New Zealand; diſcovered the ſtraits which ſeparate the two iſlands, and are called after his name; and made a complete ſurvey of both. He afterwards explored the Eaſtern coaſt of New Holland, hitherto unknown; an extent of twenty-ſeven degrees of latitude, or upwards of two thouſand miles. In his ſecond expedition, he reſolved the great problem of a ſouthern continent, having traverſed that hemiſphere between the latitude of 40° and 70°, in ſuch a manner as not to leave a poſſibility of its exiſtence, unleſs near the Pole, and out of the reach of navigation. During this voyage, he diſcovered New Caledonia, the largeſt iſland in the Southern Pacific Ocean, except New Zealand; the iſland of Georgia; and an unknown coaſt, which he named Sandwich Sound, the Thule of the Southern hemiſphere; and having twice viſited the tropical ſeas, he ſettled the ſituations of the old, and made ſeveral new diſcoveries. But the laſt voyage is diſtinguiſhed above all the reſt, by the extent and importance of its diſcoveries. Beſides ſeveral ſmaller iſlands in the Southern Pacific, he diſcovered, to the North of the Equinoctial Line, the group called the Sandwich Iſlands, which, from their ſituation and productions, bid fairer for becoming an object of conſequence in the ſyſtem of European navigation, than any other diſcovery in the South Sea. He afterwards explored what had hitherto remained unknown of the Weſtern coaſt of America from the latitude of 43° to 70° North, containing an extent of three thouſand and five hundred miles; aſcertaining the proximity of the two great continents of Aſia and America; paſſed the ſtraits between them, and ſurveyed the coaſt on each ſide, to ſuch a height of northern latitude, as to demonſtrate the impracticability of a paſſage, in that hemiſphere, from the Atlantic into the Pacific Ocean, either by an Eaſtern or a Weſtern courſe. In ſhort, if we except the Sea of Amur, and the Japaneſe Archipelago, which ſtill remain imperfectly known to Europeans, he has completed the hydrography of the habitable globe.

PELEW ISLANDS.

That chain of iſlands called the PALOS, or PELEW ISLANDS, ſituated in the weſt part of the Pacific Ocean, between the 5th and 9th degrees of north latitude, and between 130 and 136 degrees of eaſt longitude, though heretofore imperfectly noticed by ſome ſhips making the eaſtern paſſage from China, were never viſited by any Europeans, till the crew of the Antelope, captain Wilſon, a packet belonging to the Eaſt India Company, which was wrecked in Auguſt 1783, landed there, and were the means of diſcovering to us, a new world, or ſet of human beings, who, though of an uncultivated nature, appeared to be greatly different from thoſe commonly termed ſavages, and evinced principles of humanity and generoſity, that would reflect the higheſt honour on the moſt exalted of our race. A very ſingular circumſtance much facilitated the intercourſe between our countrymen and the natives. A Malay, who ſometime before was caſt away upon this iſland, had acquired the language; and it happened that one of the Antelope's men was a native of Bengal, and ſpoke the Malay tongue, by which means a ready communication was maintained on both ſides. Theſe people were entirely naked. They were of a deep copper colour, and their ſkins ſoft and gloſſy, owing to the external uſe of cocoa nut oil. Each chief had a baſket of beetle nut, and a bamboo, finely poliſhed, and inlaid at each end, in which they carried a kind of coral, burnt to a lime, called *chinam*. It was obſerved that all their teeth were black, and that the beetle nut, of which they had always a quid in their mouths, rendered the ſaliva red, which together with their black teeth, gave their mouths a very diſguſting appearance. They were of a middling ſtature, ſtrait, and muſcular, their limbs well formed, and they had a majeſtic gait. Their hair was black, long, and rolled up behind cloſe to their heads, which appeared neat and becoming. They tatooed their legs a little above the ancles to the middle of their thighs, which gave them a deeper colour than the other parts of their bodies. The principal women and particularly the wives of the Rupacks or great officers of ſtate, were rather fairer than the reſt of their ſex, had little ornaments about them, and their faces and breaſts were rubbed over with turmeric.

Whatever ſurprize the ſingularity of theſe natives might excite in the minds of our people, the natives were no leſs wrapt in admiration at their appearance. The whiteneſs of colour attracted them ſo much, that it was evident they had never before ſeen any Europeans. They were continually exclaiming, *weel, weel!* and *weel-a-trecoy*; words which implied that they were perfectly pleaſed with their viſitors. They ſtroked their bodies and arms outſide the garments, ſeeming to doubt whether their coverings were not a part of their real body, being totally ignorant of the uſe of cloaths. The hands of the Europeans next engaged their attention, and particularly the black veins of the wriſts. They probably imagined the whiteneſs of the hands and face to be artificial; and the blackneſs of the veins cauſed them to think, that it was a mode of tatooing; for they deſired to look at the top parts of the arms, and to ſee if the whiteneſs was continued. As the natives expreſſed a deſire that captain Wilſon would ſend one of his people to Pelew, that the king might ſee what kind of beings white men were, the captain complied, and appointed his brother for that purpoſe, giving him a ſmall remnant of blue cloth, a canniſter of tea, another of ſugar-candy, and a jar of preſerved fruit, as a preſent for the king. The natives behaved in the moſt friendly manner to the Engliſh; and their monarch ſoon after paid them a viſit, with his ſon and brother. His majeſty was perfectly naked, and had no kind of ornament or mark of diſtinction, like his principal officers, who wore a bracelet of bone at their wriſts. He bore a hatchet on his ſhoulder, the head of which was made of iron, a circumſtance which ſurprized our people much, as all the other hatchets they had ſeen were of ſhell. The handle of it, which formed a ſharp angle, ſtuck cloſe to his ſhoulder, lying before and behind, and wanting no tying to keep it ſteady in walking.

Captain Wilſon availed himſelf of this opportunity to obtain permiſſion from the king to build a veſſel, in order to convey the crew to ſome European ſettlement; and highly gratified him by cauſing a party of men to be drawn up, and fire three vollies. This occaſioned ſuch hooting and chattering, as equalled in noiſe the report of the pieces. Captain Wilſon dreſſed the king in a ſilk coat and blue trowſers. He was extremely well made, but had loſt his noſe, whether in battle, or from a ſcrophulous diſeaſe, which is prevalent there, was not known. Arra Kooker, one of the king's brothers, requeſted a white ſhirt, and as ſoon as it was given him, he put it on, in tranſports of joy, which he indicated by dancing and jumping, and in forming a humourous contraſt between his ſhirt and his ſkin. This prince had a great propenſity to mimicry, and often amuſed our people by taking off their manners, but with ſo much good nature, that no one could feel the leaſt offence. He entertained a great partiality for their Newfoundland dog, which he often fed; till at length the creature felt a partiality for him, and, at his appearance, would jump, bark, leap, and play a variety of tricks. Arra Kooker would often imitate him in the ſame mode of ſalutation, by barking, jumping, &c. which could not fail of exciting the riſible faculties. This prince was ſeemingly about forty years of age, ſhort in ſtature, but ſo plump and fat, that he was almoſt as broad as he was long. After various ceremonies had paſſed, the captain preſented his majeſty with a ſcarlet coat; who then making ſigns to go on ſhore, jumped into the water, and ſwam to land.

The employment of the men ſeemed to be that of gathering cocoa-nuts, felling trees, and making ſpears and darts, the chief warlike inſtruments of the Pelewans. In the uſe of theſe they were remarkably expert, as they afforded abundant proof in divers engagements with the ſubjects of a neighbouring prince; in which they were aided by a ſelect party of the Engliſh at the requeſt of Abba Thulle, and obtained a compleat victory by dint of the ſuperior force of our fire arms. As the Engliſh had been uſeful in their aſſiſtance againſt the enemy, the king was deliberating what preſent or compenſation he ſhould make to the Engliſh leader. After a while he ſent him, as a particular mark of his gratitude and eſteem, two lovely young women. Captain Wilſon, who was a grave ſober man, and had his ſon with him, a youth about ſeventeen, was particularly embarraſſed. He, however, thought proper to ſend them back again; the king of Pelew was exceedingly unhappy that his preſent was not accepted, and concluded, in his own mind, that their being rejected was owing to their not being ſufficiently young. To obviate this objection, after ſome ſtrong parental ſtruggles, he actually ſent captain Wilſon his own daughter, a ſweet little girl, who was no more than twelve years old. She was of courſe returned alſo; but it was extremely difficult to ſatisfy the king that in this rejection of his preſents no inſult was intended. We cannot omit mentioning at the cloſe of this account, that a ſhort time before the departure of our people, the king of Pelew requeſted captain Wilſon to take with him his ſecond ſon, whoſe name was Lee Boo, to England, expreſſing a patriotic hope that he would acquire many things which, at his return, would greatly benefit his native country. This youth, who added to an active and penetrating mind, the moſt ingenuous and endearing manners, was treated with the greateſt care and attention by captain Wilſon, and was advancing rapidly in a knowledge of the Engliſh language, and of writing, when he fell a victim to the ſmall pox, at the age of 20 years.

In the extremity of his laſt illneſs he made uſe of theſe words to a perſon who came over with him. “When you go to Pelew,
“ tell Abba Thulle that his ſon take much drink to make
“ ſmall-pox go away, but he die;—that the captain and mother
“ (meaning Mrs. Wilſon) very kind;—all Engliſh very good
“ men;—was much ſorry I could not ſpeak to the king my fa-
“ ther the number of fine things the Engliſh had got.” He was buried in Rotherhithe church, where a tomb was erected to his memory by the Eaſt-India Company.

GEOGRAPHY.

NEW HOLLAND is the largeſt known land that does not bear the name of a continent; it extends from latitude 43-42. South, to within 10-30. of the equator; and from 110-30. to 153-30. E. long. ſo that its ſquare ſurface conſiderably exceeds that of Europe. When this vaſt iſland was firſt diſcovered is uncertain: towards the beginning of the laſt century, the north and weſt coaſts were traced by the Dutch; the ſouthern extremity was diſcovered by Taſman in 1642; in 1770, Capt. Cook explored the eaſt and north-eaſt ſide, from 38. S. and aſcertained its ſeparation from New Guinea; and in 1773, Capt. Furneaux, by connecting Taſman's diſcoveries with Capt. Cook's, compleated the circuit. In that part of it, which Taſman diſtinguiſhed by the name of Van Diemen's Land, and which was viſited by Capt. Furneaux in 1773, and again by Capt. Cook in 1777.

New Holland, in general, is diverſified with hills and vallies, and every where of a greeniſh hue; the ſides of the hills are covered with large trees, and plenty of water falls from the rocks in beautiful caſcades, two or three hundred feet perpendicular, into the ſea; but, in the interior parts, it bears marks of being a very dry country. The ſoil, in ſome places, is black and rich, though thin; and, in others, it is either ſandy, or conſiſts of a yellowiſh mould. The foreſt trees grow to a great height, and in general quite ſtraight, branching but little till towards the top. The only quadruped, beſides the kanguroo, is a ſort of opoſſum, about twice the ſize of a large rat. Birds are neither ſo numerous, nor in ſuch variety, as in the more northern parts: the ſea is ſtored with its uſual plenty, and the rocks with muſſels and other ſhell-fiſh. They have neither houſes, canoes, vegetable productions, nor any method of catching large fiſh; their habitations are the trunks of trees hollowed by fire; and their food ſhell-fiſh, birds, and the kanguroo. Of their method of hunting no idea can be formed, the only weapon that was ſeen among them being a ſhort pointed ſtick, in the uſe of which they ſhewed no dexterity: they have little of that wild or fierce appearance, common to people in their ſituation; on the contrary, they are mild and cheerful, without reſerve or jealouſy of ſtrangers; the number of inhabitants appears to be very ſmall, in proportion to the extent of the country.

It is ſtrange to remark that both ſexes in this country go ſtark naked, and ſeem to have no more ſenſe of indecency in diſcovering their whole body, than the inhabitants of England have in the diſcovery of their hands and face. In ſhort, in point of intellectual faculties, or obſervations of what the poliſhed part of mankind call the laws of decorum, they ſeemed as deficient as the brutal creation.

VAN DIEMEN's LAND. The inhabitants of Van Diemen's Land are from the ſame ſtock with thoſe of the northern parts of New Holland: tho' the account of thoſe met with by Capt. Cook on the eaſt, ſhews that they differ in many reſpects; yet, upon the whole, it muſt be allowed, that diſtance of place, entire ſeparation, diverſity of climate, and length of time, all concurring to operate, will account for greater differences, both as to their perſons, manners, and cuſtoms, than really exiſt between the natives of Van Diemen's Land, and thoſe of Botany Bay, deſcribed in Captain Cook's firſt voyage to this iſland. The author of the narrative of the late expedition to New Holland, remarks, that, to the geographical knowledge of this country, ſupplied by Captain Cook, and Captain Furneaux, the adventurers were able to add nothing. The latter explored the coaſt from Van Diemen's Land to the latitude of 39 deg. ſouth; and Capt. Cook from Point Hicks, which lies 37 deg. 58 min. to Endeavour Straits. The intermediate ſpace between the end of Furneaux's diſcovery and Point Hicks, is, therefore, the only part of the ſouth-eaſt coaſt unknown.

BOTANY BAY, ſo called by Captain Cook, who diſcovered it from the great number of plants collected at this place, is ſituated on the eaſtern coaſt of New Holland, denominated, by that celebrated navigator, New South Wales, in the latitude of 34 deg. ſouth longitude, 208 deg. 37 min. weſt. The climate is very deſirable to live in. In ſummer the heats are uſually moderated by the ſea breeze, which ſets in early; and in winter the degree of cold is ſo ſlight, as to occaſion no inconvenience.

Botany Bay was the ſpot deſtined for the planting a new colony in this part of the globe, the fleet, therefore fitted out by government for the expedition, ſailed from England in March, 1787; reached and anchored in the bay on the 20th of January, 1788, after a paſſage of thirty-ſix weeks, in which a moſt arduous undertaking was effected, with more ſucceſs, and leſs loſs, than hardly ever afforded a fleet in ſuch a predicament. Previous to the ſettlement on the ſpot under immediate conſideration, an expedition up the bay was deemed expedient, in order to explore the nature of the country, and ſelect a place for carrying into execution their plan and deſign. None being diſcovered that appeared very convenient for the purpoſe, the governor and the lieutenant-governor proceeded in a boat to examine an opening, to which Captain Cook had given the name of Port Jackſon, preſuming that good anchorage might be found within it. Nor did they ſearch in vain; for ſuch was their account of the harbour, and the advantages attending the place, upon their return, that a reſolution was formed of evacuating Botany Bay. According to the account of thoſe who have formed the new ſettlement at Port Jackſon, they are utterly ſtrangers to the cultivation of the ground, and wholly depend for food on the few fruits they gather; the roots they dig up in the ſwamps; and the fiſh they pick up along ſhore, or contrive to ſtrike from their canoes with ſpears. Fiſhing, indeed, ſeems to engroſs nearly the whole of their time, probably from its forming the chief part of a ſubſiſtence, which, obſervation has proved, nothing ſhort of the moſt painful labour, and unwearied aſſiduity, can procure.

PORT JACKSON.

The paſſage from Botany Bay, to Port Jackſon, was both ſpeedy and pleaſant. Having paſſed between the capes which form its entrance, the fleet arrived in a port ſuperior, in extent and excellence, to all that had been obſerved before. During a run up the harbour of about four miles, in a weſternly direction, a luxuriant proſpect preſented itſelf on the ſhores, covered with trees to the water's edge, among which many of the Indians were frequently ſeen, till the fleet arrived at a ſmall ſnug cove to the ſouthward, on the banks of which the plan of operations was deſtined to commence. The neceſſary previous buſineſs having been tranſacted; upon an appointed day, the commiſſions were read, and poſſeſſion was taken of the ſettlement in form. The marine battalion being drawn up, and the convicts aſſembled on the occaſion, his Majeſty's commiſſion was read, appointing his Excellency Arthur Phillip, eſq. Governor and Captain General in and over the territory of New South Wales, and its dependencies; together with the acts of parliament for eſtabliſhing trials by law within the ſame: and the patents under the great ſeal of Great Britain, for holding civil and criminal courts of judicature, by which all caſes of life and death, as well as matters of property, were to be decided. The extent of this authority is defined in the governor's commiſſion, to reach from the latitude of 43 deg. 49 min. ſouth, to the latitude of 10 deg. 37 min. ſouth, being the northern and ſouthern extremities of New Holland. It commences again at the 135th degree of longitude eaſt, and proceeding in an eaſternly direction, comprehends all iſlands within the limits of the above ſpecified latitudes in the Pacific Ocean. As the diſcoveries of Engliſh navigators alone are compriſed in this territory, it is preſumed this partition will obviate all cauſe of future litigation between us and the Dutch. Perſons induced to emigrate hither, are recommended, before they quit England, to provide all their wearing apparel for themſelves, family and ſervants; their furniture, tools of every kind, and implements of huſbandry, (among which a plough need not be included, the hoe being uſed,) as they will touch at no place where theſe articles can be purchaſed to advantage. If the ſheep and hogs are Engliſh alſo it will be the better. With reſpect to wines, ſpirits, tobacco, ſugar, coffee, tea, rice, and many other articles, they may venture to rely on Teneriffe, or Madeira, the Brazils, and Cape of Good Hope. It will not be their intereſt to draw bills on their voyage out, as the exchange of money will be found invariably againſt them, and a large diſcount alſo deducted. Drafts on the places they are to touch at, or caſh, (dollars if poſſible,) will beſt anſwer their purpoſe.

In order to render this Syſtem as uſeful and conciſe as poſſible, I have introduced a variety of Tables, exhibiting the extent, boundaries, diviſions, ſubdiviſions, chief towns, &c. of each country, kingdom, and province, in one point of view; by which means I have been enabled to comprize, in this limited ſpace, the fundamental principles of Geography: and as this conciſe plan has never been adopted in any Dictionary of Arts and Sciences before, I preſume it will be conſidered as an addition of an important nature. To render this Syſtem ſtill more valuable, the Readers will be preſented, excluſive of the General Map of the World, with accurate and comprehenſive whole ſheet Maps of Europe, Aſia, Africa, North America, and South America.

The manners, cuſtoms, laws, &c. of the inhabitants of the ſeveral countries are mere hiſtorical matters, and therefore purpoſely omitted as they do not, ſtrictly ſpeaking, belong to Geography; but ſuch narratives as ſerve to illuſtrate the detached alphabetical parts, have already been introduced in the work, and will alſo be noticed as they hereafter occur, ſince their inſertion tends to explain many circumſtances, both intereſting and entertaining.

Thoſe who wiſh to be acquainted with theſe particulars, are referred to Bankes's Syſtem of Geography, containing the whole of Cook's voyages, where, independent of the geographical deſcriptions, are introduced copious narratives, including very minute accounts of his various interviews with the natives of the different regions he diſcovered; together with extracts from all the works of a ſimilar nature that have been publiſhed from the death of that illuſtrious navigator to the preſent time.

As the uſe of the celeſtial GLOBE *was omitted in Aſtronomy, I deemed it more eligible to omit that of the terreſtrial in this Syſtem, in order to bring them into one point of view: I ſhall therefore give them both under the article* GLOBE *in the order of the alphabet, and further, under that head I ſhall alſo introduce ſome mathematical problems, tending to illuſtrate the terreſtrial Globe, and other eſſential matters in geography.*

As the New Diſcoveries have ſo univerſally excited the public curioſity, and particularly the New Settlement formed at Port Jackſon in New Holland; I have been induced to treat more copiouſly on thoſe particulars than on the other parts of the Syſtem; and, in order to gratify the ſpeculative enquirer, have related many circumſtances highly intereſting, which, though not ſtrictly geographical, will, I preſume, from their importance, and the entertainment they will afford the Readers in general, ſufficiently apologize for their introduction.

SYSTEM OF GEOMETRY.

HISTORY OF GEOMETRY.

GEOMETRY, the ſcience, or doctrine of extenſion, or extended things; that is, of lines, ſurfaces, or ſolids. The word is Greek, γεωμετρεα, formed of γεα, or γη, *earth*; and μετρεω, *meaſure*; it being the neceſſity of meaſuring the earth, and the parts and places thereof, that gave the firſt occaſion to the invention of the principles and rules of this art, which has ſince been extended and applied to numerous other things; inſomuch that *geometry* with arithmetic, is now the general foundation of all mathematics. Herodotus, Diodorus and Strabo, aſſert that the Egyptians were the firſt inventors of *geometry*; and that the annual inundations of the Nile were the occaſion of it; for that river bearing away all the bounds and land-marks of men's eſtates, and covering the whole face of the country, the people, ſay they, were obliged to diſtinguiſh their lands by the conſideration of their figure and quantity; and thus, by experience and habit, formed themſelves a method, or art, which was the origin of *geometry*. Joſephus attributes the invention to the Hebrews. From Egypt *geometry* paſſed into Greece, where it was much cultivated and improved by Thales, Pythagoras, Anaxagoras of Clazomene, Hippocrates of Chios, and Plato, who teſtified his conviction of the neceſſity and importance of *geometry*, in order to the ſucceſsful ſtudy of philoſophy by the following inſcription on the door of his academy, ȣδεις αγεωμέτρητος εισειτω, *let no one ignorant of geometry enter here.* About fifty years after Plato, lived Euclid, who collected together all thoſe theorems which had been invented by his predeceſſors in Egypt and Greece, and digeſted them into fifteen books, entitled the **Elements** of *Geometry*; and thoſe propoſitions which were not ſatisfactorily proved, he more accurately demonſtrated. The next to Euclid of thoſe ancient writers, whoſe works are extant, is Apollonius, Pergæus, who flouriſhed in the time of Ptolemy Euergetes, about two hundred and thirty years before Chriſt, and about a hundred years after Euclid. The third ancient geometer, whoſe writings remain, is Archimedes of Syracuſe, who was famous about ten years after Apollonius.

We can only mention Eudoxus of Cnidus, Archylas of Tarentum, Philolaus, Eratoſthenes, Ariſtarchus of Samos, Dinoſtratus, the inventor of the Quadratrix, Menechmus, his brother and the diſciple of Plato, the two Ariſteus's, Conon, Thraſideus, Nicoteles, Leon, Theudius, Hermotimus, and Nicomedes, the inventor of the Conchoid; beſides whom, there are many other ancient geometers, to whom this ſcience is indebted. The Greeks continued their attention to *geometry*, even after they were ſubdued by the Romans. But the Romans themſelves were ſo little acquainted with this ſcience, even in the moſt flouriſhing time of their republic, that they gave the name of mathematicians, as Tacitus informs us, to thoſe who purſued the chimeras of divination and judiciary aſtrology. Among the Greeks we find many excellent geometers ſince the commencement of the Chriſtian æra, and after the tranſlation of the Roman empire. Ptolemy lived under Marcus Aurelius; and we have extant the works of Pappus of Alexandria who lived in the time of Theodoſius; the commentary of Eutocius, the Aſcalonite, who lived about the year of Chriſt 540, on Archimedes's menſuration of a circle; and the commentary on Euclid, by Pappus, who lived under the empire of Anaſtaſius. The conſequent inundation of ignorance and barbariſm was unfavourable to *geometry* as well as the other ſciences; and thoſe few who applied themſelves to this ſcience, &c. were calumninated as magicians. However, in theſe times of European darkneſs, the Arabians were diſtinguiſhed as the guardians and promoters of ſcience; and from the ninth to the fourteenth century they produced many aſtronomers, geometers, geographers, &c. At the revival of letters, there was ſcarcely one European capable of tranſlating and commenting on the works of the ancient geometers; and *geometry* made little progreſs till the time of Des Cartes, who publiſhed his *Geometry* in 1637. However, in 1635, Bonaventure Cavalerius, an Italian of the order of Jeſuits, publiſhed his *Geometry of Indiviſibles*; Gregory St. Vincent, in 1647, publiſhed his treatiſe, intitled Quadratura Circuli & Hyperbolæ, a work abounding with excellent theorems and paralogiſms; and Paſcal, about the ſame time, publiſhed his treatiſe of the Cycloid. Geometry, as far as it was capable of deriving aid and improvement from the arithmetic of infinites, was indebted to the labours of Fermat, Barrow, Wallis, Mercator, Brounker, J. Gregory, Huygens, and others; to whom we may add Newton and Leibnitz. See **Fluxions**.

But Sir Iſaac Newton contributed to the progreſs of pure geometry by his two treatiſes *De Quadratura Curvarum*, and *Enumeratio Linearum Tertii Ordinis*; and ſtill farther by his incomparable and immortal work, intitled *Philoſophiæ Naturalis Principia Mathematica*, which will always be conſidered as the moſt extenſive and ſucceſsful application of *geometry* to phyſics. We cannot forbear tranſcribing in this place the compliment paid to this author by the editors of the French *Encyclopedie*, who, conſidering the various monuments of the author's genius, and that he had made his principal diſcovery before the age of twenty-four, are tempted, they ſay, to ſubſcribe the words of Pope, that the ſagacity of Newton aſtoniſhes even celeſtial intelligencies, and that they contemplate him as a being occupying a kind of middle ſtation between man and themſelves; or at leaſt they cannot forbear exclaiming, *homo homini quid præſtat!* what a diſtance does there ſubſiſt between one man and another! The modern geometers are innumerable; and the names of Cotes, Maclaurin, Simpſon, Emerſon, &c. will always be held in eſteem and veneration by thoſe that are devoted to the ſtudy of *geometry* and mathematics. The province of *geometry* is almoſt infinite: few of our ideas but may be repreſented to the imagination by lines, upon which they become of *geometrical* conſideration; it being *geometry* alone that makes compariſons, and finds the relations of lines. Aſtronomy, muſic, mechanics, and, in a word, all the ſciences which conſider things ſuſceptible of more or leſs, i. e. all the preciſe and accurate ſciences may be referred to *geometry*; for all ſpeculative truths conſiſting only in the relations of things, and in the relations between thoſe relatious, they may be all referred to lines. Conſequences may be drawn from them; and theſe conſequences, again, being rendered ſenſible by lines, they become permanent objects, which may be conſtantly expoſed to a rigorous attention and examination: and thus we have infinite opportunities both of enquiring into their certainty, and purſuing them farther.

Geometrical lines and figures are not only proper to repreſent to the imagination the relations between magnitudes or between things ſuſceptible of more and leſs; as ſpaces, times, weights, motions, &c. but they may even repreſent things which the mind can no otherwiſe conceive, e. gr. the relations of incommenſurable magnitudes.

The ancient *geometry* was confined to very narrow bounds, in compariſon of the modern. It only extended to right lines and curves of the firſt order, or conic ſections; whereas into the modern *geometry* new lines of infinitely more and higher orders are introduced. *Geometry*, is diſtinguiſhed into *theoretical* or *ſpeculative*, and *practical*. The firſt contemplates the properties of continuity; and demonſtrates the truth of general propoſitions, called **Theorems**. The ſecond applies thoſe ſpeculations and theorems to particular uſes in the ſolution of problems. It is the firſt of theſe that we ſhall chiefly inſiſt upon in this place, referring for the other to menſuration, and gauging, ſurveying, trigonometry, navigation, and ſuch other ſciences as have their dependence thereon.

Theoretical **Geometry** is diſtinguiſhed into *elementary* and *ſublime*.

Elementary or *Common* **Geometry**, is employed in the conſideration of right lines, and plain ſurfaces, and ſolids generated therefrom.

The Higher or Sublime **Geometry** is employed in the conſideration of conic ſections, curve lines, &c.

PART I. SECT. I.

OF LINES, ANGLES, &c.

Definitions. 1. A point is that which has no parts. 2. A line is that, which has length without breadth, and its bounds or extremes are points. 3. A ſurface is that, which has length and breadth only, and the bounds thereof are lines. 4. A ſolid is that, which has length, breadth, and thickneſs, and the bounds are ſurfaces. 5. A right (or ſtrait) line is that which lies evenly between its extremes; or it is the neareſt diſtance between two points. 6. A plane ſurface is that, which is every where perfectly flat and even. 7. An angle is the inclination, or opening of two right lines meeting in a point, as D. Plate I. (*fig.* 1.) 8. When one right line DC, (*fig.* 2.) ſtanding upon another AB, makes the angles on both ſides equal, thoſe angles are called right angles; and that line CD is ſaid to be perpendicular to the other AB on which it inſiſts. 9. An acute-angle is that, which is leſs than a right angle, as D, (*fig.* 1.) 10. An obtuſe angle is that, which is greater than a right angle, as F, (*fig.* 3.) 11. The proper diſtance of two points, is the neareſt diſtance or right line reaching from the one to the other. 12. The proper diſtance of a point from a line, is its neareſt diſtance, and is a right line drawn from that point, perpendicular to, and terminating in, the line given. 13. Parallel (or equidiſtant) right lines, are ſuch, which being in the ſame plane ſurface, if infinitely produced, would never meet. 14. A figure is a bounded ſpace, and is either a ſurface, or a ſolid. 15. A right lined plane figure is that, formed in a plane ſurface, whoſe terms, or bounds, are right-lines. 16. All plane figures, bounded by three right lines, are called triangles. 17. An equilateral triangle is that, whoſe bounds or ſides are all equal. 18. An iſoſceles triangle is, that which has two of its ſides equal, the other ſide being either greater or leſs than thoſe equal ſides. 19. A ſcalene triangle is one which has all the three ſides unequal. 20. A right angled triangle is that which has one right angle, as ACB; (*fig.* 4.) whereof the ſide AB oppoſite to the right angle, is called the hypothenuſe. 21. An obtuſe angled triangle is that which has one obtuſe angle. 22. An acute angled triangle is that which has all its angles acute. 23. Every plane figure bounded by four right lines, is called a quadrangle, or quadrilateral. 24. Any quadrangle, whoſe oppoſite ſides are parallel, is called a parallelogram, as ABCD, (*fig.* 35.) 25. A parallelogram, whoſe angles are all right ones, is called a rectangle, as ABCD, (*fig.* 36.) 26. A ſquare is a parallelogram whoſe ſides are all equal, and its angles all right ones, as ABCD, or EFGH, (*fig.* 37 and 38.) 27. A rhombus is a parallelogram whoſe ſides are all equal, but its angles not right. 28. All other plane four-ſided figures, beſides theſe, are called trapeziums. 29. A right line joining any two oppoſite angles of a four-ſided figure, is called a diagonal. 30. That ſide AB, (*fig.* 5.) upon which any parallelogram ACEB, or triangle ACB is ſuppoſed to ſtand, is called the baſe; and the perpendicular CD falling thereon from the oppoſite angle C, is called the altitude of the parallelogram, or triangle. 31. All plane figures contained under more than four ſides, are called polygons; whereof thoſe having five ſides, are called Pentagons; thoſe having ſix ſides, hexagons; and ſo on. 32. A regular polygon is one whoſe angles, as well as ſides, are all equal. 33. A circle is a plane figure, bounded by one curve line APCD, (*fig.* 6.) called its circumference, every where equally diſtant from a point E within the circle, called the center thereof. 34. The radius of a circle, is the diſtance of the center from the circumference, or a right line EA drawn from the center to the circumference.

AXIOMS, or SELF-EVIDENT TRUTHS.

1. Things, equal to one and the ſame thing, are alſo equal to each other. 2. Every whole is greater than its part. 3. Every whole is equal to all its parts taken together. 4. If to equal things, equal things be added, the wholes will be equal. 5. If from equal things, equal things be taken away, the remainders will be equal. 6. If to, or from unequal things, equal things be added, or taken away, the ſums, or remainders, will have the ſame difference, as the unequal things firſt propoſed. 7. More than one right-line cannot be drawn from one given point A to another point B. A————B.

LEMMA I. If two points, D, F, (*fig.* 7.) in a right-line MN, are poſited at unequal diſtances DC, FE, from another right-line AB in the ſame plane ſurface; thoſe two lines, being infinitely produced, on the ſide of the leaſt diſtance EF, will meet each other. For if they will not meet, then muſt the lines be parallel; and conſequently every where equidiſtant, (by Definition 13) which is contrary to the hypotheſis.

LEMMA II. If two right lines (*fig.* 8 and 9.) CA, CB, making an angle C, be reſpectively equal to two other right lines FD, FE, making an angle F, and the angles which they make C, and F, be likewiſe equal; the right-lines AB, DE joining their extremes will be equal, and the two triangles ACB, DFE, equal in all reſpects. For, conceive the triangle DFE to be removed, and ſo applied to the triangle ABC, that the point F may coincide with C, and the ſide FD fall upon the ſide CA; then, becauſe FD is ſuppoſed equal to CA, the point D will alſo fall upon A. And, the angle F being equal to the angle C, the ſide FE will fall upon CB; and conſequently the point E upon the point B, becauſe FE is ſuppoſed equal to CB. Therefore, all the bounds of the two triangles coincide, and the baſes, AB, and DE, and the angles oppoſite to the equal ſides, are alſo equal.

The Signification of SIGNS.

Two letters with the power of 2 or 3 over the latter, denotes the ſquare or cube of a line denoted by ſuch letters; thus, AB^2; AB^3, &c. denote the ſquare and cube of the line AB reſpectively; when three letters come together they denote an angle, of which the middle letter is the angular point. The ſign ⊏, denotes that the quantity preceding it, is greater than that which comes after it. The ſign ⊐, denotes that the quantity preceding it, is leſs than that which comes after it. For the other marks and characters, ſee Syſtem of ALGEBRA.

THEOREM I. A line (AB) (*fig.* 10) ſtanding upon another line (CD) makes with it two angles (ABC), (ABD) which, taken together, are equal to two right angles. If the angles ABC, ABD, are equal, it is plain they make two right-angles (by Def. 8.) if unequal, let BE be perpendicular to CD, dividing the greater of them (ABC) into the parts EBC, EBA; then the former part EBC being a right-angle, and there maining part EBA, together with the whole leſſer angle ABD, equal to another right-angle EBD, (by Ax. 3.) the whole of both the propoſed angles, taken together, muſt neceſſarily be equal to two right-angles.

COROL. Hence (by Ax. 3.) all the angles at the ſame point on the ſame ſide of a right line are equal to two right-angles.

THEOREM II. If one line (AB) (*fig.* 11.) meeting two others (BC, BD) in the ſame point (B), makes two angles with them (ABC, ABD) which together are equal to two right angles; theſe lines (BC, BD) will form one continued right-line. For, if poſſible, let BH, and not BD, be the continuation of the right-line CB; then the angles ABC and ABH being = two right angles = ABC and ABD; if from theſe equal quantities, ABC, which is common to both, be taken away, there will remain ABH = ABD.

THEOREM III. The oppoſite angles (DEB, AEC), (*fig.* 12.) made by two lines (DC, BA) interſecting each other, are equal. For DEB + DEA = two right angles, (by Theorem I.) = AEC + DEA; whence, by taking away DEA, common, there remains DEB = AEC.

THEOREM IV. Two right lines (AB,CD) (*fig.* 13.) perpendicular to one and the ſame right line (EF), are parallel to each other. If you ſay, they are not parallel; then let them, when produced out, meet in ſome point, as G. In EA, produced (if neceſſary) let there be taken EH = EG; and let the right line FH be drawn. The triangles EHF and EGF, having EH = EG, the angle HEF = GEF, (by Def. 8.) and EF common, are therefore equal in all reſpects (by Ax. 10.) and ſo, the angle EFH being = EFG (EFD) = a right angle, HFDG (as well as HEG) muſt be one continued right-line: (by Theorem II.) which, by Axiom 8, is impoſſible. Therefore AB and CD are parallels.

THEOREM V. Perpendicular (EF, GH) (*fig.* 14.) to one (AB) of two parallel lines (AB, CD) terminated by thoſe lines, are equal to each other; and alſo perpendicular to the other of the two parallels (CD). For, AB and CD being parallel to each other, GH can neither be greater, nor leſs than EF; and therefore muſt be equal to it. If you ſay, that EF is not perpendicular to CD; then let FM be perpendicular to EF, meeting GH produced (if neceſſary) in M; ſo ſhall FM be parallel to AB by Theorem IV; and conſequently GM = EF by Theorem V. = GH; which by Axiom 2. is impoſſible. Therefore EF is perpendicular to CD. And by the ſame argument, GH is perpendicular to CD.

COROLLARY. Hence, through the ſame point F, more than one parallel cannot be drawn to the ſame line AB.

THEOREM VI. A line (AB) (*fig.* 15.) interſecting two parallel lines (SR, QP) makes the alternate angles SDC, PCD, equal to each other.

Let CF and DE be perpendicular to QP, and SR; then theſe lines FC and DE are likewiſe parallels by Theorem IV; and ſo the triangles CFD and CDE, having the ſide CF = DE, FD = CE, and the angle F = E they will alſo have the angle FDC = ECD by Lemma 2.

COROLLARY I. Hence, a line interſecting two parallel lines, makes the angles on the ſame ſide, equal to each other.

COROLLARY II. Hence, alſo, a line falling upon two parallel lines, makes the ſum of the two internal angles on the ſame ſide of it, equal to two right-angles.

THEOREM VII. If a line (AB) (*fig.* 16.) interſecting two other lines (PQ, RS), makes the alternate angles (DCP, CDS) equal to each other; then are thoſe two lines parallel. For, if poſſible, let ſome other line DT, and not DS, be parallel to PQ; then muſt CDT = DCP = CDS, which is impoſſible.

COROLLARY. Hence, if a line falling on two others, makes the angles above them, on the ſame ſide, equal to each other; then thoſe two lines are parallels.

THEOREM VIII. If one ſide (AB) (*fig.* 17.) of a triangle (ABC) be produced, the external angle (CBD) will be equal to both the internal oppoſite angles (A, C) taken together. For, let BE be parallel to AC; then will the angle C = CBE and the angle A = DBE; therefore C + A = CBE + DBE = CBD.

COROLLARY. Hence the external angle of a triangle is greater than either of the internal oppoſite angles.

THEOREM IX. The three angles of any plane triangle (ABC) (*fig.* 18.) taken together, are equal to two right angles. For, if AB be produced to D, then C + A = CBD by the laſt theorem, to which equal quantities let the angle CBA be added, then will C + A + CBA = CBD + CBA = two right angles, by Theorem I.

COROLLARIES. 1. If two angles in one triangle, be equal to two angles in another triangle, the remaining angles will alſo be equal. 2. If one angle in one triangle, be equal to one angle in another, the ſums of the remaining angles will be equal. 3. If one angle of a triangle be right, the other two taken together, will be equal to a right angle. 4. The two leaſt angles, of every triangle, are acute.

THEOREM X. The four inward angles of a quadrangle (AB CD) (*fig.* 10.) taken together, are equal to four right-angles Draw the diagonal AC, then the three angles of the triangle ABC being = two right-angles (by laſt theorem) and thoſe of the triangle ACD equal alſo to two right angles; it follows that the ſum of all the angles of both triangles, which make the four angles of the quadrangle, muſt be equal to four right-angles.

COROLLARY I. Hence, if three of the angles be right ones, the fourth will alſo be a right-angle.

COROLLARY II. Moreover, if two of the four angles, be equal to two right-angles, the remaining two together will likewiſe be equal to two right-angles.

SCHOLIUM. If from any point P, (*fig.* 20) within a polygon ABCDE, lines be drawn to all the angles, the ſum of all the angles of the triangles, thus formed, will be equal to twice as many right-angles as the polygon has ſides. Therefore, ſeeing all the angles about the point P, are equal to four right-angles, it is manifeſt, that all the angles of the polygon, taken together, will be equal to twice as many right-angles, wanting four, as the polygon has ſides.

THEOREM XI. The angles (A, B,) (*fig.* 21) at the baſe of an iſoſceles triangle (ABC) are equal to each other. For, let the line CD biſect, or divide the angle ACB into two equal parts ACD, BCD, and meet AB in D; then the triangles ACD, BCD, having AC = BC, CD common, and the angle ACD = BCD, will alſo have the angle A = B, by Lemma 2.

COROLLARY I. Hence, the line which biſects the vertical angle of an iſoſceles triangle, biſects the baſe, and is perpendicular to it.

COROLLARY II. Hence it appears alſo, that every equilateral triangle is likewiſe equiangular.

THEOREM XII. In any triangle (ABC) (*fig* 22) the greateſt ſide ſubtends the greateſt angle. Let AB be greater than AC; in which let there be taken AD = AC; drawing CD. The triangle ADC being iſoſceles, the angles ACD are ADC and therefore equal; whence ACB, which exceeds the former of them, muſt alſo exceed the latter ADC, and conſequently, much more exceed B, which is leſs than ADC.

Theorem XIII. If the three ſides (AB, AC, CB) (*fig.* 23) of one triangle, be equal to the three ſides (DE, DF, FE) of another triangle, (*fig.* 24) each to each reſpectively; then the angles oppoſed to the equal ſides will alſo be equal. Let the angle BA G = DAG = DF, and let GB and GC be drawn; ſo ſhall the triangles ABG and DEF be equal in all reſpects, by Lemma 2; therefore, AG being = DF = AC, and BG = EF = BC, the angle ACG is alſo = AGC, and BCG = BGC by theorem 11; and conſequently ACB = AGB = DFE: therefore the triangles ABC, DEF are equal in all reſpects.

Theorem XIV. If two triangles (ABC, DEF) (*fig.* 25, and 26,) mutually equiangular, have two correſponding ſides (AB, DE) equal to each other, the other correſponding ſides will alſo be equal. If you ſay BC is greater than EF; from BC let a part BG be taken = EF, and let AG be drawn. The triangles ABG, DEF, having AB = DE, BG = EF, and B = E (by hypotheſis), will alſo have BAG = D; but D = BAC; therefore BAG = BAC; which is impoſſible.

Corollary. Hence, equiangular triangles, having any two correſponding ſides equal, are equal to each other.

Theorem XV. If two right angled triangles (ABC, DEF) (*fig.* 27 and 28) having equal hypothenuſes (AC, DF), have two other ſides (BC, EF) likewiſe equal; the remaining ſides (AB, DE) will be equal, and the two triangles equal in all reſpects. In AB produced, take BG = ED, and let GC be drawn: then, the triangles BCG and DEF, having BG = ED, BC = EF, and the angle CBG = E, will alſo have the angle G = D, and CG = DF = AC: whence, the triangle ACG being iſoſceles, the angle G, or D, will be = A; and conſequently F alſo = ACB; therefore the triangles ABC and DEF, being mutually equiangular, and having AC = DF, they are equal in all reſpects.

Theorem XVI. If two angles (A, B) of a triangle (ABC) (*fig.* 29) be equal, the ſides (BC, AC) ſubtending them will likewiſe be equal. Let CD biſect the angle ACB, and meet AB in D; then the triangles ACD, BCD being equiangular, and having CD common to both, they will alſo have AC = BC.

Theorem XVII. Of all the right lines (PA, PB, PC) (*fig.* 30) falling from a given point (P) upon an infinite right-line (RS), that (PA) is the leaſt which is perpendicular to it; and, of the reſt, that (PB) which is the neareſt the perpendicular is leſs than any other (PC) at a greater diſtance. For BAP being a right-angle, ABP will be acute (by Cor. 4 to Theorem 9) and therefore $AP \sqsupset BP$ by Cor. to Theo. 12. Again, when PB and PC are both on the ſame ſide of the perpendicular PA; then is $BCP \sqsubset$ right angle $\sqsubset BCP$, and conſequently $PC \sqsubset PB$. If PB be on the contrary ſide of the perpendicular to PC, from AC, let AB be taken = AB; then the two lines PB, PB, will be alſo equal; and therefore PC, which exceeds the one (by the preceding caſe) will alſo exceed the other.

Theorem XVIII. The oppoſite ſides (AB, DC) of any parallelogram (ABCD) (*fig.* 31) are equal, as are alſo the oppoſite angles (B, D); and the diagonal (AC) divides the parallelogram into two equal parts. For, AB, DC, and AD, BC, being parallels, the angle BAC is = DCA, and BCA = DAC, therefore the equiangular triangles ABC, ADC having AC common, are equal in all reſpects, by Theorem 14.

Cor. Hence, if one angle (B) of a parallelogram be a right-angle, all the other three will be right ones: for D, being = B, is a right angle; and BCD is = B, and DAB = D, by Theor. V.

Theorem XIX. Every quadrilateral (ABCD) whoſe oppoſite ſides are equal, is a parallelogram.

Let the diagonal AC (*fig.* 31) be drawn; then the triangles ABC, ADC, being mutually equilateral, they will alſo be mutually equiangular (by Theo. 13); conſequently AB will be parallel to DC, and AD to BC, (by Theo. 7)

Theorem XX. The lines (AD, BC) (*fig.* 32) joining the correſponding extremes of two equal and parallel lines (AB, DC) are themſelves equal and parallel. Let the diagonal BD be drawn. Becauſe AB and DC are parallel, the angle ABD is = CDB; therefore, BA being = DC and BD common, the remaining ſides and angles will likewiſe be reſpectively equal; and conſequently AD parallel to BC.

Theorem XXI. If, in one ſide (AB) of a triangle (ABC), (*fig.* 33) from three points (D, F, H) at equal diſtances (DF, FH), lines (DEM, FG, HI) be drawn parallel to the baſe, the parts (EG, GI) of the other ſide (AC) intercepted by them, will alſo be equal to each other. Let NGM be parallel to AB, interſecting HI and DE in N and M. Then, the triangles IGN, MGE, having the angle IGN = EGM, ING = M, (by Theo. 7) and (by Theo. 18) GN (= FH = FD) = GM, will alſo have GI = GE (by Theo. 14).

Cor. I. Hence, if one ſide of a triangle be divided into any number of equal parts, and from the points of diviſion lines be drawn parallel to the baſe, cutting the other ſide, they will alſo divide it into the ſame number of equal parts.

Cor. II. Alſo if two lines FG, HI, cutting the ſides of a triangle, be parallel to each other, and another line DE be ſo drawn as to cut off FD = FH and GE = GI, this line DE will be parallel to the two former.

Theorem XXII. If in the ſides of a ſquare (ABCD), (*fig.* 34) equally diſtant from the four angular points, there be taken four other points, (EF, G, H,) the figure (EFGH) thus formed, ſhall alſo be a ſquare. For the wholes AD, DC, CB, BA, being equal, and alſo the parts AE, DF, CG, BH, the remaining parts ED, FC, GB, HA, muſt conſequently be equal; (by Ax. 5) whence all the angles D, C, B, A, being equal (by Ax. 7) the ſides EF, FG, GH, HE, will be equal likewiſe (by Lemma 2) and the angle DEF, = AHE. Therefore becauſe DEH is = A + AHE, (by Theo. 8) if from theſe, the equal angles DFF, AHE, be taken away, there will remain HEF = A = a right-angle. By the ſame argument (or by Theor. 19th, and the Carol. to the 18th) the other three angles will be right-angles.

SECT. II. *Of Parellograms, Rectangles, &c.*

Definitions. 1. In a parallelogram ABCD, (*fig.* 35) if two right-lines GI, FH, parallel to the ſides, interſecting the diagonal in the ſame point E, be drawn, dividing the parallelogram into four other parallelograms; thoſe two EA, and EC, through which the diagonal does not paſs, are called complements; and the other two FG, and HI, parallelograms about the diagonal. 2. Every rectangle is ſaid to be contained under the two right-lines AB, BC, (*fig.* 36) that are the baſe and altitude thereof.

Theorem I. The rectangles (BD, FH) *fig.* 37 and 38) contained under equal lines, are equal. For, let the diagonals AC, EG, be drawn: then becauſe AB = EF, BC = FG, and B = F, the triangles ABC, EFG, are equal. And in the very ſame manner will ADC and EHG appear to be equal; therefore the whole rectangle ABCD is alſo equal to the whole rectangle EFGH.

Theorem II. Parallelograms (ABCD, BCFE) (*fig.* 39 and 40) ſtanding upon the ſame baſe (BC) and between the ſame parallel (BC, AF) are equal. For, ſince (in *fig.* 39.) the angle F = BEA, and CDF = A, the triangles FDC, EAB, are equiangular; they are alſo equal, becauſe CF = BE: therefore, if each be taken from the whole figure ABCF, there will remain ABCD = EBCF.

Corol. I. Hence, triangles BAC, BFC, (*fig.* 40) ſtanding upon the ſame baſe, and between the ſame parallels, are equal.

Corol. II. Hence all parallelograms, or triangles, whatever, whoſe baſes and altitudes are equal, are equal among themſelves.

Theorem III. The complements (EC, EA) (*fig.* 35.) of any parallelogram (AC) are equal. For, the whole triangle DCB being equal to the whole triangle DAB, and the parts DIE, EFB, reſpectively equal to the parts DHE, EGB, the remaining parts EC, EA, muſt likewiſe be equal.

Theorem IV. If a right-line (AB) (*fig.* 41.) be any wiſe divided into two parts (AC, BC), the ſquare of the whole line will be equal to the ſquares of both the parts, together with two rectangles under the ſame parts. Let ABGI be the ſquare of AB, and CBEF that of BC, and let EF and CF be produced to meet the ſides of the ſquare ABGI in M and N. From the equal quantities CM, EN, take the equal quantities CF and EF; and there remains FM = FN; therefore, all the angles of the figure being right ones, NM is a ſquare upon FN (= AC); and AF, FG are equal to two rectangles under BC and AC, by theorem 1, of this ſection: but AG = BF + FI + AF + FG, or $AB^2 = BC^2 + AC^2 + 2AC \times BC$.

Corol. I. Hence, the ſquare of any line is equal to four times the ſquare of half that line.

Corol. II. Hence, alſo, if two ſquares be equal, their ſides muſt be equal.

Theorem V. The difference of the ſquares (ABEH, ACIK) (*fig.* 42.) of any two unequal lines (AB, AC), is equal to a rectangle under the ſum and difference of the ſame lines. In EB, produced, take BF = AC; let FG be drawn parallel to EH, and let CI be produced both ways, to meet EH and FG in D and G. It is evident that DF is a rectangle, whoſe baſe GF (= CB) = the difference of the given lines AB, AC; and whoſe altitude FE (becauſe BE = BA, and BF = AC) is = the ſum of the ſame lines: but this rectangle DF is = DB + GB = DB + DK (becauſe DK = GB) = the ſquare AE—the ſquare AI.

Theorem VI. The ſquare made upon the ſide (AC) ſubtending the right-angle of a plane triangle (ABC), is equal to both the ſquares (BE, BG) made upon the ſides (AB, BC) containing that angle. Let the ſides of the ſquares BE, BG be produced to meet each other in L and D; in which take KL and IG each equal to AE (or AB); and let CI, IK, and KA be drawn. Since ABH and FBC (which are continued right lines) are equal to each other; EL, DG, ED, and LG, will be all equal among themſelves; and ſo the angles E, D, G and L, being all right ones, EDGL will be a ſquare, and conſequently ACIK a ſquare likewiſe (by Theorem 21, Sect. I. Now, if from the ſquare DL, the four equal triangles ADC, CGI, ILK, and KEA, be taken away, there will remain the ſquare AI; and, if from the ſame DL, the two equal parallelograms DB, BL (which are equal to the ſaid four triangles, becauſe DB = two of them) be taken away; then there will remain the two ſquares BE and BG. Conſequently the ſquare AI is = the two ſquares BE and BG.

Cor. Hence, the ſquare upon either of the ſides, including the right angle, is equal to the difference of the ſquares of the hypothenuſes and the other ſide.

Theorem XII. The difference of the ſquares of the two ſides (AC, BC) of any triangle (ABC) (*fig.* 43 and 44.) is equal to the difference of the ſquares of the two lines, or diſtances (AD, BD) included between the extremes of the baſe (AB) and the perpendicular (CD) of the triangle. For, ſince $AC^2 = DC^2 + AD^2$, and $BC^2 = DC^2 + BD^2$ (by the precedent), it is evident that the difference of AC^2 and BC^2 will be equal to the difference between $DC^2 + AD^2$ and $DC^2 + BD^2$, or between AD^2 and BD^2, by taking away DC^2, common, from both.

Cor. I. The difference of the ſquares, or the rectangle under the ſum and difference of the two ſides of any triangle, is equal to the rectangle under the ſum and difference of the diſtances included between the perpendicular and the two extremes of the baſe.

ELEMENTS OF GEOMETRY.

SECT. III. *Of the Circle.*

Definitions. 1. Any right-line DP, paſſing through E (*fig.* 6.) the center of a circle, and terminating in the circumference at both ends, is called a diameter. 2. An arc of a circle, is any portion of the periphery, or circumference, as BAF. 3. The chord, or ſubtenſe of an arc BAF, is a right-line BF, joining the two extremes of that arc. 4. A ſemi-circle is a figure contained under any diameter and either part of the circumference cut off by that diameter, as DAPE. 5. A ſegment of a circle is a figure contained under an arc BAF, and its chord BF. 6. A ſector of a circle is a figure contained under two right-lines ED, EC, drawn from the center to the circumference, and the arc DC included betwixt them. When the two lines ſtand perpendicular to each other, then the ſector is called a quadrant. 7. An angle ABC (*fig.* 45,) is ſaid to be a ſegment of a circle ABC, when, being in the periphery thereof, the right-lines BA, BC, by which it is formed, paſs through the extremes of the chord AC bounding that ſegment. 8. An angle ABC (*fig.* 45) in the periphery, comprehended by two right-lines BA, BC, including an arc of the circle, ADC, is ſaid to ſtand upon that arc. 9. A right-line is ſaid to be applied, or inſcribed in a circle, when both its extremes are in the periphery thereof. 10. A right-lined figure is ſaid to be inſcribed in a circle, when all its angles are in the circumference of the circle. 11. A circle is ſaid to be deſcribed about a right-lined figure, when the periphery of the circle paſſes through all the angles of that figure. 12. A right-lined figure is ſaid to be deſcribed about a circle, when all the ſides thereof touch the circle. 13. A circle is ſaid to be inſcribed in a right-lined figure, when it is touched by all the ſides of the right-lined figure. 14. A right-lined figure is ſaid to be inſcribed in a right-lined figure, when all the angles of the former are ſituate in the ſides of the latter.

Theorem I. If the ſides (AB, BC, CD, &c.) (*fig.* 46,) of a polygon inſcribed in a circle, be equal, the angles (AOB, BOC, COD, &c.) at the center of the circle, ſubtended by them, will likewiſe be equal. For AO, BO, CO, &c. being equal to each other, as well as AB, BC, CD, &c. the triangles AOB, BOC, COD, are mutually equilateral; and therefore have all the angles AOB, BOC, &c. equal to each other by Theo. 13, Section I.

Theorem II. Any chord (AB) of a circle, (*fig.* 47,) falls wholly within the ſame; and a perpendicular (CD) let fall thereon, from the center of the circle, will divide it into two equal parts. Let C, A, and C, B, be joined; and through any point E in the chord AB, let the right-line CEF be drawn, meeting the circumference in F. It is evident, becauſe $CA = CB$, that theſe equal lines are on different ſides of the perpendicular CD; by Theory 17. Sect. 1; and ſo, CE being $\sqsupset$ CA or CF, the point E (take it where you will in the line AB) and conſequently the line AB itſelf, will fall within the circle. Moreover, becauſe the triangles ACD, BCD, have $CA = CB$, and CD common, thence will AD be alſo $= BD$.

Cor. Hence a line biſecting any chord at right-angles, paſſes through the center of the circle.

Theorem III. Any two chords (AB, DE) (*fig.* 48.) equally diſtant from the center (O) of a circle, are equal to each other. Let the perpendiculars OF, OC, be drawn, and let O, D, and O, A, be joined. Becauſe $OF = OC$, $OD = OA$, and F and C are both right angles, therefore is $DF = AC$ by Theorem 15, Sect. I. and conſequently $DE = 2DF = 2AC = AB$.

Theorem IV. A right line (FD) (*fig.* 49,) drawn through any point (A) in the circumference of a circle, at right angles to the radius (EA) terminating in that point, will touch the circle. From any point in FD, to the center E, let the right line BE be drawn; which being greater than AE, the point B muſt, neceſſarily, fall out of the circle: and therefore, as the ſame argument holds good with regard to every other point in the line FD (except A), it is manifeſt that this line cuts off no part of the circle, but touches it in one point only.

Theorem V. The angle (BDC) at the center of a circle, is double to the angle (BAC) at the circumference, when both angles ſtand upon the ſame arch (BC). See *fig.* 50, 51, and 52. Let the diameter ADE be drawn. In the firſt caſe (where AB paſſes through the center) $BDC = A + C = 2A$. In the ſecond caſe, $BDE = 2BAE$, (by caſe 1.); to which adding $CDE = 2CAE$, we have $BDC = 2BAC$. In the third caſe, $CDE = 2CAE$ (by caſe 1.) from whence, ſubtracting $BDE = 2BAE$ there remains $BDC = 2BAC$.

Theorem VI. All angles (EAF, EBF) *fig.* 53, 54. in the ſame ſegment (EABF) of a circle, are equal to each other.

Case I. If the ſegment be greater than a ſemi circle, from the center C draw CE and CF; then EAF and EBF, being each of them = to half ECF, they muſt neceſſarily be equal to each other.

Case II. If the ſegment be leſs than a ſemi-circle, let H be the interſection of EB and AF, then the triangles AEH and BFH, having the angle $AHE = BHF$, and $AEH = BFH$ (by caſe 1.) they will alſo have $EAH = FBH$ by Cor. to Theory 9, Sect. I.

Cor. Angles in the circumference ſtanding upon equal chords of the ſame circle are equal; and from the ſameneſs of equal circles it may be added as a further corollary, that all angles in the circumferences, ſtanding upon equal ſubtenſes of circles, having equal diameters, are equal to each other. And the ſubtenſes of equal angles, in the circumference of circles, having equal diameters, are alſo equal.

Theorem VII. The angle ACB (*fig.* 55,) in a ſemi-circle, is a right angle. Let the diameter CDE be drawn. Becauſe $ACD =$ half ADE, and $BCD =$ half BDE, by Theorem V. of this Section; therefore is $ACD + BCD$ $(= ACB) =$ half of ADE and BDE $=$ half two right angles $=$ one right angle.

Theorem VIII. The angle CAB (*fig.* 56.) included by a tangent to a circle and a chord (AC) drawn from the point of contact (A), is equal to the angle (AEC) in the alternate ſegment. Let the diameter AOF be drawn, and E, F, be joined. The line DB, falling wholly above the circle, OA is the leaſt line that can be drawn to it from the center O, by Theorem 17, Sect. I. and Theorem 4 of this Section; for OAB is a right-angle; and FEA is alſo a right angle by the preceding theorem; therefore, if from theſe equal angles, the equal angles, FAC, FEC, (ſtanding on the ſame arc FC) be taken away, there will remain $BAC = AEC$.

Theorem IX. The vertical angle (ABC) of any oblique-angled triangle (ACB) inſcribed in a circle (ABCD) is greater or leſs than a right-angle, by the angle (CAD) comprehended under the baſe (AC) and the diameter (AD) drawn from the extremity of the baſe. For, BD being drawn, ABD will be a right angle, and $CAD = CBD$; therefore, in the firſt caſe, $ABC =$ right angle $+ CAD$; and in the ſecond, $ABC =$ right-angle $- CAD$.

Theorem X. If any ſide (BC) (*fig.* 59.) of a quadrilateral (ABCD) inſcribed in a circle, be produced out of the circle, the external angle (ECD) will be equal to the oppoſite internal angle (BAD). Let the diameter BF be drawn, and let AF and CF be joined; then the angle BAF being a right angle $(= BCF) = ECF$, and DAF alſo $= DCF$, ſtanding both on the ſame arc DF; thence will the remainders BAD and ECD be alſo equal.

Cor. Hence the oppoſite angles BAD, BCD of any quadrilateral inſcribed in a circle, are together equal to two right angles.

Theorem XI. If two lines AB, CD (*fig.* 60 and 61) terminated by the periphery on both ſides, cut each other within a circle, the rectangle $(AP \times BP)$ contained under the parts of the one, will be equal to the rectangle $(CP \times DP)$ contained under the parts of the other.

Case I. If one of the two lines (AB) paſſes through the center O; then let OQ be drawn perpendicular to the other CD, and let OC be joined; then becauſe $QD = QC$, DP is equal to the difference of the ſegments CQ and PQ: but the rectangle under the ſum and difference of the two ſides OC, OP, of any triangle COP, is equal to the rectangle under the whole baſe CP, and the difference of its two ſegments by Cor. to Theory VII. Sect. II. therefore, the ſum of the two ſides OC, OP being $(= OA + OP) = AP$, and their difference $(= OB - OP) = BP$, thence is the rectangle contained under AP and BP equal to the rectangle contained under CP and DP.

Case II. If neither of the two lines paſs through the center, let the diameter EPF be drawn; then, by the preceding caſe, $AP \times BP = FP \times EP = CP \times DP$.

Theorem XII. If from two points (A,) C (*fig.* 62.) in the circumference of a circle, two lines (AP, CP) be drawn, to paſs through and meet without the circle, the rectangle $(AP \times BP)$ contained under the whole and the external part of the one, will be equal to the rectangle $(CP, \times DP)$ contained under the whole, and the external part of the other. Through the center O, let PF be drawn, meeting the circumference in E and F; let OQ be perpendicular to AP, and let A, O, be joined. Then, the rectangle contained under PF $(= PO + OA)$ and PE $(= PO - OA)$ is $=$ the rectangle contained under AP and PB. After the very ſame manner, $PF \times PE = CP \times DP$: therefore $AP \times BP = CP \times DP$.

Cor. I. Hence, if PS be a tangent at S, and the radius OS be drawn; then, PF being $=$ the ſum of PO and OS, and PE $=$ their difference; it follows, that $PS^2 = PF \times PE = PC \times PD$.

Theorem XIII. If from the center (C) (*fig.* 63.) of a circle, to a point (A) in any chord (BD), a line (CA) be drawn; the ſquare of that line, together with the rectangle contained under the two parts of the chord, will be equal to a ſquare made upon the radius of the circle. Let EAF be another chord, perpendicular to CA, and let C, E, be joined. Since AF = AE, thence will AE × AE = AB × AD by Theorem 11, of this Sect. to which equal quantities, adding AC^2 we have $CE^2 = AB \times AD + AC^2$ by theorem 6, Sect. II.

Cor. Hence the ſquare of a line (AC) drawn from any point in the baſe of an iſoſceles triangle (BCD) to the oppoſite angle, together with the rectangle of the parts of the baſe, is equal to a ſquare made upon one of the equal ſides of the triangle.

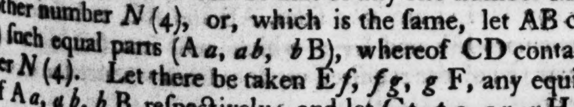
Theorem XIV. The rectangles contained under the correſponding ſides of the equiangular triangles (ABC, DEF) *fig*. 64, taken alternately, are equal. I ſay, if A = D, B = E and C = F, then will AB × DF = AC × DE. In BA produced, let AG be taken = DF; let GCB be the circumference of a circle paſſing through the three points B, C, G, meeting CA produced in H; and let G, H, be joined. Becauſe the angle H = B, by Theor. VI. Sect. III. = E, HAG = BAC = D, and AG = DE, thence is AH = DE; and therefore AC × DE = AC × AH = AB × AG = AB × DF.

SECT. IV. *Of the Ratios of Geometrical Quantities.*

Definitions. Ratio is the proportion which one magnitude bears to another magnitude of the ſame kind, with reſpect to quantity. 2. Three quantities, or magnitudes A, B, C, are ſaid to be proportional, when the ratio of the firſt A to the ſecond B, is the ſame as the ratio of the ſecond B, to the third C. 3. Four quantities A, B, C, D, are ſaid to be proportional, when the ratio of the firſt A to the ſecond B, is the ſame as the ratio of the third C to the fourth D. 4. Of three proportional quantities, the middle one is ſaid to be a mean-proportional between the other two; and the laſt, a third-proportional to the firſt and ſecond. 5. Of four proportional quantities, the laſt is ſaid to be a fourth-proportional to the other three, taken in order. 6. Quantities are ſaid to be continually proportional (or in continued proportion) when the firſt is to the ſecond, as a ſecond to the third, as the third to the fourth, as the fourth to the fifth, and ſo on. 7. In a ſeries, or rank of quantities continually proportional, the ratio of the firſt and third, is ſaid to be duplicate to that of the firſt and ſecond; and the ratio of the firſt and fourth, triplicate to that of the firſt and ſecond. 8. Any number of quantities, A, B, C, D, being given, or propounded, the ratio of the firſt (A) to the laſt (D) is ſaid to be compounded of the ratios of the firſt to the ſecond, of the ſecond to the third, and ſo on. 9. Ratio of equality, is that which equal quantities bear to each other. 10. Inverſe ratio is, when the antecedent is made the conſequent, and the conſequent the antecedent. Thus, if 2 : 1 :: 6 : 3; then, inverſly, 1 : 2 :: 3 : 6. 11. Alternate proportion is, when antecedent is compared with antecedent, and conſequent with conſequent. As, if 2 : 1 :: 6 : 3; then, by alternation (or permutation) it will be 2 : 6 :: 1 : 3. 12. Compounded ratio is, when the antecedent and conſequent, taken as one quantity, are compared either with the conſequent, or with the antecedent. Thus, if 2 : 1 :: 6 : 3; then, by compoſition, 2 + 1 : 1 :: 6 + 3 : 3, and 2 + 1 : 2 :: 6 + 3 : 6. 13, Divided ratio is, when the difference of the antecedent and conſequent is compared, either with the conſequent, or with the antecedent. Thus, if 3 : 1 :: 12 : 4; then by diviſion, 3 — 1 : 1 :: 12 — 4 : 4, and 3 — 1 : 3 :: 12 — 4 : 12. 14. Similar (or like) right lined figures are ſuch, which have all their angles equal, one to another reſpectively, and alſo the ſides about the equal angles proportional.

Axioms. 1. The ſame quantity being compared with ever ſo many equal quantities, ſucceſſively, will have the ſame ratio to them all. 2. Equal quantities, have to one and the ſame quantity, the ſame ratio. 3. Quantities having the ſame ratio to one and the ſame quantity, or to equal quantities, are equal among themſelves. 4. Quantities, to which one and the ſame quantity has the ſame ratio, are equal. 5. If two quantities be referred to a third, that which is the greateſt will have the greateſt ratio. 6. If two quantities be referred to a third, that is the greateſt which has the greateſt ratio. 7. Ratios, equal to one and the ſame ratio, are alſo equal, one to the other. 8. If two quantities be divided into, or compoſed of parts, that are equal among themſelves, or all of the ſame magnitude; then will the whole of the one, have the ſame ratio to the whole of the other, as the number of the parts in the one, has to the number of equal parts in the other. 9. If the double, treble, or quadruple, &c. of every part of any quantity be taken, the aggregate will be the double, treble, or quadruple, &c. of the whole quantity propounded.

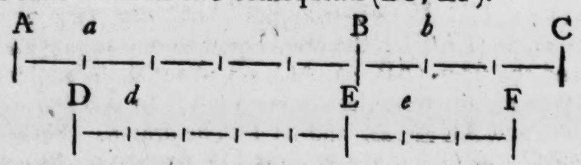
Theorem I. Equimultiples of any two quantities (AB, CD) are in the ſame ratio as the quantities themſelves.



Let the ratio of AB to CD be that of any one number *M* (3) to any other number *N* (4), or, which is the ſame, let AB contain *M* (3) ſuch equal parts (A*a*, *ab*, *b*B), whereof CD contains the number *N* (4). Let there be taken E*f*, *fg*, *g* F, any equimultiples of A*a*, *a b*, *b* B, reſpectively; and let G*p*, *p q*, *q r*, *r* H, be the ſame multiples of C*c*, *cd*, *de*, *e*D; ſo ſhall the whole EF be the ſame aſſigned multiple of the whole AB, and the whole GH of the whole CD, as each part in the one, is of its correſpondent in the other. And, ſince the parts A*a*, *ab*, *b*B, C*c*, *cd*, &c. are all equal, their equimultiples E*f*, *fg*, *g*F, G*p*, *pq*, &c. will alſo be equal. Therefore EF is in proportion to GH, as the number of the parts in EF is to the number of equal parts in GH, or (which is the ſame) as the number of parts in AB to the number of parts in CD, that is, as AB is to CD; which was to be demonſtrated.

Cor. Hence, like parts of quantities, have the ſame ratio as the wholes.

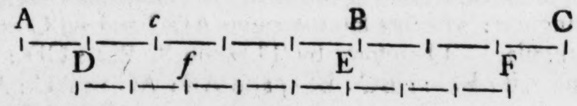
Theorem II. The two antecedents (AB, DE) of four proportional quantities, of the ſame kind (AB, BC, DE, EF) are in the ſame ratio with the two conſequents (BC, EF).



Let the common ratio of AB to BC, and of DE to EF, be that of any one number *M* (5) to any other number *N* (3); then will AB contain *M* (5) ſuch equal parts (A *a*) whereof BC contains *N* (3); and DE will, in like manner, contain *M* (5) ſuch equal parts (D*d*), whereof EF contains *N* (3); and ſo, AB and DE, as well as BC and EF, being equimultiples of A *a* and D *d*, thence will AB : DF :: A *a* (B *b*) : D *d* (E *e*) :: BC : EF.

Cor. The proportionality will ſubſiſt, when the conſequents are taken as antecedents, and the antecedents as conſequents.

Theorem III. Of four proportional quantities, (AB, BC, DE, EF) the ſum, or difference of the firſt antecedent and conſequent (AB ± BC) is to the firſt antecedent, or conſequent, as the ſum, or difference of the ſecond antecedent and conſequent (DE ± EF) is to the ſecond antecedent, or conſequent. Let what was premiſed in the demonſtration of the preceding theorem, be retained here: then will



AC (AB + BC) be in proportion to AB, as the number of parts in AC is to the number of equal parts in AB, or as the number of parts in DF (DE + EF) to the number of equal parts in DE, that is, as DF (DE + EF) is to DE. Again, if from AB and DE, be taken away B*c* = BC, and E*f* = EF, then will the difference A*c* be in proportion to AB, as the number of parts in A*c* (or D*f*) is to the number of parts in AB (or DE); that is, as D*f* is to DE. In the ſame manner it will appear, that AB + BC : BC :: DE + EF : EF; and AB — BC : BC :: DE — EF : EF.

Cor. Hence the ſum of the greateſt and leaſt of four proportional quantities, of the ſame kind, will exceed the ſum of the two means.

Theorem IV. Triangles (ACD, BCD) (*fig*. 65.) and alſo parallelograms (ADCQ, BDCP), having the ſame altitude, are to one another, in the ſame ratio, as their baſes (AD, BD). Let the baſe AD be to the baſe BD in the ratio of any one number *m* (3) to any other number *n* (2); or, which is the ſame, let AD contain *m* (3) ſuch equal parts whereof BD contains the number *n* (2). Then, the triangles AC*p*, *p*C*q*, BC*r*, *&c.* made by drawing lines from the points of diviſion to the vertex C, being all equal among themſelves; the triangle ACD will therefore be in proportion to the triangle BCD, as the number of equal parts in the former to the number of equal parts in the latter, or as the number of parts in AD to the number of parts in BD, that is, as AD to BD; whence, alſo, the parallelograms ADCQ, BDCP, being the doubles of their reſpective triangles, are likewiſe in the ſame ratio as their baſes AD and BD.

Theorem V. Triangles (ABC, DEF), (*fig*. 66 and 67) ſtanding upon equal baſes (AB, DE) are to one another, in the ſame ratio as their altitudes (CH, FI.) Let BP be perpendicular to AB, and equal to CH; in which let there be taken BQ = FI, and let AP and AQ be drawn. The triangle ABP is = ABC, and ABQ = DEF; but ABP (ABC) : ABQ (DEF) :: BP (HC) : BQ (FI), by laſt Theorem.

Theorem VI. If four lines are proportional (*fig*. 68 and 69,) (AB : CD :: DE : BF), the rectangle (AF) under the two extremes will be equal to the rectangle (CE) under the two means: and, if the rectangles under the extremes and means of four given lines (AB, CD, DE, BF) be equal, then are thoſe four lines proportional. In DE let DG be taken = BF, and let GH, parallel to DC, be drawn. 1. Hyp. AF : CG :: AB : CD by Theorem 4, in this Section, :: DE : BF :: DE : DG :: CE : CG; therefore, the conſequents of the firſt and laſt of theſe equal ratios being the ſame quantity CG, the two antecedents AF and CE muſt be equal. 2. Hyp. AB : CD :: AF : CG :: CE : CG :: DE : DG (BF.)

Cor. The two antecedents of four proportional lines are in the ſame ratio to each other, as the two conſequents.

Theorem VII. A line (BE) (*fig*. 70) drawn parallel to one ſide (CD) of a triangle (ACD) divides the other two ſides proportionally. (I ſay, AB : AC :: AE : AD, AB : BC :: AE : ED, and AC : BC :: AD : ED). Draw CE and DB; then will the triangles BEC and EBD be equal to each other; whence, by adding BEA to both, AEC will be alſo = ABD. But, AB : AC :: triangle AEB : triangle AEC (ABD) :: AE : AD; and

AB : BC : : triangle AEB : triangle CEB (DEB) : : AE : ED.

Cor. Hence a right-line, which divides two ſides of a triangle proportionally, is parallel to the remaining ſide.

Theorem VIII. In triangles (ABC, *abc*) (*fig* 71 and 72) mutually equiangular, the correſponding ſides (AB, *ab*, AC, *ac*) containing the equal angles (A, *a*) are proportional. In AB and AC (produced if neceſſary) take AD = *ab*, and AE = *ac*, and join D, E. Then, becauſe AB × AC = *ab* × AC, therefore is AB : *ab* : : AC : *ac*.

Cor. Hence equiangular triangles are ſimilar to each other.

Theorem IX. If two triangles (ABC, *abc*) (*fig*. 71 and 72) have one angle (BAC) in the one, equal to one angle (*bac*) in the other, and the ſides (AB, *ab*, AC, *ac*) about thoſe angles proportional; then are the triangles equiangular. In AB and AC, take AD = *ab*, and AE = *ac*, and let DE be drawn. Since AB : *ab* (AD) : : AC : *ac* (AE), therefore is DE parallel to BC, by Cor. to Theo. 7; whence the angle B = ADE = *b*, and the angle C = AED = *c*.

Theorem X. A right line (CD) (*fig*. 73.) biſecting any angle (ACB) of a triangle (ABC) divides the oppoſite ſide (AB) into two ſegments (AD, BD) having the ſame ratio with the ſides (AC, CB) containing that angle. Let AE and BF be perpendicular to CDE. Then the triangles ACE, CBF, and ADE, BDF, being, reſpectively, equiangular, it will be AD : BD : : AE : BF : : AC : BC, by Theorems 8 and 2, of this Section.

Theorem XI. A perpendicular (CD) (*fig*. 74.) let fall from the right angle (C) upon the hypothenuſe (AB) of a right-angled triangle (ABC) will be a mean proportional between the two ſegments (AD, BD) of the hypothenuſe; and each of the ſides containing the right angle, will be a mean proportional between its adjacent ſegment, and the whole hypothenuſe. For ſince the angle BDC is = BCA, and B common, the triangles BDC, BCA, are equiangular: after the ſame manner ADC and ABC appear to be equiangular. Therefore, by Theorem 8, BD : CD : : CD : AD; and AB : BC : : BC : BD; alſo AB : AC : : AC : AD.

Cor. Becauſe the angle in a ſemi-circle is a right-angle, it follows, that $CD^2 = BD \times AD$, $BC^2 = AB \times BD$, and $AC^2 = AB \times AD$. See Theo. 6, of this Section.

Theorem XII. If, in ſimilar triangles (ABC, EFG) (*fig*. 75 and 76) from any two equal angles (ACB, EGF) to the oppoſite ſides, two right-lines (CD, GH) be drawn, making equal angles with the homologous ſides (CB, GF); thoſe right-lines will have the ſame ratio as the ſides (AB, EF) on which they fall, and will alſo divide thoſe ſides proportionally. For, the triangles ADC, EHG, and BDC, FHG, (as well as the wholes ABC, EFG) being equiangular; thence is by Theorem 8 and Axiom 7, AB : EF (: : AC : EG) : : CD : GH; and AD : EH (: : DC : HG) : : BD : FH.

Theorem XIII. Equiangular triangles (ABC, EFG) (*fig*. 77 and 78) are in proportion to one another, as the ſquares (AK, EM) of their homologous ſides. Upon AB and EF let fall the perpendiculars CD and GH, and let the diagonals BI, FL, be drawn. Becauſe by Theorem 5 of this Sect. ABC : ABI : : CD : AI (AB); and by Theorem 12 : : GH : EF (EL) : : EFG : EFL; therefore, alternately, ABC : EFG : : ABI : EFL : : AK : EM. Cor. ſimilar right-lined figures as to one another as the ſquares of their homologous ſides.

SECT. V. *Geometrical Problems.*

Prob. I. At a given point (A) in an infinite right-line, (PQ) to erect a perpendicular; (*fig*. 79.) From any point D above the line PQ, as a center, through the given point A, let the circumference of a circle be deſcribed, interſecting PQ in E; draw the diameter EDB, and alſo BA; then the angle EAB, being in the ſemicircle EAB, is a right-angle.

Prob. II. From a given point (A) upon an infinite right line (PQ) to let fall a perpendicular (AB) (*fig*. 80.) From any point C in the line PQ, as a center, let the circumference of a circle be deſcribed through the given point A, interſecting PQ in D; and from the center D, with a radius equal to the diſtance of the points A and D, let another circle *m* E *n* be alſo deſcribed, cutting the former ADE in E; then draw ABE for the perpendicular required. For, conceiving right lines to be drawn from C to A and E, the triangle ACE, is iſoſceles; alſo the angle ACE, being biſected by the line PQ, the angles ACB and BCE are equal, and therefore the angles at B are equal or right angles.

Prob. III. To biſect or divide into two equal parts, any given right lined angle PAQ (*fig*. 81.) In the lines containing the given angle, take AC = AD; and upon the centers C and D, with any equal radii, let two circles be deſcribed, ſo as to interſect each other; and from the point of interſection E draw EA, and the thing is done. For, let CD, CE, and DE, be drawn; then, the triangles ACD and ECD, being both iſoſceles, the angle ACD will be = ADC, and ECD = EDC; and conſequently the whole angle ACE = the whole angle ADE; whence (AC being = AD, and EC = ED) the angle CAE is alſo = the angle DAE.

☞ *As it would ſwell the Syſtem beyond the limits of our plan to give the demonſtration of every problem, we ſhall therefore, in the remaining problems, confine ourſelves to the conſtruction only.*

Prob. IV. To biſect a given right-line (AB); (*fig*. 82.) From the extremes A, B, of the given line, with equal radii, deſcribe two arcs, ſo as to cut each other; and between the two points of interſection draw CD, cutting AB in E; and the thing is done.

Cor. Here CD not only biſects AB, but is alſo perpendicular to it.

Prob. V. From a given point (A) in a given right-line (AQ) to draw a line (AK) which ſhall make with the former an angle, equal to an angle given (HBG) (*fig*. 83 and 84.) In BG and AQ take two equal diſtances BC, AD; and at C and D erect the two perpendiculars CI and DF to BG and AQ; and in DF take DE equal to the part CD of the former, intercepted by the lines containing the given angle HBG; then through E draw AEK, and the thing is done.

Prob. VI. To deſcribe a triangle, whoſe three ſides ſhall be equal to three given lines (A, B, C); provided any two of them, taken together, be greater than the third, (*fig*. 85.) Make FG = B, and from the centers F and G, with the intervals or diſtances A and C, let two circles DKL, HKL, be deſcribed; which will cut each other; and, if from the point of interſection K, the lines KF and KG be drawn, then will FKG be the triangle required.

Prob. VII. Through a given point (A), to draw a right-line (RS) parallel to a given right-line, (PQ); (*fig*. 86.) At any point B in the given line, make BC equal to the diſtance of the points A and B; and from the centers A and C, with an interval equal to CB, let two arcs be deſcribed, then through their interſection D, let the line RS be drawn, and the thing is done.

Prob. VIII. Upon a given line (AB) to deſcribe a ſquare, (ABCD), (*fig*. 87). Make AC perpendicular, and equal to AB; and from the centers B and C, let two arcs, with the radius AB or AC, be deſcribed, interſecting each other in D; from which point draw DB and DC, and it is done.

Prob. IX. To divide a given line (AB) into any propoſed number of equal parts, (*fig*. 88). From the extremes of the given line AB, draw two indefinite lines AP, BQ, parallel to each other; in each of which lines let there be taken as many equal diſtances AM, MN, NO, OC; B *o*, *o n*, *n m*, *m a*, (of any length at pleaſure) as you would have AB divided into; then draw M *m*, N *n*, O*o*, interſecting AB in E, F, G, and the thing is done.

Prob. X. To two given lines (AB, BC) to find a third proportional (*fig*. 89.) From any point A, draw two indefinite lines AP, AQ, in which take A*b* = AB, A*c* = BC, and *b*D = BC; draw *bc*, and parallel to *bc* draw DE, cutting AQ in E; then *c*E will be the third proportional required.

Prob. XI. To three given lines (AB, AC, BD) to find a fourth proportional, (*fig*. 90.) Having drawn AP and AQ, as in the preceding problem, take therein A*b* = AB, A*c* = AC, and *b*D = BD; draw *bc*, and parallel to it, draw DE, interſecting AQ in E; then is *c*E the fourth proportional required.

Prob. XII. Between two given lines (AB, BC) to find a mean proportional (*fig*. 91.) In the indefinite line AP, take A*b* = AB, and *b*C = BC; biſect AC in E, and from the center E, at the diſtance of EA, or EC, let a ſemicircle ADC be deſcribed; erect *b*D perpendicular to AC, cutting the circumference in D; then will *b*D be the mean-proportional required.

Prob. XIII. To divide a given line (AC) into two parts (AB, BC) having the ſame proportion as two given lines (AM, AN). (*fig*. 92.) From A draw AD, making any angle with AB; in which take A*m* = AM, and *mn* = MN; draw *n*C, and *m*B parallel thereto, meeting AC in B. Then will AB : BC : : A*m* (AM) : *mn* (MN).

Prob. XIV. To draw a tangent to a given circle (C) through a given point (A). (*fig*. 93, 94.)

Case I. If the given point be in the circumference; then, to the center C, draw AC, and perpendicular to AC draw BAD; which will touch the circle at A.

Case II. If the point A be without the circumference; then draw AC, which biſect in P; and from the center P, at the diſtance of AP, or CP, let a ſemi-circle AEC be deſcribed, cutting the given circle in E; then draw AED, which will be the tangent required.

Prob. XV. Upon a given line (PQ) to deſcribe a ſegment of a circle (PEQ) to contain an angle (E) equal to a given angle (BAC), (*fig*. 95 and 96.) Make AD perpendicular to AB; alſo make PQO, and QPO, each, equal to DAC (the difference between the given angle and a right one); then upon the point of interſection O, as a center, at the diſtance of OP (or OQ), let a circle be deſcribed; and the thing is done.

Scho. In the ſame manner the problem may be conſtructed, when the given angle is acute; only the lines PO, QO, muſt then be drawn on the other ſide of (PQ) as is manifeſt from the 9th theorem of the 3d Sect.

Prob. XVI. About a given triangle (ABC) to deſcribe a circle (*fig*. 97.) Let any two ſides, AB and AC, be biſected by two perpendiculars DF and EF; which will interſect each other in the center (F) of the required circle; from whence the circle may be deſcribed.

Scho. By the ſame method, the circumference of a circle may be deſcribed through any three given points, not ſituate in the ſame right line: alſo from hence, the center of a circle may be found, by having a ſegment of the circle given.

Prob. XVII. To inſcribe a circle in a given triangle (ABC). (*fig.* 98.) Biſect any two of the angles, A and B, by the lines AD and BD, meeting each other in D; make DE perpendicular to AB; then if from the center D, at the diſtance of DE, a circle be deſcribed, it will touch all the ſides of the triangle.

Prob. XVIII. In a given circle (AFB) to deſcribe a triangle, equiangular to a given triangle (PQR), (*fig.* 99, and 100). From the center C, draw the radii CA, CE, CB, making the angles ACE and BCE equal, each to the angle R; join A, B, and make the angle ABF = Q, and from the point F, where BF cuts the circle, draw FA; ſo ſhall AFB be the triangle required.

Prob. XIX. About a given circle (O), to deſcribe a triangle, equiangular to a given triangle (ABC), (*fig.* 101 and 102). Produce out the ſide AB both ways; and draw the radii OP, OR, OQ, ſo as to make the angle POR = EBC, and POQ = DAC; then draw three right lines to touch the circle in the points P, Q and R, and the thing is done.

Prob. XX. In a circle given (ABCD) to inſcribe a ſquare. (*fig.* 103.) Draw two diameters AC and BD perpendicular to each other; then draw AB, BC, CD and DA; ſo ſhall ABCD be a ſquare inſcribed in the circle.

Scholium. If two other diameters *ac*, *bd*, be drawn to biſect the angles AOB, BOC, a regular octagon A*a*B*b*C*c*D*d* may be inſcribed in the circle. And if all the angles at the center O, be again biſected, a regular poligon of ſixteen ſides, may in like manner be determined; and ſo on, at pleaſure.

Pro. XXI. In a circle given (ABGE) to inſcribe a regular pentagon, (*fig.* 104.) At the center O, upon the diameter FG, erect the perpendicular OB, meeting the circumference in B; divide OG in H, ſo that $OH^2 = GH \times OG$; that is, take $OR = \frac{1}{2}OF$, and RH = diſt. RB. Then draw BH; which will be equal to the ſide of the pentagon; from whence the figure itſelf may be deſcribed.

Scho. Hence a regular decagon may be inſcribed in the circle; the ſide thereof being = OH.

Prob. XXII. In a circle given, to inſcribe a regular hexagon (ABCDEF) (*fig.* 105.) From the extremes of any diameter AD, apply AB, AF, DC, and DE equal, each, to the radius AO; then join B, C, and E, F; and the thing is done.

Cor. Hence it appears, that the ſide of a regular hexagon, inſcribed in a circle, is equal to the ſemi-diameter, or radius.

Prob. XXIII. About a given circle to deſcribe a regular polygon, of the ſame number of ſides with a regular polygon (ABC DEF) inſcribed in the circle, (*fig.* 106) From the center O, to the angles of the inſcribed polygon, draw OA, OB, OC, &c. and perpendicular thereto draw PAQ, QBR, RCS, &c. interſecting in P, Q, R, S, T, V; ſo ſhall PQRSTV be the polygon that was to be deſcribed.

Prob. XXIV. To make a ſquare equal to a given rectangle (ABCD) (*fig* 107.) In one ſide AB of the rectangle, produced, take BE = the other ſide BC; biſect AE in O; and from the center O, at the diſtance of OA, or OE, let a ſemi-circle AFE be deſcribed; and let CB be produced to meet the circumference thereof in F; then a ſquare deſcribed on BF will be equal to the given rectangle ABCD.

Prob. XXV. To make a ſquare equal to the ſum of two given ſquares. Let AB and BC (*fig.* 108.) be the ſides of the two given ſquares. Draw two indefinite lines BP, BQ, at right angles to each other; in which take BA = BA, BC = BC, and join A, C; then a ſquare deſcribed on AC will be equal to the ſum of the two ſquares deſcribed upon AB and BC.

Scho. In the ſame manner a ſquare may be made equal to the ſum of three, or more, given ſquares: for if AB, BC, CE, be taken as the ſides of the given ſquares, then, by making BH = AC, BE = CE, and drawing EH, it is evident that a ſquare upon EH will be equal to the ſum of the three ſquares upon AB, BC, and CE.

Prob. XXVI. To make a ſquare equal to the difference of two given ſquares, (*fig.* 109.) Let AB and BC (taken in the ſame ſtrait line) be equal to the ſides of the two given ſquares. Upon the center B, with the radius BA, let a circle be deſcribed, and make CE perpendicular to BC, meeting the circumference thereof in E; ſo ſhall a ſquare deſcribed on CE be equal to BE^2 (BA^2) $-BC^2$.

Prob. XXVII. To make a triangle equal to a given quadrilateral (ABCD) (*fig.* 110.) Draw the diagonal AC, alſo draw DE parallel to AC, meeting BA produced in E, and join CE; then will the triangle BCE = the given quadrilateral ABCD.

Prob. XXIII. To make a triangle equal to a given pentagon (ABCDE) (*fig.* 111.) Draw DA and DB, and alſo EH and CF parallel to them, meeting AB produced in H and F; then draw DH and DF; ſo ſhall the triangle DHF = the pentagon ABCDE.

Prob. XXIX. Upon a given line (EF), to make a rectangle equal to a given triangle (ABC) (*fig.* 112 and 113.) From the vertex C, upon the baſe AB, let fall the perpendicular CD; make EH perpendicular to EF, and equal to a fourth proportional to 2EF, AB, and CD; then the rectangle EG contained under EF and EH will be equal to the triangle ABC.

Scho. By the preceding method, a parallelogram having a given angle may be deſcribed upon a given line, equal to a given triangle; if, inſtead of BDC, FEH, being right angles, you make them all equal to the angle given; the reſt of the conſtruction being the ſame.

Prob. XXX. Upon a given line (AB) to deſcribe a rectangle equal to a given right-lined figure (PQRS) (*fig.* 114, and 115.) Let the given figure be divided into triang. PQR, PRS: and upon the given line AB (by the precedent) let a rectangle ABDC, equal to the triangle PQR, be deſcribed; alſo upon CD make the rectangle CDFE equal to the triangle PRS; ſo ſhall ABEF, which is a rectangle, be = PQR + PRS = PQRS; which was to be done.

Prob. XXXI. To deſcribe a rectangle equal to the ſum or difference of two given right lined figures, (*fig.* 116 and 117.) Let the two given figures be ABN and P. By the precedent, let two rectangles AD and AF, reſpectively equal to ABN and P, be deſcribed on the ſame, or different ſides of AB; according as the difference, or ſum, of the two figures is required: then will the rectangle CF be equal to that ſum or difference.

Cor. Hence two lines having the ſame ratio with two given right-lined figures, are determined; for AC : AE : : AD (ABN) : AF (P) by Theorem 4, of Sect. 4.

Prob. XXXII. To make a ſquare equal to any right-lined figure given (ABCDF) (*fig.* 118.) Upon AB deſcribe a rectangle AE equal to ABC DF; then make a ſquare BH equal to that rectangle, and the thing is done.

Scholium. After the ſame manner a ſquare may be deſcribed equal to the ſum, or difference, of any two given right-lined figures.

Prob. XXXIII. To deſcribe a figure (FGHIK) equal, and ſimilar to a given right-lined figure (ABCDE) (*fig.* 119 and 120.) Draw AC and AD, and alſo FG equal to AB; make the angle GFH = BAC, HFI = CAD, and IFK = DAE; likewiſe make FH = AC, FI = AD, and FK = AE; then draw GH, HI, and IK, and the thing is done.

Prob. XXXIV. Upon a given line (AB) to deſcribe a figure (ABCDE) ſimilar to a given right-lined figure (PQRST) (*fig.* 121 and 122. Draw PR and PS, and in PQ (produced if needful) take P*q* = AB; draw *qr* parallel to QR, meeting PR in *r*; alſo draw *rs* and *st*, parallel to RS and ST, interſecting PS and PT in *s* and *t*; then upon AB, by the precedent, deſcribe a polygon equal and ſimilar to P*qrst*; and the thing is done.

Prob. XXXV. To deſcribe a figure, ſimilar to a right lined figure given (PQRST,) which ſhall be to it in a given ratio of one right-line to another, (*fig.* 123.) In PQ (produced if neceſſary) take P*n* to PQ in the given ratio of the figure to be deſcribed to the figure given; and, in the ſame line PQ, take P*q* equal to a mean-proportional between P*n* and PQ; upon which (by the precedent) let P*qrst*, ſimilar to PQRST, be deſcribed, and the thing is done.

Prob. XXXVI. To deſcribe a figure that ſhall be equal to one right-lined figure given (P,) and ſimilar to another (ABCD,) (*fig.* 124 and 125.) Upon AB make the rectangle ABFG = ABCD, and upon AG make the rectangle AGNE = P; in AB take AI equal to a mean proportional between AB and AE; and upon AI let AIKH be deſcribed ſimilar, and alike ſituate, to ABCD, and the thing is done.

SECT. VI. *Of the Interſection of Planes, &c.*

Definitions — 1. A right-line is ſaid to be perpendicular to a plane, when it is perpendicular to all right-lines, that can be drawn in that plane, from the point on which it inſiſts. 2. One plane is ſaid to be perpendicular to another, when all right-lines drawn in the one, perpendicular to the common ſection, are perpendicular to the other. 3. Parallel planes are thoſe, which are every where equally diſtant, the one from the other. 4. Similar ſolids are ſuch, as are bounded by an equal number of ſimilar planes.

Theorem I. The common ſection of two planes (AB, CD) is a right-line, (*fig.* 126.) For, between the two extreme points E, F, of the common ſection, let a right-line EF be drawn; then that line being in the plane AB and alſo in the plane CD, it muſt, of conſequence, be the common ſection of them both.

Theorem II. If a right-line (AB) be perpendicular to two other right-lines (CE, DF) cutting each other, at the common ſection (A), it will be perpendicular to the plane (CDEF) paſſing by thoſe two lines (*fig.* 127.) Take AC, AD, AE, AF, all equal to one another; and, having joined CD, DE, EF, CF, let there be drawn through A, in the plane CDEF, any right-line GH, meeting CF and DE in G, and H; and let BC, BG, BF, BD, BH, and BE be alſo joined. Becauſe AC = AE = AD = AF, and CAF = DAE, therefore is CF = DE, and the angle FCA (or GCA) = DEA or (HEA); and ſo, GAC being likewiſe = HAE and AC = AE, thence will AG = AH, and GC = HE. Again, ſince the right-angled triangles CAB, DAB, EAB, FAB have their baſes all equal, and the perpendicular AB common, their hypothenuſes BC, BD, BE, BF will be equal too; and therefore the triangles CBF, DBE, being mutually equilateral, the angle FCB (or GCB) muſt be = DEB (or HEB); whence, GC being alſo = HE, and BC = BE, thence is BG = BH: Therefore, AG being likewiſe (as is proved above) = AH, and AB common, the angles GAB, HAB, are equal, and conſequently right-angles. In the ſame manner, AB is perpendicular to every other right line drawn through A in the plane CDEF; which was to be demonſtrated.

Cor. Hence if one right line meeting ſeveral others in the ſame point is perpendicular to them all; theſe laſt will be all in the ſame plane.

Theorem III. If through any given point (A) in a given plane (BCD,) a line (CD) be drawn, and perpendicular to that line, at the ſame point (A) two other lines (AB, AE) be alſo drawn, the one (AB) in the plane given (BCD), and the other in any other plane (CDE) paſſing by the firſt line (CD); then, I ſay, that a right line (AF) drawn from the given point (A), at right angles to the firſt perpendicular (AB) in the plane (BAE of the two, will be perpendicular to the given plane (BCD) at the given point (A) (*fig.* 128.) For CA being perpendicular both to AB and AE, it will likewiſe be perpendicular to AF, by the laſt theorem; and ſo FA, being perpendicular to AB (as well as to CA) is alſo perpendicular to the plane BCD, in which AB and CA are drawn.

The. IV. Two right lines (AB, CD), perpendicular to the ſame plane (EF), are parallel to each other, *fig.* 129. Draw in the plane EF, the right line AD, and alſo DG perpendicular to AD; make DG = AB, and let AG, BG, and BD be drawn. The triangles BAD, ADG, having AB = DG, AD common, and the angle BAD (= right-angle = ADG,) will alſo have BD = AG; and ſo, the triangles BDG, BAG, being mutually equilateral, the angle BDG muſt be = BAG = right angle. But the line CD (as well as BD and AD) being perpendicular to DG, it is therefore in the ſame plane (CDAB) with BD and AD, by Cor. to Theorem 2, of this ſection; and conſequently, as the angles BAD, CDA, are both right-ones, it muſt be alſo parallel to BA.

Cor. I. Hence it follows, that from the ſame given point, to one and the ſame plane, more than one perpendicular right-line cannot poſſibly be drawn: becauſe all perpendiculars to the ſame plane, are parallels; but lines drawn from the ſame point are not parallels.

Cor. II. If, of two parallel right-lines the one is perpendicular to any plane, the other ſhall alſo be perpendicular to the ſame plane.

Theorem V. If a right-line (PQ) be perpendicular to plane (AB), any plane (ED) paſſing by that line, will be perpendicular to the ſame plane (AB), (*fig.* 130.) In the plane ED, from any point K, draw KI perpendicular to the common ſection CD. Then, the angle DIK being a right angle = DQP, IK, will be parallel to PQ, and therefore perpendicular to the plane AB by Cor. 2 to Theo. 4. of this ſection. By the ſame inference, all other right-lines drawn in the plane ED, perpendicular to the common ſection CD, are alſo perpendicular to the plane AB. Therefore the plane ED itſelf is perpendicular to the plane AB.

Cor. I. Hence the plane AB, is perpendicular to the plane ED.

Cor. II. Hence alſo a line ſtanding at right-angles to one of two perpendicular planes at any point (I) in the common ſection (CD) muſt be in the other plane

Theorem VI. Planes (EF, GH) to which one and the ſame right line (AB) is perpendicular, are parallel to each other, *fig.* 131.

From any point C, in the plane EF, let CD be drawn parallel to AB; which, as well as AB, will be perpendicular to both the planes by Cor. 2, to Theor. 4 of this ſection; and ſo the angles A, B, C, D (when AC and BD are joined) being all right-ones, the figure ABCD (whereof the ſides AC, BD, are in the ſame plane with the parallels AB, CD) will therefore be a rectangular parallelogram; and conſequently CD = AB. By the very ſame argument, all other perpendiculars, terminated by the two planes, are equal among themſelves; which was to be demonſtrated.

Cor. Hence, all right-lines perpendicular to one of two parallel planes, are alſo perpendicular to the other.

Theorem VII. Right lines (AB, CD) parallel to one and the ſame right-line (EF), though not in the ſame plane with it, are alſo parallel to each other (*fig.* 132.) Let GH and GI be drawn perpendicular to EF, in the planes AF and ED of the propoſed parallels. Then by Theorem 2 of this ſection ſhall GF be perpendicular to the plane paſſing by HGI; and HB, ID, will alſo be perpendicular to the ſame plane and therefore parallel to each other by Theorem 4. Cor. 2.

Theo. VIII. If two right lines (AB, AC) meeting each other, be reſpectively parallel to two other right-lines (DE, DF) alſo meeting each other, and not being in the ſame plane with them; the angles (BAC, EDF) contained by thoſe lines, will be equal, (*fig.* 133.) Take AB, AC, DE, DF, all equal to each other, and let BE, AD, CF, BC, EF, be drawn. Then, AB and ED, as well as AC and DF, being equal, and parallel, BE and CF will be both equal and parallel to AD; and therefore equal and parallel to each other by the laſt Theorem, and Axiom 1; whence BC is alſo equal to EF; and ſo, the triangles ABC, DEF, being mutually equilateral, the angles BAC, EDF, are likewiſe equal.

Theorem IX. If two right angles (AB, AC) meeting each other, be reſpectively parallel to two other right-lines (DE, DF) alſo meeting each other, and not being in the ſame plane with them, the planes (BAC, EDF) extended by thoſe lines, will be parallels, (*fig.* 134.) Let AG be perpendicular to the plane BAC, meeting the plane EDF in G; in which laſt plane, let GH and GI be drawn parallel to ED and DF; and they will alſo be parallel to AB and AC, by Theorem 7 of this ſection; whence, ſeeing the angles GAB and GAC are both right, AGH and AGI muſt likewiſe be right-angles; and ſo AG being perpendicular to the plane EDF by Theorem 2 of this ſection, (as well as to BAC), the two planes are parallel to each other by Theorem 6.

Theorem X. The ſections (EF, GH) made by a plane (EFHG) cutting two parallel planes (AB, CD) are alſo parallel, the one to the other, (*fig.* 135.) Let EG and FH be drawn parallel to each other, in the plane EFHG; alſo let EI, FK, be perpendicular to the plane CD, and let IG, KH be joined; then, EG being parallel to FH, and EI to FK, the angle GEI by Theorem 8 of this ſection, is = HFK; but the angle EIG is alſo = FKH, being both right-angles; and EI is = FK; therefore EG will be equal (as well as parallel) to FH; and conſequently EF likewiſe parallel to GH.

Cor. It appears from hence, that parallel lines, terminated by the ſame parallel planes, are equal to each other.

Theorem XI. If from the two extremes of a right-line (AB cutting a plane, CD), two perpendiculars (AF, BG) be drawn to the plane; the right line (FG) joining the points where they meet the plane, will paſs through the point (E) in which the propoſed line (AB) cuts the plane, ſo as to be divided by it into two parts (FE, EG), having the ſame ratio to each other as thoſe two perpendiculars (AF, BG) *fig.* 136. For, if AF be produced to *f*, the lines A*f* and BG (which are both perpendicular to the plane CD) will be parallel to each other; therefore A B and FG being both in the ſame plane with theſe parallels, in which their extremes are poſited, they muſt neceſſarily (as they are not themſelves parallels) interſect each other; and ſo the alternate angles FAE, GBE being equal, as well as the oppoſite ones FEA, GEB, thence will FE : EG :: AF : BG; which was to be demonſtrated.

Cor. Hence, if in the plane CD, the lines FC, GD, be made parallel, the one to the other, and in them be taken F*a* = FA, and G*b* = GB; then will the line (*ab*) joining the points *a* and *b*, cut FG in the very ſame point in which it is cut by AB. For, if *e* be taken as the interſection of *ab* and FG, the triangles *a*F*e*, G*eb* will be equiangular; whence by Theory 8 of ſection 4, and the preceding theorem, F*e* : *e* G :: F*a* (FA,) G*b* (GB) :: FE : EG. Therefore, ſeeing FG is divided in one and the ſame ratio, both by *e* and E, theſe points muſt neceſſarily coincide.

Theorem XII. If two planes (AB, CD) cutting each other, be both perpendicular to a third plane (GH), their common ſection will alſo be perpendicular to the ſame plane (GH). (*fig.* 137.)

For from the extreme point F of the common ſection, let the right line FE be erected perpendicular to the plane GH, which line being in both the planes, AB, and CD, (by Cor. 2, of Theorem 5 of this ſection) it muſt neceſſarily be their common ſection. Therefore from the conſtruction the common ſection is perpendicular to the plane GH.

N. B. The theorems introduced in this ſection have been thought ſufficient in this place. Other propoſitions pertaining to the relative magnitude of ſolids will be given in the ſyſtem of Menſuration.

PART II. CONIC SECTIONS.

Genesis.

1. If a right cone, ABC, be cut into two parts by the plane LDG, (Plate II. *fig.* 1.) parallel to one of its ſides, as AB, the ſection LDG, will be a curve, called a parabola. 2. If any cone, as ABC, (*fig.* 2) be cut by a plane paſſing through both its ſides, and not parallel to the baſe BC, the ſection BNDK, will be a curve, named an elipſes, or oval. 3. If a cone, MDN, (*fig.* 3.) be cut by a plane parallel to any plane, DXY within the cone, which paſſes through the vertex D; the ſection LAT, will be a curve called an hyperbola. Alſo, if a cone were cut by a plane paſſing through the vertex and the centre of the baſe, the ſection would be a triangle; or if cut by a plane, parallel to the baſe, the ſection would be a circle. But as the triangle is a plain right lined figure, and the circle is ſimply deſcribed by the rotation of a right line round a point, the parabola, elipſes, and hyperbola, are the only figures that bear the name of conic ſections; for though the circle is not a right lined figure, yet on account of the ſimplicity of its geneſis, it has been ever treated of under plain geometry. And the conic ſections themſelves may be generated *in plano*, independent of the cone; which alſo affords the eaſieſt and ſimpleſt methods of demonſtrat ing their ſeveral properties. I ſhall therefore conſider them in thi light, and treat of each in due order.

SECT. I. OF THE PARABOLA.

Definitions. 1. If one end of a thread equal in length t CH (*fig.* 4.) be fixed at the point F, and the other end fixed at H the end of the ſquare DCH; and if the ſide (CD) of the ſqua be moved along the right line BD, and do always coincide wi it; and further, if the ſtring FGH, be always kept tight, an cloſe to the ſide (GH) of the ſquare, then the point or pin G (where it leaves the ſquare) will deſcribe a parabola MRALGK 2. The fixed point F, is called the focus. 3. The right line B is named the directrix. 4. If the right line BN, be drawn throu the focus F, perpendicular to BD, then AN is called the axis, a A, the vertex of the parabola. 5. A line drawn through the f cus F, perpendicular to the axis, as LR is named the *parameter* *latus rectum*. 6. Any line drawn within the curve, parallel to t axis, as GH is named a diameter; and the point G, where cu cuts the curve, is the vertex. 7. A right line meeting the curve in any point G, but not cutting the ſame, is called a tangent in that point. 8. A right line drawn from any diameter to the curve and parallel, to the tangent at the vertex, as PM, is called an ordinate. If it go quite through the curve, it is named a double ordinate. 9. The part of the diameter between the vertex and ordinate, as GP, is named the abſciſſa.

Prop. I. If G be any point in the curve, the line GC, drawn to the directrix BD, parallel to the axis, is equal to the line FG, drawn from the ſame point to the focus. For $HG + GF =$ length of ſtring $= HD$; and taking away GH from both, there remains $GD = GF$.

Cor. I. Hence the diſtances of the focus, and the directrix from the vertex are equal.

Cor. II. If GP, be an ordinate to the axis, then $AP + AF = FG$.

Cor. III. $FG - FP =$ half the latus rectum.

Prop. II. The diſtance of the focus, or the directrix from the vertex is $\frac{1}{4}$ the latus rectum, viz. AF (or AB) $= \frac{1}{4} LR = \frac{1}{2} LF$. For, when the pin G, comes to L, then $LF = FB$ (= by Prop. 1. Cor. 1.) $2FA$, and $AF = \frac{1}{2} FL$. Alſo $FA = \frac{1}{2} FR$, and conſequently $FA = \frac{1}{4} LR$. Scholium, In any other diameter GH, four times the diſtance of its vertex from the focus, is called its latus rectum.

Prop. III. The ſquare of any ordinate to the axis, is equal to the rectangle of the latus rectum, and abſciſſa, viz. $GM^2 = LR \times AP$. Demonſtration, by Prop. 1. Cor. 2. $GF = AF + AP =$ (Prop. 2.) $AP + \frac{1}{4} LR$, and $FP = AP - AF = AP - \frac{1}{4} LR$. And in the *right angle triangle*, GFP, $GP^2 = GF^2 - FP^2 = \overline{GF + FP} \times \overline{GF - FP} = 2AP \times \frac{1}{2} LR = AP \times LR$.

Cor I. If F is the focus, $GP^2 = AP \times 4AF$.

Cor. II. The abſciſſas are as the ſquares of the ordinates, viz. $AP : AN :: GP^2 : NM^2$. For, $AP : AN :: AP \times LR : AN \times LR$; and therefore, as GP^2 to $NM^2 = NK^2$.

Cor. III. The latus rectum, is a third proportional to the abſciſſa and ordinate.

Prop. IV. As the latus rectum (RL) is to the ſum of any two ordinates (as $GP + NM$ ($= HN + NM$) ſo is their difference $NM - GP$ ($= HK$) to the difference of the abſciſſa, PN.

Demonst. By Prop. III. $LR \times AP = GP^2$, and $LR \times AN = NK^2$; and, by ſubtraction, $\overline{LR \times AN} - \overline{LR \times AP} = NK^2 - PG^2$. Therefore, $LR : NK + PG :: NK - PG : AN$, viz. $LR : HM :: HK : PN$.

Cor. I. If GH be the axis, KM, an ordinate to it, then the rectangle $KH \times HM = GH \times$ parameter.

Cor. II. The rectangle $KH \times HM$ is every where as GH.

Prop. V. If a line AN, (*fig.* 5.) be drawn from the vertex, to cut the curve in M, and the ordinate QO in N; and the ordinate PM, being likewiſe drawn, then will the rectangle $PM \times QN = AQ \times$ parameter. For, let $L =$ latus rectum, then (by Prop. 3. $QO^2 = L \times AQ$ and (by Cor. 2. of the ſame) $PM^2 : QO^2$ or $L \times AQ :: AP : AQ$: and by ſimilar triangles $:: PM : QN$; and $PM^2 \times QN = PM \times L \times AQ$, or $PM \times QN = L \times AQ$.

Cor. I. $PM \times QN = QO^2$.

Cor. II. Any line beſide the axis, paſſing through the vertex A, will cut the curve again in ſome point M.

Prop. VI. If from any point C, in the axis, the line CF be drawn, cutting the curve in D and F, and alſo the ordinates, DB and FQ. Then $CA^2 = AB \times AQ$. For, by Prop. 3. Cor. 2. $Ab : AQ :: BD^2 : QF^2$; and by ſimilar triangles $:: \overline{CA + AB}^2 : \overline{CA + AQ}^2$; whence $AB \times \overline{CA^2 + 2CA \times AQ + AQ^2} = AQ \times \overline{CA^2 + 2CA \times AB + AB^2}$, and $AB \times CA^2 + AQ^2 = AQ \times \overline{CA^2 + AB^2}$; therefore $\overline{AQ - AB} \times CA^2 = AQ^2 \times AB - AB^2 \times AQ = \overline{AQ - AB} \times AQ \times AB$. Conſequently $CA^2 = AQ \times AB$.

Prop. VII. If AB (*fig.* 6,) be perpendicular to the axis AE; and if EG be an ordinate and AG be drawn. Then any line BF being drawn parallel to the axis AE, cutting the curve in M, and EG in F, the lines BM, BD, and BF, will be in continued proportion. For (by Prop. 3, Cor. 2) $AP : AE :: PM^2$ or $CD^2 : EG^2$; and by ſimilar triangles $:: AC^2 : AE^2$; conſequently $AP : AC :: AC :: AE$; that is $BM : BD :: DD : BF$.

Prop. VIII. If from any point in the curve, as M (*fig.* 7.) a line be drawn to the focus, as MF; and if MD be drawn parallel to the axis, cutting the directrix BD in D, and DF be joined; then the line MG drawn through the middle of DF will touch the curve in M. Demonſtration. From any other point *m* in the line MG, draw MF to the focus, and *md* perpendicular to BD; then ſince $MF = MD$, and $mF = mD$, the triangles FMD and F*m*D are iſoceles, and $FG = GD$; but the angle D*dm* being right, D*m*, or *m*F is greater than *dm*; therefore the point *m*, by the generation of the parabola is without the curve.

Cor. I. If the tangent MD be continued to cut the axis at T, the diſtance of the focus and interſection is equal to the diſtance of the focus and point of contact, viz. $FT = FM$.

Cor. II. The tangent MG biſects the angle DMF, made by the line perpendicular to the directrix, and that drawn to the focus.

Cor. III. A line drawn from any point M to the focus, parallel to the axis, make equal angles with the curve, viz. $FMm = OMr$.

As it is incompatible with the bulk and nature of this work to lay down the demonſtration of every truth we advance, and as it is only the propoſitions, or properties of the curves, that are wanted in uſeful occurrences, we judge it will be more acceptable to our readers to ſuppreſs many of the demonſtrations, than to omit informing them of thoſe propoſitions and properties, which may ſerve as rules or theorems for reſolving many practical matters; thoſe who are curious in demonſtrations may exerciſe themſelves therein; and if they have attained a tolerable knowledge in plain geometry, and trigonometry, and have a perfect underſtanding of thoſe demonſtrations that are given, they will not find much difficulty in demonſtrating the remaining propoſitions.

Prop. IX. If the tangent at M cut the axis AB at T, then the diſtance of the interſection from the vertex (AT) $=$ AP, the abſciſſa to the ordinate PM. From this propoſition are alſo derived the following Corollaries.

Cor. I. The ſubtangent PT is double the abſciſſa AP.

Cor. II. The tangent at the vertex A is perpendicular to the Axis AB.

Cor. III. All parabolas having the ſame abſciſſa will have their tangents meeting in the ſame point of the axis.

Prop. X. If two parabolas be deſcribed on the ſame axis, the ordinates will be proportional, or in a given ratio. This is eaſily demonſtrated from Prop. 3, and alſo this following Corollary, viz. The correſpondent ordinates of two parabolas deſcribed on the ſame axis, are in the ſubduplicate ratio of the parameters.

Prop. XI. If F be the focus, MR, perpendicular to the tangent MT, then the ſubnormal (PR) or diſtance of the ordinate from the point of interſection $=$ half the latus rectum.

Cor I. $FT = FM = FR$; and a circle deſcribed with the radius FM, and centre F, will paſs through T, M and R.

Cor. II. The angle MFR is double the angle MTR.

Cor. III. If RS be perpendicular to MF; then $MS =$ half the latus rectum.

Cor. IV. Hence $MS = RP = 2\,AF = \frac{1}{2}$ parameter.

Prop. XII. If MT be a tangent at any point M, AG a tangent at the vertex; and if FG be perpendicular to MT, from the focus, it will paſs through the interſection G.

Cor. I. If MP, be an ordinate, then will $AG^2 = AP \times \frac{1}{4}$ latus rectum, $= AG^2 \times AF$.

Cor. II. $AG =$ half the ordinate MP.

Cor. III. FA, FG, and FM, are in continued proportion.

Prop. XIII. If F be the focus, MR perpendicular to the curve at M, then $RM^2 = RF \times$ latus rectum.

Prop. XIV. If FH be an ordinate at the focus (*fig.* 7.) FHG a tangent at H, PM an ordinate continued to the tangent at G, then $TP = FM = PG$.

Cor. If AL be a tangent at the vertex, then $TA = AL = AF = \frac{1}{4}$ parameter; and $TF = FH = \frac{1}{2}$ parameter.

Prop. XV. In any diameter as MK (*fig.* 8,) the abſciſſas are as the ſquares of the ordinates, viz. $ML : MK :: LQ^2 : KG^2$.

Cor. Any diameter interſects the curve only in one point, viz. in the vertex to the diameter.

Prop. XVI. In any diameter as FH (*fig.* 8.) the ſquare of any ordinate (LQ) is equal to the rectangle of its parameter, and the abſciſſa ML.

Cor. I. The parameter is a third proportional to the abſciſſa and ordinate.

Cor. II. If MP be perpendicular to the axis AP, then the latus rectum of the diameter ML, exceeds the latus rectum of the axis by $4AP$.

Cor. III. If MC is perpendicular to the tangent MT, then $TC = \frac{1}{2}$ latus rectum of the diameter ML.

Cor. IV. The line GC (*fig.* 4) perpendicular to the directrix $BD = \frac{1}{4}$ of the latus rectum of the diameter GH.

Prop. XVII. In any diameter, the whole ordinate paſſing through the focus, is the latus rectum to that diameter, and is equal to four times its abſciſſa.

Cor. I. The abſciſſa in ſuch caſe is equal to the diſtance of the focus from the vertex.

Cor. II. The rectangle of the two parts of the whole ordinate intercepted between the focus and the curve, is equal to the rectangle of half the whole ordinate by half the parameter.

Prop. XVIII. If MK (*fig.* 8.) be any diameter, and DL be an ordinate to it, and DK perpendicular to it, then $DK^2 = ML \times$ latus rectum of the axis.

Cor. I. The ſquares of the perpendiculars DK, are as the abſciſſas ML.

Cor. II. If from the vertices M, G, of two diameters, MK and QV, two ordinates be drawn, QL and MV, then the abſciſſas MK and QV, will be equal.

Prop. XIX. If from any point M, a tangent be drawn, to cut any diameter QV, in N, (*fig.* 8.) and the ordinate MV be drawn, then the diſtance QN, from the interſection to the vertex, is equal to the abſciſſa QV.

Cor. I. The ſubtangent VN, is double the abſciſſa QV.

Prop. XX. If BD, be a directrix, (*fig.* 9.) GL, any diameter, ML, an ordinate, MT, a tangent, MK, perpendicular to GL, then the ſquare of the tangent (MT^2) is to the ſquare of the ordinate, (ML^2) as the diſtance of the point of contact from the directrix (MD) to $\frac{1}{4}$ the latus rectum of GL. From this propoſition are deduced the following corollaries. 1. If the diameter GL, becomes the axis, then the ſquare of the tangent (MT^2) is to the ſquare of the ordinate (MP^2) as $AF + AP$ to AF, that is as the latus rectum of MK, to the latus rectum of the axis. 2. The ſquare of the tangent MT, is to the ſquare of the perpendicular MK, as the diſtance of the point of contact and directrix MD, $\frac{1}{4}$ the parameter of the axis AB. 3. $ML^2 : MK^2 :: FG : AB$. 4. $LK^2 = 4HG \times GL$. 5. $MT^2 =$ rectangle $4FK \times GL$.

Prop. XXI. If any diameter interſect two parallel lines, the rectangle of the ſegments of the lines will be as the ſegments of the diameter, viz. in (*fig.* 8.) $DL \times LQ : RK \times KG :: ML : MK$.

Cor. If any line RG, be cu tby two diameters, QX and AS, the rectangle of the parts are as the ſegments of the diameters, viz. $RX \times XG : RS \times SG :: QX : AS$.

Prop. XXII. In any diameter, as its latus rectum, is to the ſum of any two ordinates, ſo is their difference to the difference of the abſciſſas.

Prop XXIII. *fig.* 10. If AC be a tangent at A, AH any line drawn within the parabola, DF any diameter, cutting the tangent in B, and the line AH in F, then $AF : FH :: BD : DF$.

Cor. I. If LG be any diameter, AH an ordinate; AC a tangent at A; HC parallel to GL, then $AH^2 = HC \times$ parameter of LG, alſo $HC = 4LG$; and $AF^2 = BD \times$ parameter of LG.

Prop. XXIV. If any circle, cut a parabola in four points, and from the points of interſection ordinates be drawn to the axis, the ſum of the ordinates, or one ſide of the axis, is equal to the ſum of the ordinates on the other.

Prop. XXV. If LC, NC, DF, (*fig.* 11.) be three tangents, at LN and A, then will $DA : AF :: LD : DC :: CF : FN$.

Prop. XXVI. All parabolas are ſimilar figures, and therefore if their parabolas have their parameters and abſciſſas equal, they will be both equal and ſimilar.

Prop. XXVII. Two equal parabolas upon the ſame axis, but havihg different vertices, approach infinitely near one another, but never meet.

PROBLEMS RELATING TO THE PARABOLA.

Prob. I. To deſcribe a parabola by local motion. This is done by Definition I.

Prob. II. The axis and parameter being given to deſcribe the parabola, (*fig.* 12.) Let AC be the axis, make $AF = AB = \frac{1}{4}$ latus rectum. Draw KCL perpendicular to AC. From the center F with the radius BC, cut KL in K and L, which are the points of the curve; and the like for more points.

Prob. III. Any diameter in a parabola being given to draw an ordinate from a given point in the curve. Let AB (*fig.* 13) be the diameter, H the given point; through H draw HC parallel to AB; and at the ſame diſtance from AB on the other ſide, draw DL parallel to AB, to cut the curve in L; then draw HL, which will be a double ordinate to AB.

Prob. IV. To any given point M of a parabola, (*fig.* 14) to draw a tangent. From the given point M draw MG parallel to the axis AB, and make $MG = MF$. Draw GF, and biſect it in D, and draw DM for the tangent at M.

Prop. V. The focus F of a parabola being given, (*fig.* 15) and three points in the curve M, N, P, to deſcribe the parabola. Through NM and alſo NP, draw the lines NK and NI; and draw MF, NF, PF, to the focus. Then make $FN : FM :: NK : MK$; and $FN : FP :: NI : PI$. Through K and I draw the line KI, and FT perpendicular to it from the focus; biſect FT in A, for the vertex; then with the focus F, and directrix IK, deſcribe a parabola through the point M (by Prob. 2), which will paſs through the points NP.

SECT. II. OF THE ELLIPSES.

Definitions. 1. If two pins be fixed at the points F and S (*fig.* 16;) and if a thread PSFP, be put about them and knotted at P, and if the ſame be drawn tight, and the point P and the thread be moved about the fixed centres F, S, the point P will deſcribe the curve PD*p*BEAP, called an ellipſes. 2. The points or centres F and S are named the *foci*. 3. The line AB drawn through the foci to the curve, is called the *tranſverſe axis*. 4. The point C in the middle of the axis AB is the centre. 5. The line DE (drawn through the centre C) perpendicular to the tranſverſe axis, is called the *conjugate axis*. 6. Any line (TO) (*fig.* 17.) drawn through the centre C to the curve, is named a *diameter*, and the extremity T (or O) its vertex. 7. If TO be a diameter, then the diameter GK drawn parallel to the tangent at its vertex T is named its *conjugate*, and the two diameters TO, and GK are ſaid to be conjugates to one another. 8. The line LR drawn through the focus F perpendicular to the tranſverſe axis AB, is called the *parameter*, or latus rectum. 9. A line drawn from any point of the curve, as HI perpendicular to the tranſverſe axis, is called an ordinate to the tranſverſe; and in general, any line drawn from the curve to any diameter TO parallel to its conjugate GK (as HN) is an ordinate to that principal diameter TO. If it go quite through the figure as H *h*, it is called a double ordinate. 10. A right line meeting the ellipſes in one point, M, but which does not cut the ſame, is named a tangent, to it in that point, as TM. 11. The part of the diameter between the vertex, and the ordinate, is named the *abſciſſa*.

Prop. I. FP, SP, drawn from the foci to any point of the curve is equal to the tranſverſe axis AP, (*fig.* 16.) For by conſtruction $PF + PS = AF + AS = AF + AF + FS = 2AF + FS$. And the ſame $PF + PS = 2BS + FS$. Therefore $2AF + FS = 2BS + FS$, and $2AF = 2BS$ or $AF = BS$; whence $PF + PS = 2AF + FS = AF + BS + FS = AB$.

Cor. The two foci are equally diſtant from the vertices, and alſo equally diſtant from the centre.

Prop. II. A line drawn from the end of the conjugate axis to the focus, is equal to half the tranſverſe, viz. $DF = AC$ (*fig.* 16.) Draw DS to the other focus, then the two triangles CDF and CDS are equal and ſimilar; for $SC = CF$, the angles at C are right, and CD is common; and conſequent $SD = DF$ and as their ſum $(SD + DF) =$ the tranſverſe by the laſt propoſition, one of them $DF =$ half the tranſverſe CA.

Cor. the diſtance of the foci is a mean proportional between the ſum and difference of the tranſverſe and conjugate axes.

Prop. III. The rectangle of the focal diſtances from either vertex, is equal to the ſquare of the ſemi-conjugate, $AF \times FB = DC^2$. For $DC^2 = DF^2 - CF^2 =$ (by Prop. 2.) $CA^2 - CF^2 = \overline{CA + CF} \times \overline{CA - CF}$, by Theorem V. Sect. II. of Plain Geometry $= \overline{BC + CF} \times \overline{CA - CF} = BF \times FA$.

Prop. IV. As the tranſverſe axis is to the conjugate ſo is the conjugate to the latus rectum of the tranſverſe, viz. $AB : DE :: DE : LR$. For $SL + LF = BA = 2CA$ (Prop. 1.) and $SL = 2CA - LF$, and by ſquaring, $SL^2 = 4CA^2 - 4CA \times LF + LF^2$. And in the right angled triangle SLF $+ SL^2 = SF^2 + LF^2$; whence $4AC^2 - 4CA \times LF = SF^2 = 4CF^2$, and $4AC^2 = 4CA \times LF + 4CF^2 = 4CA \times LF + 4DF^2 - 4DC^2$; and $4AC^2 + 4DC^2 = 4CA \times LF + 4DF^2$; but $CA^2 = DF^2$ (by Prop. 2.); therefore $4DC^2 = 4CA \times LF = 2CA \times 2LF$; that is $DE^2 = BA \times LR$.

Cor. I. As the ſemi-tranſverſe is to the ſemi-conjugate, ſo is the ſemi-conjugate to half the latus rectum, viz. $CA : DC :: DC : LF$.

Cor. II. As the ſemitranſverſe is to the diſtance of the focus from the centre, ſo is the ſame diſtance to the difference between the ſemitranſverſe, and half the latus rectum, viz. $FC^2 = CA \times \overline{CA - LF}$.

Cor. III. The rectangle $BFA =$ half the tranſverſe $\times$ half the latus rectum $= CA \times FL$.

Schol. Since the tranſverſe axis is to the conjugate, as the conjugate is to the latus rectum of the tranſverſe axis; therefore in any other diameters, the third proportional to the diameter and its conjugate is called the *latus rectum* of that diameter.

Prop. V. From any point M in the curve, (*fig.* 18) if the lines to the foci MF and MS be drawn, and the ordinate MP, perpendicular to the axis BA, it will be as the ſemitranſverſe (CA) is to the diſtance of the focus from the centre (CF), ſo is the diſtance of the ordinate from the centre (CP) to half the difference of the lines MF and MS; or to $\frac{MS - MF}{2}$.

For make $SD = CA$, then $SM = CA + DM$ and $FM = 2CA - SM = CA - DM$. In the right angled triangle SMP, SM^2, or $CA^2 + 2CA \times DM + DM^2 = SP^2 + PM^2 = \overline{CF + CP}|^2\ PM^2 = CF^2 + 2CF \times CP + CP^2 + PM^2$, and in the right angled triangle FMP, FM^2 or $CA^2 - 2CA \times DM + DM^2 = FP^2 + PM^2 = \overline{CF - CP}|^2 + PM^2 = CF^2 - 2CF \times CP + CP^2 + PM^2$; and ſubtracting the latter equation from the former $SM^2 - FM^2 = 4CA \times DM = 4CF \times CP$, and $CF \times CP = CA \times DM$. But ſince $SM = CA + DM$, and $FM = CA - DM$; therefore $SM - FM = 2DM$, and conſequently $CF \times CP = CA \times \frac{SM - FM}{2}$.

Cor. I. If F, S, be the foci, MP an ordinate, then it is as $CA : CF :: CP : \overline{CA - MF}$ or $\overline{SM - CA}$.

Cor. II. If F, S, be the foci, MP an ordinate, then the difference of the ſquares of the lines SM and FM, viz. $SM^2 - FM^2 = 4CF \times CP$.

Cor. III. $CA \times \overline{SM - FM} = 2CF \times CP$.

For the ſake of enumerating the more propoſitions and properties of the ellipſis, in what follows the demonſtrations are ſuppreſſed.

Prop. VI. If an ordinate (MP) be drawn to the tranſverſe axis, (*fig.* 18.) it will be as the ſquare of the tranſverſe (BA^2) is to the ſquare of the conjugate (NE^2) ſo is the rectangle of the ſegments of the tranſverſe ($BP \times PA$) to the ſquare of the ordinate. (PM^2)

Cor. I. $CA^2 : CN^2 :: BF \times FA : PM^2$.

Cor. II. As the tranſverſe BA : to its latus rectum :: rectangle $BP \times PA$: the ſquare of the ordinate or PM^2.

Cor. III. The rectangles of the ſegments of the tranſverſe are as the ſquares of the ordinates.

Cor. IV. As the ſquare of the ſemitranſverſe (CA^2) rectangle of the focal diſtances from the vertex ($BF \times FA$) :: rectangle of the ſegments ($BP \times PA$) : ſquare of the ordinate (PM^2).

Prop. VII. If the ordinate MG (*fig.* 18) be drawn perpendicular to the conjugate NE, it will be as the ſquare of the ſemiconjugate : ſquare of the ſemitranſverſe :: rectangle of the ſegments of conjugate $NG \times GE$ to the ſquare of the ordinate MG; or MG^2.

Cor. The whole ordinate to the tranſverſe or conjugate axis is biſected by that axis, and equal ordinates are equally diſtant from the centre.

Prop. VIII. If MP be ordinate to the tranſverſe (*fig.* 18) F, S, the foci, and if CA be to CF as CP to CI, then the rectangle $SM \times MF = CA^2 - CI^2$.

Cor. I. If $CA : CF :: CP : CI$, then $FM = AI$ and $SM = BI$.

Cor. II. $CA : CF :: CP : CA - FM$ or $SM - CA$.

Prop. IX. If MP be an ordinate to the tranſverſe as before, then $CM^2 = CA^2 + CE^2 - SM \times MF$.

Cor. I. If $CA : CF :: CP : CI$, then $CM = EI$, and the rectangle $BP \times PA =$ rectangle $SI \times IF + PM^2$.

Prop. X. (*fig.* 18.) The lines SM and FM drawn from the foci to any point M in the curve, make equal angles with the curve in that point.

Cor. If a line MO be drawn perpendicular to the tanges MT in M, the angles FMO and SMO are equal.

Prop. XI. If MP be an ordinate to the tranſverſe (*fig.* 18) and MO perpendicular to the tangent at M, and S, F, the foci, then $CA^2 : CF^2 :: CP : CO$.

Cor. I. $CA^2 : CD^2 :: CP : PO$.

Cor. II. $2\,CA$: latus rectum $:: CP : PO$.

Cor. III. $CA : MF :: CF : OF$.

Prop. XII. MO, as before being perpendicular to the tangent in M, then $MO^2 = SM \times MF - SO \times OF$.

Cor. I. $MO = \frac{CD}{CA}\sqrt{SM \times MF}$; or $CA^2 : CD^2 :: SM \times MF : MO^2$.

Cor. II. $SM \times MF = MO^2 + BO \times OA - CD^2$.

Prop. XIII. If through any point M (*fig.* 19.) the line SG, equal to BA, be drawn from the focus F, and the line MD be drawn to the middle of FG, then MD will touch the curve in M.

Cor. I. The tangent at M biſects the external angle FMG made by two lines drawn from the focus.

Cor. II. The tangent at A and B are perpendicular to the tranſverſe axis AB; likewiſe a tangent at the end of the conjugate is perpendicular to the conjugate.

Prop. XIV. If PM (*fig.* 20.) be an ordinate, AD a line drawn from the ends of the tranſverſe and conjugate axes, and PQ parallel to AD then $PM^2 = CD^2 - CQ^2 = DQ \times QE$.

Prop. XV. If PM be an ordinate as before, and MH be drawn perpendicular to the curve at M, cutting the tranſverſe and conjugate axes at O and H, it will be as $OP : OC :: CD^2 : CF^3$, F being the focus.

Cor. I. $CD^2 : CF^2 :: MO : OH :: MP : CH :: PO : CO$.

Cor. II. If L be the latus rectum of AB, then as $L : AB - L :: MO : OH :: OP : OC :: MP : CH$.

Cor. III. $CA^2 : CD^2 :: CH + PM : PM :: CP : OP$.

Prop. XVI. If PM be an ordinate to the tranſverſe, MT a tangent at M, then CP, CA, and CT, are in continued proportion, C being the center.

Cor. I. If MO be perpendicular to MT, then OP, CD, and CT, are continually proportional.

Cor. II. $BP : PA :: BT : AT$, and conſequently BT is harmonically divided in the points P and A.

Prop. XVII. If MG be an ordinate to the conjugate, MV a tangent at M, C the center, then CG, CD, CV, are in continued proportion.

Cor. I. If MH be perpendicular to the tangent MV, then HG, CA, CV are continual proportionals.

Cor. II. $EG : GD :: EV : DV$; and EV is harmonically divided in the points G, D.

Prop. XVIII. If on the tranſverſe axis AB (*fig.* 21) as a diameter, a circle AKB be deſcribed, and the ordinate PM be drawn cutting the circle in N, then PN will always be to PM in the given ratio of the ſemitranſverſe CA to the ſemiconjugate CD.

Cor. If a circle be deſcribed on the conjugate axis DE, as a diameter, and an ordinate QR be drawn cutting the circle in I, then QI will always be to QR in the given ratio of the ſemiconjugate CD to the ſemitranſverſe CB.

Prop. XIX. (*fig.* 21.) If the line FD be drawn from the focus, perpendicular to any tangent MD, then the interſection D will be in the circumference of the circle ADB, deſcribed on the diameter BA, the tranſverſe axis.

Cor. I. If a circle be deſcribed on the tranſverſe AB, and a tangent be drawn at M cutting it in D, H, and the lines FD and SH be drawn from the foci; then FD, and SH, are perpendicular to the tangent HMD.

Cor. II. If FS, be the foci, C the center, MD a tangent at M, then if CD be drawn parallel to SM to cut the tangent in D, CD and CA will be equal to each other.

Cor. III. If a tangent HD interſects the circle AHB, in D and H, the perpendiculars to it, DF and HS will paſs through the foci F and S.

Cor. IV. If CI be drawn parallel to the tangent at M, then will $IM = CA$.

Prop. XX. The lines SH and FD being drawn perpendicular to the tangent MD as before, $SH \times FD$ will be equal to $BS \times SA$.

Cor. $SH \times FD =$ the ſquare of the ſemiconjugate.

Prop. XXI. The tangent being produced to T, and the reſt as before, $HM : MD :: HT : TD$.

Cor. $HM : MD :: TC + CS : TC - CF$.

Prop. XXII. The ſame things being ſuppoſed as before, $HM \times MD = SM \times MF =$ the ſquare of the ſemiconjugate.

Prop. XXIII. $SM : MF ::$ ſquare of the ſemiconjugate : FD^2; and $MF : MS ::$ ſquare of the ſemiconjugate : SH^2.

Prop. XXIV. (*fig.* 22) If MP be an ordinate to the tranſverſe HMT a tangent at M, C the center; AK, CG, BH, perpendicular to AB. Then it will be as $AK : PM :: CG : BH$.

Cor. $TA : TP :: TC : TB$.

Prop. XXV. The ſame things being ſuppoſed as before $AK \times BH = PM \times CG = CD^2$, or the ſquare of the ſemiconjugate.

Cor. I. $AK \times BH = PM \times CG = \frac{1}{4}BA \times$ latus rectum $= BS \times SA$.

Cor. II. Lines drawn from H and K to the focus, make a right angle HSK.

Cor. III. Hence a circle deſcribed on the diameter HK, will paſs through the foci, SF.

Prop. XXV. (*fig.* 21.) If S, F, be the foci, HMD a tangent at M, MO perpendicular to it, and OG perpendicular to SM, then MG is equal to half the latus rectum.

Cor. I. If $L =$ the latus rectum of the tranſverſe axis, then $AB - L : L :: SO \times OF : MO^2$.

Cor. II. If MH be perpendicular to the curve at M, cutting the two axes in O and H, then $SO \times OF = MO \times OH$.

Prop. XXVI. (*fig.* 23.) If two circles BDA, KLV, be deſcribed about the ſemitranſverſe and conjugate diameters; and CD be drawn, and form D, DP perpendicular to BA; and from L, LI perpendicular to DP, then the point I will be in the ellipſis.

Prop. XXVII. The ſum of the ſquares of any two diameters which are conjugate to each other is equal to the ſum of the ſquares of the tranſverſe and conjugate axes.

Prop. XXVIII. All circumſcribing parallelograms, whoſe ſides are parallel to two conjugate diameters, are equal to the rectangle of the two axes.

Prop. XXIX. (*fig.* 24.) If CK be the ſemiconjugate to MC, and LQ an ordinate thereto, then $CM^2 : CK^2 :: ML \times LV : LQ^2$.

Cor. I. MV : its latus rectum $:: ML \times LV : LQ^2$.

Cor. II. The rectangles of the ſegments of any diameter are as the ſquares of their ordinates.

Cor. III. The diameter biſects all its double ordinates, and the ordinates are equal at equal diſtances from the center.

Prop. XXX. (*fig.* 21.) If MT, a tangent in M, cut the diameter BA in T, and the ordinate MP be drawn, then CP, CA, and CT, are continually proportional.

Cor. I. $BP : PA :: TB : TA$; and therefore BT is harmonically divided in A and P.

Cor. II. $PC : PA :: PB : PT$.

Cor. III. $TA : TP :: TC : TP$.

Cor. IV. Two tangents drawn from equal ordinates on each ſide the curve meet in the diameter.

Prop. XXXI. (*fig.* 25.) If two lines TL, TM, touch the ellipſis in H and K, and HK be drawn, and alſo if there be drawn from T any line as TI cutting HK in D, and the curve in F and I, then $TF : TI :: DF : DI$.

Prop. XXXII. If TH and TK, be two tangents at H and K, and HK be drawn, and any line SR cut HK, and the curve in D, X and Y, then $DS^2 : DR^2 :: XS \times SY : YR \times RX$.

Prop. XXXIII. (*Fig.* 26.) If any line GP, be drawn through the focus F, then the rectangle $GF \times FP = \frac{1}{2}GP \times \frac{1}{2}$ latus rectum.

Prop. XXXIV. As the tranſverſe axis is to the conjugate, ſo is the area of a circle, whoſe diameter is tranſverſe to the area of the ellipſis.

Cor. I. The area of a circle deſcribed on the conjugate, is to the ellipſis, as the conjugate is to the tranſverſe.

Cor. II. The correſpondent ſegments of the circle and ellipſis, are in the ſame proportion as the wholes.

Cor. III. The ellipſis is a mean proportion between two circles, deſcribed on the tranſverſe and conjugate diameters.

Cor. IV. The ellipſis is equal to a circle, whoſe diameter is a mean proportion between the two axes.

Cor. V. An ellipſis is to the rectangle of the two axes, as any circle is to the ſquare of its diameter.

Cor. VI. The area of ellipſes, are to one another, as the rectangles of their tranſverſe and conjugate axes.

PROBLEMS RELATING TO THE ELLIPSIS.

Prob. I. To deſcribe an ellipſis by motion. This may be performed by Definition I.

Prob. II. (*fig.* 27.) To deſcribe an ellipſis, by finding ſeveral points in the curve. About the axes AB deſcribe the circle

AEB; divide CB, into any number of equal parts, CL, LL, LL, &c. and draw LF, LF, LF, &c. parallel to CE, draw DB and L*o*, L*o*, L*o*, &c. parallel thereto; or rather from L neareſt to C, draw L*o* parallel to DB, and divide CD into parts equal to C*o*; draw *or*, *or*, *or*, &c. parallel to AB, and each equal to its correſpondent LF; then *r*, *r*, *r*, &c. are in the curve of the ellipſis.

Prob. III. (*fig.* 28.) Any diameter AB, being given in an ellipſis to find its conjugate. Draw HI, parallel to AB. Biſect AB and HI, in C and G, and through C and G, draw the conjugate DE.

Prob. IV. (*fig.* 28.) Any diameter AB, being given to draw an ordinate to it, from a given point in the curve, as H. Through the centre C, draw HK; and let KL, be drawn parallel to AB; then join LH, and it will be the double ordinate required.

Prob. V. (*fig.* 29.) From any given point M, in an ellipſis to draw a tangent. From the given M, draw MC to the centre, and find its conjugate CB (by Prob. III.) then from M, draw MG, parallel to CR, for the tangent required.

Prob. VI. (*fig.* 30.) Given the focus F, and three points M, N, P, of an ellipſis, to deſcribe the ellipſis. Draw NMK through two of the points, and NPI alſo through two, and draw MF, NF, PF, to the focus. Then make $FN : FM :: NK : MK$. Alſo $FN : FP :: NI : PI$. Draw KI, and MH, perpendicular to it, and FT, perpendicular to it from the focus, and make $FA : AT :: FM : MH$. Then produce TF to B, ſo that BF may be to BT, in the ſame ratio. And AB will be the axis, and the middle point C, the centre. Alſo make $CS = CF$, and S will be the other focus, from whence the ellipſis may be deſcribed by Definition I.

SECT. III.

OF THE HYPERBOLA.

Definitions.

1. If the ends of two threads, SPQ, and FPQ, (Plate II. *fig.* 31.) be faſtened at the points S and F; and be made to paſs through a ſmall bead, or pin, P, and knotted together at Q, then by taking hold of Q, and drawing the threads tight, if the bead be moved along the threads, the point P will deſcribe the curve *mp*APM, named an hyperbola. 2. If the end of the long thread be fixed at F, and that of the ſhort one at S, and the curve NBR, be deſcribed after the ſame manner, ſuch curve is called the oppoſite hyperbola; and both thoſe curves, MA*m* and NBR are named oppoſite ſections, or oppoſite hyperbolas. 3. The two fixed points F, and S, are named the foci. 4. The line AB, which paſſes through the foci when continued, and which is contained between the two parts of the curve, is called the tranſverſe axis. 5. The middle point of AB, (that is C) is the centre of the hyperbola, or of the oppoſite ſections. 6. If VY be drawn through the centre C, perpendicular to AB, and with the radius CF, and centre A, an arc be deſcribed, cutting VY in V and Y, then VY is called the conjugate axis. 7. Any line TO (*fig.* 32.) drawn through the centre C, and terminated at the oppoſite ſections, is called a diameter, and the extremity T, (or O) is its vertex; and the line drawn through the centre, parallel to the tangent at the vertex, is called its conjugate diameter. 8. If any diameter OT (*fig.* 32.) is continued within the curve, the part within, TP, is named the abſciſſa. 9. Any line PM, drawn parallel to the tangent, at the vertex T, and terminated at the abſciſſa and curve, is called an ordinate to that diameter TO. If it go quite through the curve, it is called a double ordinate. 10. The line LI (*fig.* 31.) drawn through the focus F, perpendicular to the tranſverſe axis AB, and terminated at the curve, is named the parameter, or latus rectum. 11. If the ends of the two axes be joined by the lines BY and BV, and through the centre C, two lines CH, and CG, be drawn parallel to BY and BV; or if VY, be placed at A, perpendicular to BA, and the lines CH and CG be drawn from the centre C, through E and D, then thoſe lines CH and CG, are named the aſſymptotes of the hyperbolas, or of the oppoſite hyperbolas. 12. When the tranſverſe and conjugate axes are equal, the curve is called an equilateral hyperbolas, or right angled hyperbola. 13. A right line which touches the hyperbola in one point T, (*fig.* 32.) but does not cut it (as TH) is called a tangent to it, in that point (T). 14. If two oppoſite hyperbolas, KO and TW, be in like manner deſcribed to the tranſverſe VY ($= DE$), and conjugate AB; ſuch are conjugate hyperbolas, with regard to the former.

Prop. I. The difference of the lines SP and FP, (*fig.* 31.) drawn from the foci to any point P, of the curve, is equal to the tranſverſe axis AB. For by conſtruction, $PS - PF = AS - AF = AB + BS - AF = AB$, becauſe $BS = AF$.

Cor. The foci are equally diſtant from the centre.

Prop. II. The ſquare of the diſtance of the focus from the centre, is equal to the ſum of the ſquares of the ſemitranſverſe, and ſemiconjugate. For make AE (*fig.* 31.) equal and parallel to CY, then the radius $CE = CF$, and in the right angled triangle CAE, $CE^2 = CA^2 + AE^2$; that is $CF^2 = CA^2 + AE^2 = CA^2 + CY^2$.

Cor. $CF^2 - AE^2 = CA^2$; and $CF^2 - CA^2 = AE^2 = CY^2$.

Prop. III. The rectangle of the focal diſtances from either vertex, $=$ ſquare of the ſemiconjugate. For make $AE = CY$ (*fig.* 31.) by the property of the circle $FA \times AS = AE^2 = CY^2$.

Cor. The rectangle of the diſtances of either focus from the two vertices, is equal to the ſquare of the ſemiconjugate.

Prop. IV. As the tranſverſe axis is the conjugate, ſo is the conjugate to the latus rectum of the tranſverſe, viz. $AB : VY :: VY : LI$ (*fig.* 33.) For by Prop. I. $LL - LF = BA = 2CA$, and $SL = 2CA + LF$; alſo $SL^2 = 4CA^2 + 4CA \times LF + LF^2$; and in the right angled triangle, SLF, $SL^2 = SF^2 + LF^2$; and ſubtracting LF^2, from theſe two values of SL^2, we have $4CA^2 + 4CA \times LF = SF^2 = 4CF^2$; and $CF^2 = CA^2 + CA \times LF$. But by Prop. II. $CF^2 = CA^2 + CY^2 = CA^2 + CA \times LF$; therefore $CY^2 = CA \times LF$; and multiplying by 4, $VY^2 = BA \times LI$.

Cor. I. As the tranſverſe is to the ſemiconjugate, ſo is the ſemiconjugate to half the latus rectum.

Cor. II. As the ſemitranſverſe is to the diſtance of the focus from the centre, ſo is the ſame diſtance to the ſum of the tranſverſe and half the latus rectum.

Cor. III. The rectangle $BF \times TA = \frac{1}{2}$ tranſverſe $\times \frac{1}{2}$ latus rectum $= CA \times FL$.

N. B. The third proportional to any diameter and its conjugate, is called the latus rectum of that diameter, and therefore in any right angle hyperbola, every diameter is equal to its latus rectum.

Prop. V. From any point M, in the curve (*fig.* 34.) if the lines MF and MS, to the foci be drawn, and alſo the ordinate PM, perpendicular to the tranſverſe axis AB; then it will be as the ſemitranſverſe, CA, is to the diſtance of the focus from the centre CF, ſo is the diſtance of the ordinate from the center CP, to half the ſum of the lines MS and MF. For make $CD = AC$, then $SM = CA + DM$ and $FM = SM - 2CA = DM - CA$. Alſo in the right angled triangle, SMP, $SM^2 = CA^2 + 2CA \times DM + DM^2 = SP^2 + PM^2 = \overline{CF + CP}^2 + PM^2 = CF^2 + 2CF \times CP + CP^2 + PM^2$. And in the right angled triangle FMP, $FM^2 = DM^2 - 2DM \times CA + CA^2 = FP^2 + PM^2 = \overline{CP - CF}^2 + PM^2 = CP^2 - 2CF \times CP + CF^2 + PM^2$; and ſubtracting the latter equation from the former, $SM^2 - FM^2 = 4CA \times DM = 4CF \times CP$; and $CF \times CP = AC \times DM$. But ſince $SM = DM + CA$ and $FM = DM - CA$, therefore $SM + FM = 2DM$, and $DM =$ half the ſum of SM and FM; wherefore $CF \times CP = CA \times$ half the ſum of SM and FM.

Cor. I. If F and S are the foci, and MP be an ordinate, then is $CA : CF :: CP : SM - CA$, or $FM + CA$.

Cor. II. $SM^2 - FM^2 = 4CF \times CP$.

Cor. III. $CA \times \overline{SM + FM} = 2CF \times CP$.

Prop. VI. If MP be an ordinate on the tranſverſe axis (*fig.* 34.) it will be, as the ſquare of the tranſverſe (BA^2) : ſquare of the conjugate (NE^2) :: rectangle of the ſegments of the tranſverſe ($BA \times PA$) : ſquare of the ordinate (PM^2). Make $SD = CA$, then $DM = \frac{SM + FM}{2}$, and (by Propoſi. 5.) $CA : CF :: CP : DM$; and by compoſition $CA : CA + CF$, or $BF :: CP : CP + DM$; and alternately $CA : CP :: BF : CP + DM$; and again by compoſition $CA : CA + CP$ or $BP :: BF : BF + CP + DM$. But $BF = BC + CF = SD + CF$; and $BF + CP + DM = SD + CF + CP + DM = SM + SP$. Therefore $CA : BP :: BF : SM + SP$. Alſo ſince $CA : CF :: CP : DM$, (by Diviſion) $CA : CF - CA$ or $AF :: CP : DM - CP$, and alternately $CA : CP - CA$ or $AP :: AF : DM - CP - AF$; but $AF = CF - CA = SC - SD$; therefore $DM - CP - AF = DM - CP + SD - SC = SM - SP$, and conſequently, $CA : AP :: AF : SM - SP$, and CA being to $BP :: BF : SM + SP$; therefore (by Multiplication) $CA^2 : AP \times BP :: AF \times BF : SM^2 - SP^2$. Now make CN or CE perpendicular to AB and equal to half the conjugate; then by Prop. 3, $AF \times BF = CN^2$; and $SM^2 - SP^2 = PM^2$, whence $CA^2 : AP \times PB :: CN^2 : PM^2$ or $BA^2 : NE^2 :: BP \times PA : PM^2$.

Cor. I. The ſquare of the conjugate : ſquare of the ſemitranſverſe :: rectangle of the diſtances of the ordinate from the vertices : ſquare of the ordinate, viz. $CA^2 : CN^2 :: BP \times PA : PM^2$.

Cor. II. As the tranſverſe axis : latus rectum :: rectangle of the ordinates diſtances from the vertice : ſquare of the ordinate, viz. BA : latus rectum :: $BP \times PA : PM^2$.

Cor. III. The rectangle of the abſciſſas or diſtances of the ordinates from the vertices, of the figure, are as the ſquares of the ordinates.

Cor. IV. As the ſquare of the ſemi-tranſverſe : rectangle of the focal diſtances from the vertex :: rectangle of the ordinates diſtances from the vertices : ſquare of the ordinate.

Cor. V. The whole ordinates to the tranſverſe are biſected by the axis, and equal ordinates are equally diſtant from the centre.

If the reader has acquired perfect knowledge of the plain geometry, and qualified himſelf in the preceding ſections of conics, he will be enabled to demonſtrate for himſelf, the remaining propoſitions concerning the hyperbola, and as it is the propoſitions alone that can be of uſe in practical caſes; and were we to enlarge in demonſtrations, we muſt ſuppreſs many uſeful theorems, therefore in the remaining part of this ſection, the propoſitions, with their dependent corollaries will be given without the demonſtrations; at the ſame time we are perſuaded that there is not a work of this kind ſo ample on the ſubject.

Prop. VII. If MP be an ordinate to the tranſverſe axis (*fig.* 34.) C the center; F, S, the foci; and if CA be taken to $CF :: CP : CI$, then the rectangle $SM \times MF = CI^2 - CA^2$.

Cor. I. If $CA : CF :: CP : CI$, then $SM = BI$, and $FM = AL$.

Cor. II. The rectangle $SM \times MF = BI \times AI$.

Cor. III. $CA : CF :: CP : CA + FM :: CP : SM - CA$.

Prop. VIII. The ſame things be ſupported as in the laſt Prop. $CM^2 = CA^2 - CE^2 + SM \times MF$.

Cor. IV. If $CA : CF :: CP : CI$, then the rectangle $BPA =$ rectangle $SIF - MP^2$.

Prop. VIII. If two lines SM and FM (*fig.* 34.) be drawn from the foci to any point M in the curve, they will make equal angles with the curve in that point.

Cor. I. If KMO be drawn perpendicular to the tangent at M, then the angle $KMS = FMO$.

Cor. II. If MO be drawn perpendicular to the tangent at M, and SMD and FM be drawn from the foci, the angle $FMO = DMO$.

Prop. X. If MP (*fig.* 36.) be an ordinate to the tranſverſe axis, and MO perpendicular to the tangent at M, and S, F, the foci, then $CA^2 : CF^2 :: CP : CO$.

Prop. XI. The ſame things being ſuppoſed, $MO^2 = SO \times OF - SM \times MF$.

Cor. If MQ biſects the angle SMF, and MO be perpendicular to MQ, then $SQ : QF :: SO : OF$.

Prop. XII. If SM and MF be drawn from the foci to any point M in the curve (*fig.* 34), and SG be made equal to BA and FG be drawn, and if MD be drawn to the middle of FG, then MD will touch the curve in M.

Cor. I. The tangent at M biſects the angle SMF made by two lines drawn from M to the focus.

Cor. II. The tangents at the ends of the tranſverſe axis are perpendicular to that axis.

Prop. XIII. If MP be an ordinate (*fig.* 35.) DCE the conjugate axis, then if AD be drawn to the ends of the tranſverſe and conjugate axes, and PQ parallel to it, then $PM^2 = CQ^2 - CD^2 =$ rectangle $DQ \times QE$.

Prop. XIV. If MP be an ordinate (*fig.* 36.) F the focus and HMO be drawn perpendicular to the curve at M cutting the conjugate CD in H, and the tranſverſe in O, then will $OP : OC :: CD^2 : CF^2$.

Cor. I. $CD^2 : CF^3 :: MO : OH :: MP : CH :: PO : CO$.

Cor. II. If L be the latus rectum of AB, then $L : L + AB :: MO : OH :: OP : OC :: MP : CH$.

Cor. III. $CA^2 : CD^2 :: CH - PM : PM :: CP : PO :: HM : MO$.

Prop. XV. If PM be an ordinate to the tranſverſes (*fig.* 36) MQ a tangent at M, C a centre; then CQ, CA, and CP are in continued proportion.

Cor. I. $BQ : AQ :: BP : AP$.

Cor. II. If CE be the ſemi-conjugate, MO perpendicular to MQ, and the reſt as before, then CQ, CE, and PO are in geometrical progreſſion.

Cor. III. All hyperbolas deſcribed on the ſame tranſverſe axis, AB will have their tangents to interſect at the ſame point of the axis Q, when the abſciſſa AP is the ſame.

Cor. IV. All tangents to the curve AM interſect the axis CA, between the centre, C, and vertex, A.

Prop. XVI. All hyperbolas on the ſame tranſverſe axis, will have their ordinates ſtanding on the ſame abſciſſa in a given ratio to one another; that is, as their reſpective conjugates.

Prop. XVII. If MT be a tangent at M (*fig.* 37.) and the line FD be drawn perpendicular to it from either, the interſection D will be in the circumference of a circle ADB deſcribed on the tranſverſe axis BA as a diameter.

Cor. I. If a circle be deſcribed on the tranſverſe axis AB, and a tangent at M cuts it in the points D and H, and FD, SH, be drawn from the foci to D and H, then FD, SH, are perpendicular to the tangent HMD.

Cor. II. If F, S, be the foci, C the centre, MD a tangent at M, and if CD be drawn parallel to SM to cut the tangent in D, then $CD = CA$, half the tranſverſe.

Cor. III. If a tangent MH interſects the circle $DAHB$ deſcribed on the tranſverſe, in D and H, the perpendiculars DF and SH being drawn to it, will paſs through the foci, FS.

Cor. IV. If CI be drawn parallel to the tangent at M to interſect SM, then will $IM =$ ſemi-tranſverſe CA.

Prop. XVIII. If FS be the foci (*fig.* 37.) C the centre, MH a tangent at M; and if SH and FD be drawn perpendicular to the tangent MH, then $SH \times FD = BS \times SA =$ ſquare of the ſemi-conjugate axis.

Prop. XIX. (*fig.* 37.) If FD and SH be perpendiculars to the tangent MH drawn from the foci, then $HM : MD :: HT : TD$.

Cor. $HM : MD :: CF + CT : CF - CF :: TS : TF$.

Prop. XX. If MH be a tangent at M (*fig.* 38), SH and FD perpendiculars on it from the foci, and CE the ſemi-conjugate axis, then the rectangle $HM \times MD =$ rectangle $SM \times FM - CE^2$.

Prop. XXI. The ſame things being ſuppoſed, $SM : MF :: SH^2 : CE^2 :: CE^2 : FD^2$.

Prop. XXII. (*Fig.* 39). If MP be an ordinate to the tranſverſe axis, MH a tangent at M, C the centre; AK, CG and BN perpendicular to AB, then $AK : PM :: CG : BN$.

Cor. Hence $TA : TP :: TC : TB$.

Prop. XXIII. If CE be the ſemi-conjugate and the reſt as before, then $AK \times BN = PM \times CG = CE^2 = BS \times SA = \frac{1}{4} BA \times$ latus rectum.

Cor. I. $FD \times SH = AK \times BN = CE^2$, &c.

Cor. II. The lines NS, KS, drawn to the focus, make a right angle NSK.

Cor. III. Hence a circle deſcribed on the diameter NK will paſs through the foci S and F.

Prop. XXIV. If S, F, be the foci (*fig.* 38.) MH a tangent at M, MO perpendicular to it, and OG perpendicular to SM, then MG is half the latus rectum.

Cor. If L be the latus rectum, then $AB + L : L ::$ rectangle $SO \times OF : MO^2$.

Prop. XXV. Any diameter as MN (*fig.* 40.) is biſected in the centre C.

Prop. XXVI. The difference of the ſquares of two conjugate diameters, is equal to the difference of the ſquares of the two axes.

Cor. In any equilateral hyperbola, every diameter is equal to its conjugate.

Prop. XXVII. All inſcribed parallelograms, whoſe ſides are parallel to two conjugate diameters, are equal to the rectangle of the two axes.

Prop. XXVIII. In an equilateral hyperbola, the ſquare of the ſemi-conjugate is equal to the rectangle of the diſtances of either vertex from the foci.

Prop. XXIX. In an equilateral hyperbola, the rectangle of the diſtances of the ordinate from the two vertices, is equal to the ſquare of the ordinate.

Prop. XXX. If CA (*fig.* 41.) be the ſemi-tranſverſe axis, CF and CH, the aſſymptotes, AD the ſemi-conjugate, PM an ordinate continued to F, then the rectangle $HM \times MF = AD^2$.

Cor. I. If the ordinates be continued to the aſſymptotes, the parts between the curve and aſſymptotes are equal, viz. $FM = GH$.

Cor. II. If more ordinates be drawn to cut the aſſymptotes, their rectangles are all equal.

Prop. XXXI. If from the point M of the curve, MK be drawn parallel to the tranſverſe axis AB, (*fig.* 41) cutting the aſſymptotes in I and K, then the rectangle $KMI = CA^2$.

Cor. I. The rectangle $IM \times MH = KM \times MF$.

Cor. II. If more lines be drawn parallel to CA all their rectangles are equal to one another.

Prop. XXXII. All inſcribed parallelograms between the aſſymptotes and the curve are equal.

Cor. I. The hyperbola continually approaches to the aſſymptote, but can never touch it, though continued ad infinitum.

Cor. II. If a line be drawn parallel to one aſſymptote, it will interſect the oppoſite hyperbolas in one point, and no more.

Prop. XXXIII. If two hyperbolas QE and FD, (*fig.* 42) have the ſame aſſymptotes CP, and CH, and if HDE be drawn parallel to the aſſymptote CP, then HD is to HE every where in the given ratio of CN to CP.

Cor. I. The area $FGHD$: area $QGHE$ :: ordinate GF : ordinate GQ, or as the inſcribed parallelogram CF to the inſcribed parallelogram CQ.

Cor. II. If $CG = GS = 1$, and $GF = .43429448$, then the area $FGHD$ is the common logarithm of the number GH.

PROBLEMS RELATING TO THE HYPERBOLA.

Prob. I. To deſcribe an hyperbola by continued motion. This may be done by Definitions 1 and 2.

Prob. II. To deſcribe an hyperbola by finding ſeveral points in the curve. Let BA (*fig* 43) be the axis, S, F, the foci. Take any point N beyond F, and with the extent AN, and one foot in F, deſcribe an arc M; then with the extent NB, and one foot in S, croſs the former arc at M. Thus find as many points as neceſſary and draw the hyperbola through them.

Prob. III. Any diameter AB (*fig.* 44) in an hyperbola, being given to find its conjugate. Draw any line KI parallel to AB and biſect it in L; through L and the centre C draw LC for the conjugate, which will be terminated by the conjugate hyperbolas.

Prob. IV. Any diameter AB (*fig* 45) being given to draw an ordinate to it. From a given point H in the curve, through the centre C draw the diameter HK; and from K draw KL parallel to AB; then from L draw LH for the double ordinate.

Prob. V. To draw a tangent to any point in the hyperbolas. This is done by drawing the ſemidiameter, and finding its conjugate (by Prob. 3) and then from the given point draw a line parallel to ſuch conjugate, and it will be the tangent required.

Prob. VI. The focus F (*fig.* 46) being given, as alſo three points in the curve to deſcribe the hyperbola through the two points NM, draw NMK, and alſo, through NP, draw NIP; likewiſe draw MF, NF, PF to the focus; and make $FN : FM :: NK : MK$; and $FN : FP :: NI : PI$. Then through K and I draw

KG, and FT and MH perpendicular to it. Take the points AB, ſo that FM : MH :: FA : AT :: BF : BT; ſo will BA be the axis, and C (the middle point) the centre; make BS = AF, and S will be the other focus; whence the hyperbola may be deſcribed (by Prob. 2.)

PART III.

CURVE LINES.

Having laid down the elements of thoſe curves named the conic ſections, it will be proper that nothing may be deficient in this ſyſtem, to mention the chief properties of ſuch other curves as have been inveſtigated by geometricians, and are in frequent uſe in matters of ſcience, namely the conchoid, ciſſoid, cycloid, quadratrix, logarithmic curve, ſpirals, &c. of which I ſhall treat ſeverally in theii due order.

SECT. I.

OF THE CONCHOID.

Definitions. 1. Suppoſe AQ (*fig.* 47) to be a ſtreight ruler in which the points A and B are fixed; then if this ruler be ſo moved that it always paſſes through the fixed point P, whilſt the point B ſlides along the right line CD, the curve NAFM deſcribed by the point A is called a *conchoid*, or the *conchoid of Nichomedes*. 2. If B be between A and P, the curve AFM is named the *ſuperior conchoid*. 3. If *a* is between PB, the curve *afg* is called the inferior conchoid. 4. If PT (*fig.* 48) is perpendicular to CD, and if B*a* in the inferior conchoid be greater than TP, the curve *a*P*f*ZP*g*, is called the nodated conchoid. 5. The fixed point P (*fig.* 47) is named the pole or centre of the conchoid. 6. The line CD (*fig.* 47) is called the directrix of the conchoid.

The chief properties of the conchoid are as under: — 1. All lines as AB (*fig.* 47) which paſs through the pole P, and which are comprehended between the curve and directrix, are equal. 2. The directrix of the conchoid (CD) is an aſſymptote to the curve, or approaches infinitely near, but never touches it. 3. If from any point A of the curve (*Fig.* 47) AH, and FTP be drawn perpendicular to the directrix HT, and AL parallel to it; and if the quadrant FGK be deſcribed cutting AL parallel in G; then PL × LG = TL × LA. Alſo AG = BT, and GL = HB; and this holds good likewiſe in the inferior conchoid. 4. In the ſuperior conchoid; if PTF and AH be perpendicular to the directrix HT, and AL parallel to it, then $\mathrm{TL}^2 : \mathrm{TF}^2 - \mathrm{AH}^2 :: \mathrm{PL}^2 : \mathrm{AL}^2$. Alſo putting FT = *a*PT = *b*, and axis TH = *x*, the ordinate HA = *y*, then the equation of the ſuperior conchoid is $\frac{\overline{b+y}\,\sqrt{aa-yy}}{y} = x = \mathrm{AL}$. 5. In the inferior conchoid, if P*f*T (*Fig.* 47) and *ab* be perpendicular to the directrix BT, and *al* parallel to it, then $\mathrm{T}l^2 : \mathrm{T}f^2 - a\mathrm{B}^2 :: \mathrm{P}l^2 : al^2$; alſo putting T*f* = *a*, TP = *b*, axis T*b* = *x* ordinate *ha* = *y*, the equation of the inferior conchoid will be $\frac{\overline{b-y}\,\sqrt{aa-yy}}{y} = x = al$. The ſame holds for the nodated conchoid, all the difference being, that there *a* is greater than *b*.

SECT. II.

OF THE CISSOID.

Definitions. 1, Let ABG (*Fig.* 49) be a circle, C the centre, QED a ſquare; and let P and F be two fixed points in the lines AP, and ED, ſo that GP = radius CG = EF = FD; and let CD, produced ad infinitum be perpendicular to CP; then if the ſquare QED be ſo moved that the ſide EQ may always paſs through the point P, whilſt the end D ſlides along the right line CD, the point F (in the middle of ED) will deſcribe the curve GFB, called the *ciſſord*, or the *ciſſord* of *Diocles*. 2. The circle ABG is called the generating circle. 3. The line CD is called the directrix. This curve has the following properties. 1. If AB and BG be quadrants, the ciſſoid paſſes through the point B. 2. If from any point F of the curve, FL be drawn parallel to the directrix CD, cutting the circle in M, then LM, LG, and LF are in geometrical progreſſion. Alſo if FOH be perpendicular to the directrix CD, then OD = LM, the ordinate of the circle, and putting GH = *x*, HF = *y*, and CG = *a*, the equation of the curve is $2axx - yxx = y^3$. Moreover the four lines AL, LM, LG, and LF, are in continued proportion, and if FL be produced to N, and NC be drawn, CD will be equal to FN. Likewiſe $\mathrm{FH} : \mathrm{AL} :: \mathrm{GH}^2 : \mathrm{FH}^2$. 3. If AE be perpendicular to AG, then AE is an aſſymptote to the curve. 4. Through any point X of the curve draw GY cutting the circle in M and the aſſymptote in Y, then GX = MY. 5. If GS (*Fig.* 50) be perpendicular to the diameter AG, and from any point F in the curve FN be drawn parallel to GS cutting the circle in N, and ASN be drawn, then NF = GS; the line IZ = LF; and NF being made perpendicular to AG, and GF being drawn, NF, GF, and LF are in continued proportion, as are alſo GS, GF, and LF. 6. Through any point F, NF being as before perpendicular to AG, and GS parallel to it, and ANS being drawn, then GN : GF :: GL : LF :: AG : GS. — Alſo AN : NG :: NG : GF :: GL : LF. 7. If the ſame things being ſuppoſed, $\mathrm{GA} : \mathrm{GL} :: \mathrm{GS}^2 : \mathrm{GF}^2$. 8. All ciſſoids are ſimilar figures; for the abſciſſas and ordinates of ſeveral ciſſoids will be in the ſame ratio when either of them is in a given ratio to the diameter of its generating circle.

SECT. III.

OF THE CYCLOID.

Definitions. 1. If a circle DEBL (*fig.* 51) be made to roll along the right line AF until the fixed point D, which at firſt touched the line at A, comes to touch it again at F, the point D will deſcribe the curve ADGF called a cycloid or trochoid. 2. The circle DEBL is called the generating circle. 3. The line DB perpendicular to the middle AF is the axis of the cycloid.

The cycloid has the following properties: — 1. The baſe of the cycloid AF (*fig.* 51) is equal to the circumference DEBL of the generating circle. 2. If PM be drawn parallel to the baſe BF, it will be equal to the arc DP. Alſo the ordinate of the cycloid is equal to the ſum of its arc and its ſine, viz. AM = DP + AP. 3. If AM be an ordinate cutting the circle in P; MT a tangent at M, then MT is parallel to the chord PD. Alſo if ME be parallel to PB then ME is perpendicular to the curve in M; likewiſe AP : AD :: AM : AT. 4. If the ordinate APM be drawn, then the arc of the cycloid DM is double the correſpondent chord DP, in the generating circle. Hence the length of the ſemicycloid DMF is double the diameter AB; and the length of the whole cycloidal curve is four times the diameter of the generating circle. Alſo DA, the arc DM, and 4 AB, are in continued proportion; and DA, arc DM, and 2DF, are in continued proportion. 5. If AM be an ordinate, and DA the abſciſſa, then $\mathrm{DB} : \mathrm{DA} :: \mathrm{DF}^2 : \mathrm{DM}^2$. And the abſciſſa DA is directly as the ſquare of the arc DM. 6. If MS be perpendicular to the baſe BF, then $\mathrm{DB} \times \mathrm{MS} = \mathrm{DB} \times \mathrm{MF} - \frac{1}{4}\mathrm{MF}^2$. 7. If MS be perpendicular to the baſe as before, and MA parallel to it, then SF = arc BP — ſine AP. 8. If APM be an ordinate, DN parallel to it, and NM parallel to AB, then the external cycloidal ſpace DNM is equal to the circular ſegment DAP. Alſo the area of internal cycloidal ſpace is equal to the rectangle DA × AM — the circular area AGD; and the area of the whole cycloidal ſpace DMFB is equal to thrice the area of the ſemicircle ADB = alſo to $\frac{3}{4}$ of the circumſcribing parallelogram; likewiſe the whole cycloidal ſpace without the circle DPBFM is double the ſemicircle DPB.

SECT. IV.

OF THE QUADRATRIX.

Definitions. 1. If ACBL (*Fig.* 52.) be the quadrant of a circle, and ſuppoſe the radius CL to move uniformly round the center C from A to B, and at the ſame time the line FG to move uniformly along AC, from A to C, and in a parallel poſition to CB, ſo that both motions may begin and end together. Then the point of interſection N, of the lines CL and FG, during the motion, will deſcribe the curve AND, named the *quadratrix*, or the *quadratrix* of *Dinoſtratus*. 2. The circle ALB is called the generating circle. 3. The radius AC is called the axis, and CD the baſe.

The following are the properties of this curve: 1. If through any point N of the curve the radius CNL be drawn, and NF be parallel to CB, then AF : AC :: angle ACN : angle ACD; and as AF : FC :: angle ACN : angle NCD. Alſo the abſciſſas AF are as the angles at the center ACN. 2. The baſe is a third proportional to the quadrant and the axis, viz. ALGB : AC :: AC : CD. 3. If with the radius equal to the baſe CD, the quadrantal arc DPH be deſcribed, the ſame will be equal to the axis AC. 4. If through any point N of the curve, the radius CL be drawn and FN be parallel to the baſe, then CD : CA :: AF : arc AL. 5. Upon the baſe CD, if the quadrant DPH be deſcribed as before, and if through any point N of the curve NF be drawn perpendicular to AC, and CN, be drawn cutting the inſcribed quadrant in P, then AF will be equal to the arc HP; and FC = arc PD. 6. If the radius CA (*Fig.* 53) be continued to Q, ſo that AQ = AC, and the ſemicircle BAK be deſcribed; and if it be made AQ : AF :: AK : AL, and CL be drawn, and FN be parallel to CK, cutting CL in N, then will N be in the curve of the quadratrix continued without the circle, where the quadratrix DAN may be continued ad infinitum, by finding a ſufficient number of points N, *n*, &c.

N. B. The line QX, erected perpendicular to the line QAC, is an aſſymptote to the curve.

SECT. V.

OF THE LOGARITHMIC CURVE.

Definitions. 1. If in the line AE (*fig.* 54.) the parts AB, AC, AD, AE, &c. be taken in arithmetic progreſſion from the fixed point A, and at the points A, B, C, D, E, &c. the ordinates AF, BG, CH, DI, and EK, &c. be drawn parallel to one another, and in geometrical progreſſion; and if theſe ordinates are ſuppoſed infinite in number, or infinitely near to each other, then the curve line FGHIK, deſcribed through the extremities of all the ordinates is called the logarithmic curve. 2. The line AE is named the axis of the curve. The chief properties of this curve are the following: 1. The axis AE is an aſſymptote to the curve. 2. If TI is a tangent to the curve at I and DI an ordinate, then the ſubtangent TD is every where the ſame, in whatever place the point I be taken. 3. The ſpace (BDIG) comprehended between any two ordinates (BG and DI) is equal to the rectangle of the ſubtangent, and the difference of the ordinate, viz. $=$ TD $\times$ SI. Alſo the area of the whole curve infinitely produced towards A is equal to the rectangle of the ſubtangent and ordinate, viz $=$ ID$\times$TD, likewiſe the ſpace between any two ordinates is to the ſpace between any other two, as the difference of the firſt two, to the difference of the laſt two. 4. The ſolid made by the infinitely long ſpace FKEA revolving about the axis AE is equal to half a cylinder of the ſame baſe, and height equal to the ſubtangent, viz. $= \frac{1}{2}$TD $\times$ circle DI. Therefore the ſaid infinitely long ſolid is to a cone of the ſame baſe, and whoſe height is equal to the ſubtangent in the proportion of 3 to 2. 5. If AF $= 1$, BG $= a$AE $= x \times$ AB, EK $= y$, then the equation of the curve is $y = a^x$. 6. If the ordinates AF, BG, CH, &c. repreſent numbers in geometrical progreſſion, and be placed at equal diſtances, the abſciſſas AB, AC, AD, &c. being in arithmetical progreſſion, will repreſent the logarithms of theſe numbers. Hence logarithms may be of as many different ſorts as we pleaſe, but as a multiplicity of ways would be uſeleſs, mathematicians confine themſelves to two ſorts only, 1. When AF, BG, CH, DI, &c. are 1, 10, 100, 1000, &c. and AD, AC, AD, AE, &c. are 1, 2, 3, 4, &c. which are named the common or Briggs's Logarithms, the ſubtangent being .43429448. 2. In Napier's or the Hyperbolic Logarithm, the ſubtangent is 1. 7. If DI, EK, be two ordinates, then DE $=$ Log. $\frac{\text{EK}}{\text{DI}}$.

SECT. VI.

OF THE SPIRAL OF ARCHIMEDES.

Definitions. 1. If the radius CA (*fig.* 55.) be moved uniformly round the centre C, deſcribing the circle ABDA, and at the ſame time a point is ſuppoſed to move uniformly along that radius, from C to A, ſo that both motions begin and end together, the curve CFGA, deſcribed by that point, is called the *ſpiral of Archimedes*; and if the radius produced, moved round a ſecond time, while the deſcribing point continues its motion, the curve deſcribed is the *ſecond ſpiral*, and ſo on. 2. The circle ABDA, is called the generating circle; the properties of this ſpiral, are, 1. That if F be any point in the curve, then will CF : radius CA : : arc AB : circumference ABDA. Therefore, if the angles about C, be taken in arithmetical progreſſion, the diſtances of the moving point from C, will alſo be in arithmetical progreſſion; alſo the angles about the centre, are as the diſtances of the moving point from the centre. Likewiſe, if the radius CA $= r$; the circumference ABDA $= c$; any arc ABD $= z$, and its ordinate CP $= y$ then the equation of the curve, is $y = \frac{rz}{c}$. 2. If to any point P of the cu:ve, CPD be drawn from the centre, and CT perpendicular to it; and if there be made the radius CA : arc ABD : : CP : CT, and PT be drawn, then will it be a tangent to or touch the curve in P. 3. If F be any point in the curve, and if with radius CF, the arc FS be deſcribed, then AC^2 : CF^2 : : circumference ABD : arc FG. 4. The ſpiral ſpace CFPC is equal $\frac{1}{3}$ the ſector CPQL, whoſe radius is CP, and arc PQL. Alſo the whoſe ſpiral ſpace CFPA $= \frac{1}{3}$ of the generating circle ABDA. 5. If the firſt circle be A, the firſt, ſecond, third, or fourth, &c. ſpiral ſpace will be $\frac{1}{3}$ A, $\frac{7}{3}$ A, $\frac{19}{3}$ A, A, &c. Alſo if *a*, *b*, *c*, *d*, &c. be the firſt, ſecond, third, fourth, &c. ſpiral ſpace, and AB, CD, &c. the correſpondent circles, then will *a*, *b*, *c*, *d*, &c. be reſpectively equal to $\frac{1}{3}$ A, $\frac{7}{12}$ B, $\frac{19}{27}$ C, $\frac{37}{48}$ D, &c. And the area of the n^{th} ſphiral will be $\frac{1}{3}$ A $\times 3n \times \overline{n-1}+1$. Likewiſe the ſpiral ſpaces contained between every two ſucceeding circles are 2A, 4A, 6A, 8A, &c.

SECT. VII.

LOGARITHMIC SPIRAL.

Definitions. 1. If the curve FGDA (*fig.* 56.) be drawn about the centre C, ſo that it may every where cut the radii CF, CD, CG, CA, &c. in one and the ſame angle, that curve is called the *logarithmic or proportional ſpiral*. 2. The lines CF, CD, CG, &c. are called ordinates; to this ſpiral belongs the following properties. 1. If any number of ordinates CF, CK, CD, CA, &c. be drawn (*fig.* 57.) making equal angles at the centre C, then thoſe ordinates are in continued proportion. 2. If the angles at the centre, are in arithmetic progreſſion, the ordinates will be in geometrical progreſſion. 3. The ſpiral makes an infinite number of revolutions, before it comes to the centre C. 4. Let any radius CA, cut the ſpiral in its ſeveral revolutions, then the diſtances of the ſeveral points of interſection from the centre, will be in geometric progreſſion, and that in the ratio of CA to CB. 5. If CD, CE, CF, CA, &c. (*fig.* 58.) be in geometric progreſſion, and CD $= 1$, then will the angles DCE, DCF, DCA, &c. be the logarithms of CE, CF, CA, &c.

6. If CF is an ordinate and CT perpendicular to it, and if the angle CFT be made equal to the angle of the ſpiral, then FT is a tangent at F. Hence TF is to CF every where in the ſame given ratio. 7. If FT be a tangent at F, and CT perpendicular to the ordinate CF, then will the length of the whole ſpiral FEDC be equal to the tangent TF. 8. If FS be a tangent at F, and CS perpendicular to FS; CA, CF ordinates, then FS : CF : : AC—FC : AF, the length of the ſpiral contained between the ordinates. 9. If CF be an ordinate and FT a tangent, CT perpendicular to CF, then the area of the ſpiral ſpace FDC deſcribed by a radius making an infinite number of revolutions is equal to half the triangle TCF. But the area here mentioned is that made by an infinite number of revolutions of the radius, where every ſucceeding revolution covers a part of the former, and ſo the ſame parts of the area are deſcribed over and over. The real area of the ſpiral ſpace FEDGF, comprehended between the part of the ordinate GF, and the curve FEDG is equal $\frac{\text{TC}}{4\text{FC}} \times \overline{\text{FC}^2 - \text{GC}^2}$. 10. In the ſpiral CAB (*fig.* 59.) if the ordinate CA $= 1$, and the circle ADE be deſcribed with the radius CA, and any other ordinate CB be drawn, then the arc A$=$log. CB. Alſo from the point A where it cuts the circle if the tangent AT be drawn, and CT be perpendicular to CA; and if the ſubtangent C be .43429448, then AD is Brig's logarithm of the number denoted by CB. If the ſubtangent CF be 1, then AD is Napier's Logarithm of CB.

SECT. VIII.

OF THE HYPERBOLIC SPIRAL.

Definitions. Draw any line CG (*fig.* 60,) and C as a centre, deſcribe as many arcs of circles as you pleaſe from CG, to wit, VE, GF, *gf*, &c. all equal to one another, then the curve paſſing through all the points, which terminate theſe arcs, as FE*fd*C is called the hyperbolic or reciprocal ſpiral. 2. Any right line drawn from the centre to the curve, as CF is called an ordinate. 3. The line CG is named the axis. This ſpiral contains theſe properties, viz. 1. If CA be perpendicular to the axis GC, and equal to any of the arcs VE, GF, &c. and if AB be parallel to CG, then AB is an aſſymptote to the curve. Alſo the diſtance of the aſſymptote from the axis is equal to any arc GF between the axis and the curve. 2. Through any point F of the curve, draw the arc GF and the ordinate CF, and draw any other ordinate as CE, cutting the arc GF in L, then will CF$\times$GF$=$CE$\times$arc GL. 3. If HT be a tangent at any point H, (*fig.* 61) and CT be drawn perpendicular to CH, then the ſubtangent CT $=$ arc IH, $=$ alſo CA, the diſtance of the aſſymptote from the curve. The angle CHT continually encreaſes in approaching the center; and conſequently the curve makes an infinite number of revolutions about the center. If CF and CE (*fig.* 60) be any two ordinates, theſe ordinates are reciprocally as the angles they make with the axis CG, viz. CF : CE : : $\angle$GCE : $\angle$GCF. 5. The length of the ſpiral between any two ordinates is equal to the length of the logarithmic curve, between two ordinates of equal lengths with the former, when the ſubtangents of both curves are the ſame.

6. The ſpiral ſpace F*f*RF (*fig.* 62.) continued between the curve and part of the ordinate RF $= \frac{1}{2}$ CT$\times$RF. Alſo any part of a ſpiral ſpace contained between two ordinates CF, C*f* $= \frac{1}{2}$ CF $\times$CF — C*f*, FT being a tangent to the curve at the point F. 7. The ſpiral ſpace contained between any two ordinates is equal to half the ſpace in the logarithmic curve contained betwyeen two ordinates equal to the former, when the ſubtangents of both curves are the ſame.

SECT. IX.

OF THE CATENARY.

Definition. If a ſlack heavy line or rope, equally flexable, be ſuſpended at the ends on two fixed points, then the curve which the line by its own gravity would form itſelf into, is named the catenary; or, if upon the perpendicular AB (*fig.* 63.) as an axis, and the vertex A, an equilateral hyperbola AH be deſcribed whoſe ſemi-axis AC $= a$; and alſo upon the ſame axis and vertex a parabola AP whoſe parameter is quadruple, the axis of the hyperbola and the ordinate of the hyperbola HB be always produced till HF be equal to the curve AP, then making BD and BF equal, the curve FAD, in which the points FD are poſited, is the catenage. The following are ſome of the properties of this curve. 1. The ordinate BF $=$ parabolic curve AP — correſpondent ordinate BH. 2. The curve of the catenary AF is equal to BH, the correſpondent ordinate of the conterminal equilateral hyperbola. 3. All catenaries are ſimilar to one another. 4. Two right lines ſimilarly inclined to the horizon and carried through the vertices of catenarian curves will cut off ſimilar figures. 5. If the catenary QAD be ſuſpended on the points Q and D, which are *unequally* high, the part FAD of the curve remains the ſame as if it were ſuſpended by the points F and D, which are *equally high*. 6. If the force of the cartenary drawing in the direction dD, be divided into the force $d\delta$ acting with an horizontal direction, and the force δD with a perpendicular direction, then the force, in the end of the catenary of approaching directly to the axis, is to the force of deſcending perpendicularly in the ſame, (viz. that part of the ſuſtaining force that acts in the direction BD, is to that part which acts in the direction D) as the ſemi-axis of the conterminal hyperbola AH, to DA (the length of the catenary) to the vertex, whence the catenary being given, this ratio is alſo given and in the ſame catenary, ſuſpended with different degrees of laxity, that horizontal force is as the axis of the conterminal hyperbola.

7. If a tangent to the catenary in any point D, be produced to meet the axis in F (*fig.* 63.) then will D : BT : : ($d\delta$: δD : :) a : curve DA. 8. In the catenary the fluxion of the ordinate BF, is to the fluxion of the abſciſſa AB, as the conſtant force exerted perpendicularly on the correſpondent parts of the catenary to the curve AF, or, putting AB $= x$, and the conſtant force $= a$, then $\frac{a\dot{x}}{\sqrt{2ax+xx}} : \dot{x} :: a$: curve AF, and therefore its length will be determined. Or, if AD (*fig.* 64.) be the catenarya, AB $=$ X, BD $= y$, curve line AD $= v$, and a, as before, then the equation of the curve is $vv = 2ay + yy$; and the area $= \overline{v-x} \times a$.

It muſt however, be obſerved that the catenary, though here introduced, is not a geometrical curve, and that the above expreſſion exhibiting the area thereof, though true upon mechanical and fluxional principles,' can be of little uſe in practical matters, as the quantity a, though conſtant, is not given. Wherefore the areas of curves of this kind are beſt determined by the method of equidiſtant ordinates; which method will be given in the Syſtem of Menſuration and Gauging.

SECT. X.

OF THE EPICYCLOID.

DEFINITIONS.

The epicycloid is a curve generated by the revolution of the periphery of a circle along the convex, or concave part of another circle, which part of this other circle is named the baſe of the epicycloid, as in (*fig.* 65.) DB is the baſe of the epicycloid, V, its vertex, VB its axis, DPV half of the exterior epicycloid, made by the revolution of the ſemi-circle VLB (which is called the generant) along the convex ſide of the baſe DB; in like manner, as DPu in the anterior epicycloid is formed by the generant's revolving along the concave ſide of the baſes.

The quadrature of a portion of the epicycloid is given by Mr. Caſwell in the Philoſophical Tranſactions, N° 217, as follows: Biſect the arc of the ſemicircle VB in L, and on the center C through L, draw a circle cutting the epicycloid in P, then the ſquare of the ſemidiameter of the generant circle will be to the curve linear triangle VLP, as CB, the ſemi-diameter of the baſe to CE, which CE in the exterior epicycloid is the ſum of the ſemidiameters of the baſe and generant, but in the interior epicycloid Dpu it is the difference of the ſaid diameters. Mr. Caſwell ſays he deduced his concluſion from the following propoſition, viz. the ſegments of the generant circle are to the correſpondent ſegments of the cycloid, as CB to 2CE+CB, and the whole epicycloid is to the whole generant in the ſame proportion.

It would be endleſs to enumerate the different ſpecies of curves, as they are infinitely various; but if the reader has qualified himſelf in plain geometry and the conic ſections, and made himſelf maſter of the analytic art, he will be enabled by a careful attention to the nature and geneſis of any curve, and a due application of fluxions, to inveſtigate its properties, length, quadrature, &c. let it be of what order or kind it may. I ſhall therefore conclude the Syſtem with a few uſeful remarks upon curve lines in general.

1. If the abſciſſa of a curve be repreſented by x, and the ordinate by y; and the nature of the curve be expreſſed by an equation, between x and y, then if any particular value be aſſigned to x, there will be as many values for y as is the index of its higheſt power in the equation, and no more.

2. In like manner for any particular value of y, there are as many values of x, as the higheſt power of it has dimenſions in the equation.

3. Among the ſeveral values of y for any determinate value of x, thoſe that are affirmative are drawn on the upper ſide of the abſciſſa to the curve, and thoſe that are negative, are drawn from the abſciſſa downwards to the curve; alſo among the values of x, for any particular value of y, if thoſe that are affirmative lie from the origin of the abſciſſa to the ordinates on the right, then thoſe that are negative will lie from the origin of abſciſſa to the ordinate on the left hand.

4. When ſuch a value of x is aſſigned that in the reſulting equation ſome of the roots are impoſſible, it denotes that ſuch ordinates as are repreſented by thoſe impoſſible roots do not reach the curve, and in that caſe there is in reality no ſuch ordinate. Therefore by aſſigning ſeveral values of x, you may determine as many values of y as you pleaſe, and by that means find as many points of the curve as are neceſſary, and a line being drawn through all theſe points will be the locus of that equation.

5. In aſſigning any particular value for x of one root, or value of y be 0, then the curve cuts the abſciſſa in that point; but if y be infinite, the ordinate to that point is an aſſymptote to the curve, which runs out ad infinitum.

6. If x be infinite, and ſome value of y is 0, it ſhews that x, or the abſciſſa, is an aſſymptote to ſome branch of the curve which runs on infinitely.

7. If a curve is defined by an equation ſhewing the relation of the abſciſſa (x) and ordinate (y) a right line may cut that curve in as many points as the higheſt power of x has dimenſions in that equation, and not in more points. Hence one root alone cannot vaniſh out of the equation, or one ordinate vaniſh out of the curve; but two muſt vaniſh together.

8. In a line of a third, fifth, &c. or of any order whoſe dimenſion is an odd number, the abſciſſa, or any right line not parallel to an aſſymptote, will cut the curve at leaſt in one point. Hence if a right line touch a curve line of the third order, it will neceſſarily cut the curve in ſome point. Alſo if the right line touch ſuch a curve in the point of contrary flexure, it will cut the curve in that point, and no where elſe. But if a right line cut a curve in a double point of the curve, this muſt be eſteemed as two points, and a line that touches one arch of the curve in that point, will alſo cut the other in the like point.

9. An aſſymptote may interſect the curve in ſo many points, abating two, as the equation of the curve has dimenſions, and in no more.

10. Lines of the third, fifth, ſeventh, &c. order, have at leaſt two infinite legs or branches running contrary ways.

11. In lines of the ſecond, fourth, ſixth, or any even number of dimenſions, the roots of the equation may be all impoſſible, and then the figure may return into itſelf, and be contained within certain bounds.

12. In any curve, if tangents be drawn to all points of the curve, and if they always cut the abſciſſa at a finite diſtance from the beginning of it, that curve has an aſſymptote, otherwiſe not.

13. A line of any order may have as many aſſymptotes as it has dimenſions, and not more.

14. Any geometrical curve, being continued, either returns into itſelf or goes on to an infinite diſtance; for ſuch curve may be conſidered as deſcribed by the motion of a point, and this being effected by ſome certain law, the motion muſt neceſſarily continue ad infinitum; and therefore the ſpace run through (to wit, the line itſelf,) muſt either return back or proceed on infinitely, by reaſon of the regular motion of the deſcribing point; and therefore, if any curve has two infinite branches, or legs, they join one another, either at a finite or at leaſt at an infinite diſtance.

15. The ſhadow of any given curve line, projected from a lucid point, upon an infinite plane, will be a curve of the ſame gender with the given one. Hence the ſhadow of a circle or conic ſection, will be a conic ſection. The ſhadows of lines of the third order, will be lines of the third order, and ſo on ad infinitum.

16. If any part of the curve be higher (or further from the plane) than the light is, that part of the curve can caſt no ſhadow upon the plane, and the ſhadow of the curve will run on infinitely towards that hand, and therefore whatever there is in that part of the curve above the light will be quite loſt in the ſhadow, and be no where found.

The firſt part of this Syſtem, which treats of Plain Geometry, I have ſelected principally from that excellent treatiſe written by the late Thomas Simpſon, F.R.S. Profeſſor of Mathematics at the Royal Academy at Woolwich, and member of the Royal Academy of Sciences at Stockholm; judging that a proper extract from a work of ſuch eſtabliſhed reputation, would be more acceptable to the reader than any thing I could offer of my own.

Mr. Simpſon ſays that his deſign in writing upon Geometry, was to open an eaſy way for young beginners to arrive at a proficiency in that uſeful Science, without being either obliged to go through a number of unneceſſary propoſitions, or having recourſe to the ungeometrical methods of demonſtration, that abound in moſt modern compoſitions; *that he has ſpared no pains to render the work uſeful, and he believes that the ſpirit and rigour of demonſtration, ſo eſſential to the ſubject, are alſo tolerably well preſerved, though he ſuggeſts that he has not been ſo intent to guard againſt the attack of critics, as to loſe ſight of his main deſign of furniſhing a plain and eaſy inſtitution for learners.*

For the ſecond and third parts of this Syſtem, which contain the Elements of the Conic Sections and Curve Lines, I am chiefly indebted to Mr. Emerſon's Treatiſe, a work not leſs valuable than the former: and as the Editor of this undertaking is anxious, in every department of the work, to present the public with nothing but what is truly good and valuable in itſelf, ſo I hope that this brief Syſtem will merit a place in the New Royal Encyclopædia.

BRITISH 18 MR 63 MUSEUM

St. **GEORGE**, a name whereby ſeveral orders, both military and religious, are denominated. It took its riſe from a Saint famous throughout all the Eaſt, called by the Greeks Μεγαλομαρτυρ, q. d. *great martyr.*

St. George is particularly uſed for an Engliſh order of knights, more commonly now called the *order of the Garter*, which ſee.

GEORGIC, ſomething that relates to the culture or tilling of the ground.

GERANIUM, *cranes bill*, in botany, a genus of the decandria order belonging to the monodelphia claſs of plants. It ſtands recommended as one of the greateſt vulneraries and abſtergents of the vegetable world, and is highly extolled for its power of ſtopping profluvia of the menſes, and hæmorrhages of all kinds. Experience confirms the truth of this, eſpecially among the poor people in the country; and it were to be wiſhed that the plant could be brought into more eſteem in the ſhops, where at preſent it is diſregarded.

GERMAN, in genealogy, denotes *entire* or *whole:* thus, a brother-german is one by the father's and mother's ſide; and couſins-german are the children of brothers or ſiſters.

GERMEN, the ſeed-bud; defined by Linnæus to be the baſe of the piſtillum, which contains the rudiments of the ſeed; and, in progreſs of vegetation, ſwells and becomes a ſeed-veſſel. In aſſimilating the vegetable and animal kingdoms, Linnæus denominates the ſeed-bud the *ovarium* or *uterus* of plants; and affirms its exiſtence to be chiefly at the time of the diſperſion of the male-duſt by the antheræ; as after its impregnation, it becomes a ſeed-veſſel.

GERMINATION, the act of germinating; that is, of a plant's ſprouting, or ſhooting in the ground. Some uſe the word in a more extenſive ſenſe, ſo as likewiſe to include the firſt ſhooting out of leaves, bloſſoms, branches, flowers, roots, and ſeeds.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the ſingular number, through all the caſes except the vocative; as nom. *amandum*, gen. *amandi*, dat. *amando*, accuſ. *amandum*, abl. *amando*. The word is formed of the Latin *gerundivus*, and that from the verb *gerere*, to bear. The *gerund* expreſſes not only the *time*, but alſo the *manner*, of an action; as, "he fell in running poſt." It differs from the participle, in that it expreſſes the *time*, which the participle does not; and from the tenſe properly ſo called, in that it expreſſes the *manner*, which the tenſe does not.

GESTATION, the time of a woman's going with child, or the interval between *Conception* and *Delivery*. See FOETUS and PREGNANCY.

GESTICULATION, the making of affected, indecent, or unſuitable geſtures, or even of proper ones in too great number. *Geſticulation* is a great fault in an orator.

GESTURE, a motion of the body, intended to ſignify ſome idea or paſſion of the mind. *Geſtures* are a kind of natural language, which ſupplies the uſe of ſpeech in thoſe naturally dumb. The mimes and pantomimes were very great proficients in the ſtyle of *geſture*. *Geſture* conſiſts principally in the action of the hands and face; and may be defined, a ſuitable conformity of the motions of the countenance, and ſeveral parts of the body, in ſpeaking of the ſubject matter of the diſcourſe. See Treatiſe on the Art of ORATORY.

GIALLOLINO, in natural hiſtory, a ſpecies of yellow ochre uſed in painting, and called in the colour-ſhops, Naples yellow. It is both uſed as an oil and water-colour, and likewiſe in enamelling, encauſtic painting, and the colouring of china-ware.

GIANT, a perſon of extraordinary bulk and ſtature. The romances of all ages have furniſhed us with ſo many extravagant accounts of giants of incredible bulk and ſtrength, that the exiſtence of ſuch people is now generally diſbelieved. It is commonly thought, that the ſtature of man hath been the ſame in all ages. In the Scripture we are told of giants, who were produced from the marriages of the ſons of God with the daughters of men. But of this paſſage no ſufficient explanation hath yet been found: nor can we be ſure that the word tranſlated *giants* does there imply any extraordinary ſtature; ſeeing in other places it is explained by *falling away*, *revolting*, or *tranſgreſſing*. In other places of Scripture, however, giants, with their dimenſions, are mentioned in ſuch a manner that we connot poſſibly doubt; as in the caſe of Og king of Baſhan, and Goliath. Profane hiſtorians have given ſeven feet of height to Hercules their firſt hero; and in our days we have ſeen men eight feet high. The giant who was ſhewn in Rouen, in 1735, meaſured eight feet ſome inches. The emperor Maximin was of that ſize; Skenkius and Platerus, phyſicians of the laſt century, ſaw ſeveral of that ſtature; and Goropius ſaw a girl who was ten feet high. The body of Oreſtes, according to the Greeks, was eleven feet and a half; the giant Galbara, brought from Arabia to Rome under Claudius Cæſar, was near ten feet; and the bones of Secondilla and Puſio, keepers of the gardens of Salluſt, were but ſix inches ſhorter. Funnam, a Scotſman, who lived in the time of Eugene II. king of Scotland, meaſured eleven feet and a half: and Jacob le Maire, in his voyage to the ſtreights of Magellan, reports, that, on the 17th of December 1615, they found at Port Deſire ſeveral graves covered with ſtones; and having the curioſity to remove the ſtones, they diſcovered human ſkeletons of ten and eleven feet long. The chevalier Scory, in his voyage to the Pike of Teneriffe, ſays, that they found in one of the ſepulchre caverns of that mountain the head of a Guanche which had 80 teeth, and that the body was not leſs than 15 feet long. The giant Ferragus, ſlain by Orlando nephew of Charlemagne, was 18 feet high. Rioland, a celebrated anatomiſt, who wrote in 1614, ſays, that ſome years before there was to be ſeen in the ſuburbs of St. Germain the tomb of the giant Iſoret, who was 20 feet high. In Rouen, in 1509, in digging in the ditches near the Dominicans, they found a ſtone-tomb containing a ſkeleton whoſe ſkull held a buſhel of corn, and whoſe ſhin-bone reached up to the girdle of the talleſt man there, being about four feet long, and conſequently the body muſt have been 17 or 18 feet high. Upon the tomb was a plate of copper, whereon was engraved, "In this tomb lies the noble and puiſſant lord, the chevalier Ricon de Vallemont, and his bones." Platerus, a famous phyſician, declares, that he ſaw at Lucerne the true human bones of a ſubject which muſt have been at leaſt 19 feet high.

"At Totu, in Bohemia, in 758, was found a ſkeleton, the head of which could ſcarce be encompaſſed by the arms of two men together, and whoſe legs, which they ſtill keep in the caſtle of that city, were 26 feet long. The ſkull of the giant found in Macedonia, September 1691, held 210 pounds of corn. The celebrated Sir Hans Sloane, who treated this matter very learnedly, does not doubt theſe facts; but thinks the bones were thoſe of elephants, whales, or other enormous animals. Elephants bones may be ſhewn for thoſe of giants; but they can never impoſe on connoiſſeurs. Whales, which, by their immenſe bulk, are more proper to be ſubſtituted for the largeſt giants, have neither arms nor legs; and the head of that animal hath not the leaſt reſemblance to that of man. If it be true, therefore, that a great number of the gigantic bones which we have mentioned have been ſeen by anatomiſts, and by them have been reputed real human bones; the exiſtence of giants is proved."

With regard to the credibility of all, or any of theſe accounts, it is difficult to determine any thing. If, in any caſtle of Bohemia, the bones of a man's leg 26 feet in length are preſerved, we have indeed a deciſive proof of the exiſtence of a giant, in compariſon of whom moſt others would be but pigmies. Nor indeed could theſe bones be ſuppoſed to belong to an elephant; for an elephant itſelf would be but a dwarf in compariſon to ſuch an enormous monſter. But if theſe bones were really kept in any part of Bohemia, it ſeems ſtrange that they have not been frequently viſited, and particular deſcriptions of them given by the learned who have travelled into that country. It is certain, however, that there have been nations of men conſiderably exceeding the common ſtature. Thus, all the Roman hiſtorians inform us, that the Gauls and Germans exceed the Italians in ſize, and it appears that the Italians in thoſe days were of much the ſame ſtature with the people of the preſent age. Among theſe northern nations, it is alſo probable, that there would be as great differences in ſtature, as there are among the preſent race of men. If that can be allowed, we may eaſily believe that ſome of theſe barbarians might be called *giants*, without any great impropriety. Of this ſuperiority of ſize, indeed, the hiſtorian Florus gives us a notable inſtance in Teutobochus, king of the Teutones; who being defeated and taken priſoner by Marius, was carried in triumph before him at Rome, when his head reached above the trophies that were carried in the ſame proceſſion. But whether theſe accounts are credited or not, we are very certain, that the ſtature of the human body is by no means abſolutely fixed. We are ourſelves a kind of giants in compariſon of the Laplander; nor are theſe the moſt diminutive people to be found upon the earth. The abbe la Chappe, in his journey into Siberia, in order to obſerve the laſt tranſit of Venus, paſſed through a village inhabited by people called *Wotiacks*, neither men nor women, of whom were above four feet high. The accounts of the Patagonians alſo, which cannot be entirely diſcredited, render it very probable, that ſome where in South America there is a race of people very conſiderably exceeding the common ſize of mankind, and conſequently that we cannot altogether diſcredit the relations of giants handed down to us by ancient authors; though what degree of credit we ought to give them, is not eaſy to be determined.

GIANTS *Cauſeway*, a name given by the common people of the county of Antrim, in Ireland, to a vaſt quantity of that kind of black marble, called *Baſaltes*, which ſtands in columns, and is natural to that marble, and runs out a great way into the ſea. For a particular deſcription, ſee CAUSEWAY.

GIBBOUS, in ſurgery, is uſed to denote a perſon bunched or hump-backed.

GIBBOSITY is a preternatural incurvation of the ſpina dorſi, either backward, or on one ſide. Infants are more ſubject to this diſorder than adults, and it oftner proceeds from external, than internal cauſes. A fall, blow, or the like violence frequently thus diſtorts the tender bones of infants. When it proceeds from an internal cauſe, it is generally from a relaxation of the ligaments that ſuſtain the ſpine, or a caries of its vertebræ; though the ſpine may be inflected forward, and the back thrown out, by a too ſtrong and repeated action of the abdominal muſcles; and this, if not timely redreſſed, uſually grows up and fixes as the bones harden, till in adults it is totally irretrievable: but when the diſorder is recent, and the perſon young, there are ſome hopes of a cure. The common method is by a machine of paſte-board, wood, or ſteel, which is made to preſs principally upon the *gibbous* part, and this by long wearing may ſet all right. The ſurgeons, however, have a different inſtrument which they call a croſs, much more efficacious though not quite ſo convenient in the wearing; by the uſe of this, the parts are always prevented from growing any worſe, and are often cured. During the application of theſe aſſiſtances, the parts ſhould be at times rubbed with hungary-water, ſpirit of lavender, and the like, and defended with a ſtrengthening plaſter, oxycroceum, opodeldoc, or the like. The part of the liver, out of which the vena cava ariſes, is alſo called the *gibbous* part.

GIDDINESS, a name for the diſtemper, called by phyſicians VERTIGO. *Giddineſs* in horſes; for the cauſes and methods of treatment, ſee Syſtem of FARRIERY; Part II. Claſs 8. Sect. 25.

GIFT, *donum*, in law, is a conveyance which paſſeth either lands or goods, and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken ſtrictly, it is applicable only to lands and tenements given in tail; but *gift* and *grant* are often confounded.

GILDING, the art of ſpreading or covering a thing over with gold, either in leaf or liquid. The art of gilding was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. Pliny aſſures us, that the firſt gilding ſeen at Rome, was after the deſtruction of Carthage, under the cenſorſhip of Lucius Mumminus, when they began to gild the ceilings of their temples and palaces; the Capitol being the firſt place on which this enrichment was beſtowed. But he adds, that luxury advanced on them ſo haſtily, that in a little time you might ſee all, even private or poor perſons, gild the very walls, vaults, &c. of their houſes.

The modern gilders alſo make uſe of gold-leaves of divers thickneſſes; but there are ſome ſo fine, that a thouſand do not weigh above four or five drachms. The thickeſt are uſed for gilding on iron, and other metals; and the thinneſt, on wood. But we have another advantage over the ancients, in the manner of uſing or applying the gold: the ſecret of painting in oil, diſcovered of late ages, furniſhes us with means of gilding works that ſhall endure all the injuries of time and weather, which to the ancients was impracticable. The luſtre and beauty of gold have occaſioned ſeveral enquiries and diſcoveries concerning the different methods of applying it to different ſubſtances. Hence the art of gilding is very extenſive, and contains many particular operations and various management. A colour of gold is given by painting and by varniſhes, without employing gold; but this is a falſe kind of gilding. Thus a very fine golden colour is given to braſs and to ſilver, by applying upon theſe metals a gold-coloured varniſh, which, being tranſparent, ſhews all the brilliancy of the metals beneath. Many ornaments of braſs are varniſhed in this manner, which is called *gold lacquering*, to diſtinguiſh them from thoſe which are really gilt. Silver-leaves thus varniſhed are put upon leather, which is then called *gilt leather*. See LACQUER.

Amongſt the falſe gilding may alſo be reckoned thoſe which are made with thin leaves of copper or braſs, called *Dutch-leaf*. In this manner are made all the kinds of what is called *gilt paper*. In the true gilding, gold is applied to the ſurface of bodies. The gold intended for this purpoſe ought in general to be beat into thin leaves, or otherwiſe divided into very fine parts. As metals cannot adhere well merely by contact to any but to other metallic ſubſtances, when gold is to be applied to the ſurface of ſome unmetallic body, that ſurface muſt be previouſly covered with ſome gluey and tenacious ſubſtance, by which the gold ſhall be made to adhere. Theſe ſubſtances are in general called *ſizes*. Some of theſe are made of vegetable and animal glues, and others of oily, gluey, and drying matters. Upon them the leaves of gold are applied, and preſſed down with a little cotton or a hare's foot; and when the whole is dry, the work is to be finiſhed and poliſhed with a hard inſtrument, called a *dogs-tooth*, to give luſtre.

When the work is required to be capable of reſiſting rain or moiſture, it ought to be previouſly covered with a compoſition of drying oil and yellow ochre ground together; otherwiſe a water-ſize may be uſed, which is prepared by boiling cuttings of parchment or white leather in water, and by mixing this with ſome chalk or whiting: ſeveral layers of this ſize muſt be laid upon the wood, and over theſe a layer of the ſame ſize mixed with yellow ochre. Laſtly, another mixture, called *gold ſize*, is to be applied above theſe; upon which the gold leaves are to be fixed. This gold ſize, the uſe of which is to make the gold-leaf capable of being burniſhed, is compoſed of tobacco-pipe clay, ground with ſome ruddle or black lead, and tempered with a little tallow or oil of olives. The edges of glaſſes may be gilt by applying, firſt, a very thin coat of varniſh, upon which the gold-leaf is to be fixed; and when the varniſh is hardened, may be burniſhed. This varniſh is prepared by boiling powdered amber with linſeed oil in a braſs veſſel to which a valve is fitted, and by diluting the above ſolution with four or five times its quantity of oil of turpentine; and that it may dry ſooner, it may be ground with ſome white lead.

The method of applying gold upon metals is entirely different. The ſurface of the metal to be gilt is firſt to be cleaned; and then leaves are to be applied to it, which, by means of rubbing with a poliſhed blood-ſtone, and a certain degree of heat, are made to adhere perfectly well. In this manner ſilver-leaf is fixed and burniſhed upon braſs in the making of what is called *French plate*, and ſometimes alſo gold-leaf is burniſhed upon copper and upon iron. Gold is applied to metals in ſeveral other manners. One of theſe is by previouſly forming the gold into a paſte or amalgam with mercury. In order to obtain a ſmall amalgam of gold and mercury, the gold is firſt to be reduced into thin plates or grains, which are heated red-hot, and thrown into mercury previouſly heated, till it begins to ſmoke. Upon ſtirring the mercury with an iron rod, the gold totally diſappears. The proportion of mercury to gold is generally as ſix or eight to one. With this amalgam the ſurface of the metal to be gilded is to be covered; than a ſufficient heat is to be applied to evaporate the mercury; and the gold is laſtly to be burniſhed with a blood-ſtone.

Some metals, particularly ſilver, may be gilt in the following manner. Let gold be reſolved into aqua-regia. In this ſolution pieces of linen are to be dipt, and burnt to black aſhes. Theſe aſhes being rubbed on the ſurface of the ſilver by means of a wet linen rag, apply the particles of gold which they contain, and which by this method adhere very well. The remaining part of the aſhes is to be waſhed off; and the ſurface of the ſilver, which in this ſtate does not ſeem to be gilt, is to be burniſhed with a blood-ſtone till it acquire a fine colour of gold. This method of gilding is very eaſy, and conſumes a very ſmall quantity of gold. Moſt gilt ornaments upon fans, ſnuff-boxes, and other toys of much ſhow and little value, are nothing but ſilver gilt in this manner.

Gold may alſo be appplied to glaſs, porcelain, and other vitrified matters. As the ſurface of theſe matters is very ſmooth, and conſequently is capable of a very perfect contact with gold leaves, theſe leaves adhere to them with ſome force, although they are not of metallic nature. This gilding is ſo much more perfect, as the gold is more exactly applied to the ſurface of the glaſs. The pieces are then to be expoſed to a certain degree of heat, and burniſhed ſlightly to give them luſtre. A more ſubſtantial gilding is fixed upon glaſs, enamel, and porcelain, by applying to theſe ſubſtances powder of gold mixed with a ſolution of gum arabic, or with ſome eſſential oil, and a ſmall quantity of borax; after which a ſufficient heat is to be applied to ſoften the glaſs and the gold, which is then to be burniſhed. With this mixture any figures may be drawn. The powders for this purpoſe may be made, 1. By grinding gold-leaf with honey, which is afterwards to be waſhed away with water. 2. By diſtilling to dryneſs a ſolution of gold in aqua-regia. 3. By evaporating the mercury from an amalgam of gold, taking care to ſtir well the maſs near the end of the proceſs. 4. By precipitating gold from its ſolution in aqua-regia by applying to it a ſolution of green vitriol in water, or ſome copper, and perhaps ſome other metallic ſubſtances.

GILL, a meaſure of capacity, containing a quarter of an Engliſh pint.

GILLS, or *Branchiæ*, in itchthyology. See the Syſtem.

GIN See GENEVA.

GINGER, in botany. See AMOMUM.

GINGIDIUM, in botany. See ARTEDIA.

GINGIVA, in anatomy, the *gum*; a hard ſort of fleſh, inveſting the alveoli, or ſockets, of the teeth. The *gingivæ* are formed of the union of two membranes; one of which is a production of the perioſteum, and the other of the external membrane of the mouth.

GINGLYMUS, Γιγυμος, in anatomy, one of the ſpecies of articulation. See Syſtem of ANATOMY, Part I. Sect. 12.

GIN-SENG, or NIN-SENG, panax, in botany; for the characters and qualities of this plant, ſee PANAX.

GIRDLE, *Cingulus*, or *Zona*, a belt or band of leather, or other matter tied about the reins, to keep that part more firm and tight. It was anciently the cuſtom for bankrupts, and other inſolvent debtors, to put off and ſurrender their *girdle* in open court. The reaſon hereof was, that our anceſtors uſed to carry all the neceſſary utenſils, as purſe, keys, &c. tied to the *girdle*; whence the *girdle* became a ſymbol of the eſtate.

GIRDLE, in architecture. See CINCTURE.

GIRRONNE, GIRONY, in heraldry, is when a ſhield or coat is divided into ſeveral girons, which are alternately colour and metal.

GIRT, in architecture, the ſame with fillet. See FILLET.

GIVEN, *datum*, a term very frequently uſed in mathematics, ſignifying a thing which is ſuppoſed to be known. Thus, if a magnitude be known, or we can find another equal to it, we ſay it is a *given* magnitude, or that ſuch a thing is *given* in magnitude.

GLACIS, in building, an eaſy inſenſible ſlope or declivity. The *glacis* of the cornich is an eaſy imperceptible ſlope in the cymatium of the cornich, to promote the deſcent and draining off of the rain-water.

GLACIS, in fortification, is particularly uſed for that of the counterſcarp, being a ſloping bank, which reaches from the parapet of the counterſcarp, or covert-way, to the level ſide of the field, at the diſtance of about twenty fathom. See Syſtem of FORTIFICATION.

GLADIATORS, in antiquity, perſons who were retained to fight ordinarily in the arena, for the entertainment of the people. The *gladiators* were uſually ſlaves, and fought out of neceſſity, though, ſometimes, freemen made profeſſion thereof, like our prize-fighters, for a livelihood. After a *ſlave* had ſerved on the arena three years, he was diſmiſſed. The Romans borrowed this cruel diverſion from the Aſiatics: ſome ſuppoſe that there was policy in this practice, the frequent combats of *gladiators* tending to accuſtom the people to deſpiſe danger and death. The origin of ſuch combats ſeems to be as follows: from the earlieſt times with which we have any acquaintance, in prophane hiſtory, it had been the cuſtom to ſacrifice captives, or priſoners of war, to the manes of the great men who had died in the engagement: thus Achilles, in the Iliad, lib. xxiii. ſacrifices twelve young Trojans to the manes of Patroclus; and in Virgil, lib. xi. ver. 81. Æneas ſends captives to Evander, to be ſacrificed to the funeral of his ſon Pallas. In courſe of time they came alſo to ſacrifice ſlaves at the funerals of all perſons of condition; this was even eſteemed a neceſſary part of the ceremony; but, as it would have appeared barbarous to have maſſacred them like beaſts, they were appointed to fight with each other, and endeavour to ſave their own lives by killing their adverſary. This ſeemed ſomewhat leſs inhuman, becauſe there was a poſſibility of avoiding death, by an exertion of ſkill and courage. This occaſioned a profeſſion of *gladiator* to become an art: hence aroſe maſter of arms, and men learned to fight and and exerciſe this art. Theſe maſters, whom the latins called *laniſtæ*, bought them ſlaves to be trained up to this cruel trade, whom they afterwards ſold to ſuch as had occaſion to preſent the people with ſo horrible a ſhew. They were at firſt performed near the ſepulchre of the deceaſed, or about the funeral pile; but were afterwards removed to the circus and amphitheatres, and became ordinary amuſements.

The firſt ſhew of gladiators, called *manus gladiatorum*, was exhibited at Rome, according to Valerius Maximus, by M. and D. Brutus, upon the death of their father, in the year of the city 490. On this occaſion there were probably only three pair of *gladiators*; in the year of Rome 537, the three ſons of M. Æmilius Lepidus the augur, who had been three times conſul, entertained the people with the cruel pleaſure of ſeeing twenty-two gladiators fight in the forum. In the year of Rome 547, the firſt Africanus diverted his army at New-Carthage with a ſhew of gladiators, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In proceſs of time, the Romans became ſo fond of theſe bloody entertainments, that not only the heir of any great and rich citizen lately deceaſed, but all the principal magiſtrates, preſented the people with ſhews of this nature, to procure their affection. The ædiles, pretors, conſuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with theſe fights: and the prieſts were ſometimes the exhibitors of the barbarous ſhews; for we meet with the *ludi pontificales* in Suetonius, Auguſt. cap. 44, and with the *ludi ſacerdotales*, in Pliny. Epiſt. lib. vii. As for the emperors, it was ſo much their intereſt to ingratiate themſelves with the populace, that they obliged them with combats of *gladiators* almoſt upon all occaſions; and as theſe increaſed, the number of combatants increaſed likewiſe. Accordingly, Julius Cæſar, in his ædileſhip, diverted the people with three hundred and twenty couple. Titus exhibited a ſhew of *gladiators*, wild beaſts, and repreſentations of ſea-fights, which laſted a hundred days; and Trajan continued a ſolemnity of this nature for a hundred and twenty-three days, during which time he brought out a thouſand pair of gladiators. Before this time, under the republic, the number of gladiators was ſo great, that when the conſpiracy of Catiline broke out, the ſenate ordered them to be diſperſed into the garriſon and ſecured, leſt they ſhould have joined the diſaffected party. Theſe ſpots were become ſo common, and their conſequences, in a variety of reſpects, ſo dangerous, that Cicero preferred a law, that no perſon ſhould exhibit a ſhew of *gladiators* within two years before he appeared candidate for any office. Julius Cæſar ordered, that only a certain number of men of this profeſſion ſhould be in Rome at a time. Auguſtus decreed, that only two ſhews of *gladiators* ſhould be preſented in a year, and never above ſixty couple of combatants in a ſhew. And Tiberius provided by an order of ſenate, that no perſon ſhould have the privilege of gratifying the people with ſuch a ſolemnity, unleſs he was worth four hundred thouſand ſeſterces. They were alſo conſiderably regulated by Nerva. The emperor Claudius reſtrained them to certain occaſions; but he ſoon afterwards annulled what he decreed, and private perſons began to exhibit them at pleaſure, as uſual; and ſome carried the brutal ſatisfaction ſo far, as to have them at their ordinary feaſts. And not ſlaves only, but other perſons would hire themſelves to this infamous office. The maſter of the *gladiators* made them all firſt ſwear, that they would fight to death; and if they failed, they were put to death, either by fire, or ſwords, clubs, whips, or the like. It was a crime for the wretches to complain when they were wounded, or aſk for death, or ſeek to avoid it, when overcome; but it was uſual for the emperor, or the people to grant them life, when they gave no ſigns of fear, but waited the fatal ſtroke with courage and intrepidity: Auguſtus even decreed, that it ſhould always be granted them. From ſlaves and freedmen, the inhuman ſport at length ſpread to people of rank and condition; ſo that Auguſtus was obliged to iſſue a public edict, that none of the ſenatorian order ſhould become *gladiators*; and ſoon after he laid the ſame reſtraint on the knights: nevertheleſs, Nero is related to have brought upwards of four hundred ſenators, and ſix hundred Roman knights upon the arena; though Lipſius takes both thoſe numbers to be falſified, and, not without reaſon, reduced them to forty ſenators, and ſixty knights: yet Domitian, that other monſter of cruelty, refined upon Nero, exhibiting combats of women in the night time.

Conſtantine the Great is ſaid to have firſt prohibited the combats of *gladiators* in the Eaſt; at leaſt, he forbad thoſe who were condemned to death for their crimes, to be employed; there being an order ſtill extant to the præfectus prætorii, rather to ſend them to work in the mines in lieu thereof: it is dated at Berytus, in Phœnicia, the firſt of October, 325. The emperor Honorius forbad them at Rome, on occaſion of the death of Telemachus, who coming out of the Eaſt into Rome, at the time of one of theſe ſpectacles, went down into the arena, and uſed all his endeavour to prevent the *gladiators* from continuing the ſport, upon which the ſpectators of that carnage, fired with anger, ſtoned him to death. It muſt be obſerved, however, that the practice was not entirely aboliſhed in the Weſt before Theodoric, king of the Oſtrogoths. Honorius, on the occaſion firſt mentioned, had prohibited them; but the prohibition does not ſeem to have been executed. Theodoric, in the year 500 aboliſhed them finally. Some time before the day of battle, the perſon who preſented the people with the ſhews, gave them notice thereof, by programmas, or bills, containing the names of the *gladiators*, and the marks whereby they were to be diſtinguiſhed; for each had his ſeveral badge, which was, moſt commonly, a peacock's feather, as appears, from the ſcholiaſt of Juvenal, on the 158th verſe of the third ſatire, and Turnebus Adverſ. lib. ii. cap. 8. They alſo gave notice what time the ſhews would laſt, and how many couples of *gladiators* there were; and it even appears, from the 52d verſe of the ſeventh Satire of the ſecond book of Horace, that they ſometimes made repreſentations of theſe things in painting, as is practiſed among us by thoſe who have any thing to ſhew at fairs. The day being come, they began the entertainments by bringing two kinds of weapons; the firſt were ſtaves, or wooden files, called *rudes*; and the ſecond were effective weapons, as ſwords, poniards, &c.

The firſt were called *arma luſoria*, or, *exercitoria*; the ſecond *decretoria*, as being given by decree or ſentence of the prætor, or of him at whoſe expence the ſpectacle was exhibited. They began to fence or ſkirmiſh with the firſt, which was to be the prelude to the battle; and from theſe, when well warmed, they advanced to the ſecond, at the ſound of the trumpets, with which they fought naked. Then they were ſaid *vertere arma*; the terms of ſtriking were *petere & repetere*; of avoiding a blow, *exire*; and when one of the combatants received a remarkable wound, his adverſary or the people cried out, *habet*, or *hoc habet*. The firſt part of the engagement was called, *ventilare, præludere:* and the ſecond, *dimicare ad certum*, or *verſis armis pugnare*: and ſome authors think, with much probability, that it is to theſe two kinds of combat that St. Paul alludes, in the paſſage 1 Cor. ix. 26, 27. "I fight, not as one that beateth the air; but I keep my body, and bring it into ſubjection." If the vanquiſhed ſurrendered his arms, it was not in the victor's power to grant him life; it was the people, during the time of the republic, and the prince or people, during the time of the empire, that were alone impowered to grant the boon. The *gladiators* challenged or defied each other, by ſhewing the little finger; and by extending this or ſome other, during the combat, they owned themſelves vanquiſhed, and begged mercy from the people.

Dying **GLADIATOR**, is a moſt valuable ancient ſculpture, which is now preſerved in the palace of Chighi. This man, when he had received the mortal ſtroke, is particularly careful, *ut procumbat honeſte*, that he might fall honourably; he is ſeated in a reclining poſture on the ground, and has juſt ſtrength ſufficient to ſupport himſelf on his right arm; and in his expiring moments it is plainly ſeen that he does not abandon himſelf to grief and dejection, but is ſolicitous, to maintain that firmneſs of aſpect, which the *gladiators* valued themſelves on preſerving in this ſeaſon of diſtreſs, and that attitude which they had learnt of the maſters of defence. He fears not death, nor ſeems to betray any tokens of fear by his countenance, nor to ſhed one tear: *quis mediocris* gladiator *ingemuit, quis vultum mutavit unquam, quis non modo ſtetit, verum etiam decubuit turpiter*, ſays Cicero, in that part of his Tuſculan, where he is deſcribing the aſtoniſhing firmneſs of theſe perſons. We ſee, in this inſtance, notwithſtanding his remaining ſtrength, that he has but a moment to live, and we view him with attention, that we may ſee him expire and fall: thus the ancients knew how to animate marble, and to give it almoſt every expreſſion of life. Encyclopedie Françoiſe.

GLAIR *of Eggs*, is the ſame as the white of eggs, and is uſed as a varniſh for preſerving paintings. For this purpoſe it is beat to an unctuous conſiſtence, and commonly mixed with a little brandy or ſpirit of wine, to make it work more freely, and with a lump of ſugar to give it body and prevent its cracking; and then ſpread over the picture or painting with a bruſh.

GLAMA, in zoology, for a particular deſcription of which, ſee the article CAMEL.

GLAND, GLANDULA, in anatomy, a ſoft, ſpongy, lax kind of body; ſerving to ſeparate ſome particular *humour* from the maſs of *blood*. For a particular deſcription, ſee Syſtem of ANATOMY, Part I. Sect. 6.

GLANDERS, a filthy diſeaſe in a horſe, conſiſting in a corrupt ſlimy matter, running from the noſe, of a different colour according to the degree of the malignity, or as the infection has been of a ſhorter or longer continuance; being white, yellow, green, or black, ſometimes tinged with blood. For the cauſes and methods of cure, ſee Syſtem of FARRIERY, Claſs 8. Sect. 24.

GLANS, in anatomy, the tip or button of the *penis*, or that part covered with the prepuce, called alſo *balanus*. See Syſtem of ANATOMY, Part III. Sect. 24, Plate X, *fig*. 1. letter L.

GLANS is alſo uſed to denote the tip or extremity of the *clitoris*, from its reſemblance, both in form and uſe, to that of the penis. See Syſtem of ANATOMY, Part V. Sect. 12, and Plate X. lower diviſion, *fig*. 1. letter K.

GLASS, a tranſparent, brittle, factitious body produced from ſand melted in a ſtrong fire with fixed alkaline ſalts, lead, ſlags, &c. till the whole becomes perfectly clear and fine. The word is formed of the latin *glaſtum*, a plant called by the Greeks *iſatis*, by the Romans *vitrum*, by the ancient Britons *guadum*, and by the Engliſh *woad*. We find frequent mention of this plant in ancient writers, particularly Cæſar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with glaſtum, guadum, vitrum, &c. i. e. with the blue colour procured from this plant. And hence, the factitious matter we are ſpeaking of came to be called *glaſs*; as having always ſomewhat of this bluiſhneſs in it. At what time the art of glaſs-making was firſt invented, is altogether uncertain. Some imagine it to have been invented before the flood; but of this we have no direct proof, though there is no improbability in the ſuppoſition; for we know, that it is almoſt impoſſible to excite a very violent fire, ſuch as is neceſſary in metallurgic operations, without vitrifying part of the bricks or ſtones wherewith the furnace is built. This indeed might furniſh the firſt hints of glaſs-making; though it is alſo very probable, that ſuch imperfect vitrifications would be obſerved a long time before people thought of making any uſe of them. Neri traces the antiquity of glaſs as far back as the time of Job. That writer, ſpeaking of the value of wiſdom, chap. xxviii. verſe 17. ſays, that gold and *cryſtal* cannot equal it. But this word, which Neri will have to ſignify factitious glaſs, is capable of a great many different interpretations, and properly ſignifies only whatever is beautiful or tranſparent. Dr. Merret will have the art to be as ancient as that of pottery, or the making of bricks, for the reaſons already given, viz. that by all vehement heats ſome imperfect vitrifications are produced. Of this kind undoubtedly was the foſſile glaſs mentioned by Ferant. Imperator. to have been found under-ground where great fires had been. But it is evident, that ſuch imperfect vitrifications might have paſſed unnoticed for ages; and conſequently we have no reaſon to conclude from thence, that the art of glaſs-making is of ſuch high antiquity.

The Egyptians boaſt, that this art was taught them by their great Hermes. Ariſtophanes, Ariſtotle, Alexander, Aphrodiſeus, Lucretius, and St. John the divine, put it out of all doubt that glaſs was uſed in their days. Pliny relates, that it was firſt diſcovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a ſtorm at ſea; who being obliged to continue there, and dreſs their victuals by making a fire on the ground, where there was great plenty of the herb kali; that plant, burning to aſhes, its ſalts mixed and incorporated with the ſand, or ſtones fit for vitrification, and thus produced glaſs; and that this accident, being known, the people of Sidon, in that neighbourhood, eſſayed the work, and brought glaſs into uſe; ſince which time the art has been continually improving. Be this as it will, however, the firſt glaſs-houſes mentioned in hiſtory were erected in the city of Tyre, and here was the only ſtaple of the manufactory for many ages. The ſand, which lay on the ſhore for about half a mile round the mouth of the river Belus was peculiarly adapted to the making of glaſs, as being neat and glittering; and the wide range of the Tyrian commerce gave an ample vent for the productions of the furnace. It appears, however, that before the conqueſt of Britain by the Romans, glaſs-houſes had been erected in this iſland, as well as in Gaul, Spain, and Italy. Hence, in many parts of the country are to be found annulets of glaſs, having a narrow perforation and thick rim, denominated by the remaining Britons *gleineu naidreedh*, or *glaſs adders*, and which were probably in former times uſed as amulets by the druids. It can ſcarcely be queſtioned that the Britons were ſufficiently well verſed in the manufacture of glaſs, to form out of it many more uſeful inſtruments than the glaſs-beads. Hiſtory indeed aſſures us, that they did manufacture a conſiderable quantity of glaſs veſſels. Theſe, like their annulets, were moſt probably green, blue, yellow, or black, and many of them curiouſly ſtreaked with other colours. The proceſs in the manufacture would be nearly the ſame with that of the Gauls or Spaniards. The ſand of their ſhores being reduced to a ſufficient degree of fineneſs by art, was mixed with three fourths of its weight of their nitre (much the ſame with our kelp), and both were melted together. The metal was then poured into other veſſels, where it was left to harden into a maſs, and afterwards replaced in the furnace, where it became tranſparent in the boiling, and was afterwards figured by blowing, or modelling in the lath, into ſuch veſſels as they wanted.
